Her present trouble commenced about seventeen months ago. At that time, while pregnant with her last child, both legs swelled, the left much more than the right. A great deal of pain accompanied the swelling. The pain and swelling diminished after the birth of her child, but there remained a lump in the left popliteal space. In May, 1891, this began to be very painful, the pain being sharp and shooting in character. Soon after this the tumor also began to increase in size until it now extends from the top of the calf nearly to the groin. In

Brazil she consulted both native and English physicians, and they decided that amputation at the hip-joint was the only possible means of relief, and advised her to come to the United States to have it done. Her health has improved on the voyage from Brazil. She arrived in this country only a few days ago. A slight systolic cardiac murmur is heard over the base of the heart. The tumor measures twelve and five-tenths inches in length, and the circumference of the lower part of the thigh is twenty-three inches. The lymphatics in the groin are not enlarged. The pains are now dull in character and not as severe as they have been. Her digestion is good. She is, unfortunately, five months pregnant.

Having now given you the history of her case, so soon as the patient is brought in you will observe that the tumor extends well up toward the hip, but that there is still room for a flap between the tumor and the joint. You would naturally, therefore, ask me, Why not spare her the more severe operation of amputation at the hip-joint itself and amputate at the junction of the upper and middle thirds of the thigh? My answer is this: The tumor is undoubtedly a sarcoma. I fear that it has

originated from the bone or its periosteum—an osteo-sarcoma—and if so, the probabilities are that the entire bone is infected, and, therefore, to leave the upper portion of it would be, in all probability, to leave a source of infection from which the disease would start anew and destroy her life. Even if the bone is not involved, the soft parts are infiltrated so high up that there is not room for flaps of undoubtedly healthy tissue for a thigh amputation; hence the operation must be at the hip-joint or not at all. I am very loth to do any operation at all, the danger is so great. In addition to that, in this special case her present pregnancy creates so large an additional percentage of danger that I would gladly do no operation.

The question will then naturally suggest itself to you, Why not wait until after her confinement? or, Why not induce premature labor? As to the first: It would be necessary to wait four months for the completion of her normal term of pregnancy and at least one month for the puerperal period to pass. These five months might be cut down to four, possibly, by inducing premature labor at the eighth month; but not only do we not know what her condition might be after labor, whether premature or at term, but the disease, in all probability, in from four to five months from now would be so far advanced that I should then decline to do any operation. To induce labor now and to wait for a month to pass would be a possibility; but, inasmuch as we are not at all certain that she will abort after the amputation, I think we are justified in trying to save the lives of both mother and child; moreover, this is her own strong desire. Abortion will depend chiefly upon whether the operation can be made aseptic. If sepsis follows, abortion will almost surely occur; but if the wound runs an aseptic course, I think we shall probably avoid this calamity.

The *reasons* for amputation at the hip are twofold: First, traumatism; secondly, some new-growth—especially osteo-sarcoma. Occasionally other causes exist, but practically the traumatism and these pathologic causes cover more than nine-tenths of the cases. The *dangers* of the operation are threefold: First, and foremost, hemorrhage; secondly, shock; and thirdly, the later danger of sepsis, with all its complications. These are especially prone to follow operation at the hip-joint, on account of the lowered vitality of the system after operation, the enormous surface that is exposed, and the difficulty of preventing infection from the urine and feces.

I. The means by which *hemorrhage* is met are varied. First, the older methods of ligating the superficial and deep femoral arteries and veins prior to amputation; or compression of the abdominal aorta, which, as I have told you, was first devised and done by my predecessor, Professor Joseph Pancoast. Both of these, however, have great disadvantages. Ligation of the femoral vessels obviates hemorrhage from these vessels in the anterior flap, but it does not at all control hemorrhage from the gluteal, the sciatic, the obturator, and the circumflex and numerous muscular branches in the posterior flap. Compression of the aorta exposes the patient to dangerous pressure on the solar plexus or on the viscera, and, in addition, in our present case, is absolutely ruled out by her pregnancy.

Secondly, a few years ago Dr. Frank Woodbury,[1] a graduate of this school, proposed to insert the hand into the rectum and compress the common iliac artery. Soon afterward Van Buren, of New York, repeated the proposition. This, I believe, has never been done; but it possibly suggested a mechanical means which has answered a good purpose in several cases—Davies's lever. This English surgeon, following out the same idea, proposed to use a long, well-rounded, and smooth ebony stick, which might be compared to a couple of feet of broomstick. This was inserted in the rectum, and by lifting the handle, the other end being over the common iliac artery, this vessel could be compressed. Injury to the rectum, however, and the want of absolute reliability have caused this method to be viewed with only moderate favor.

Thirdly, the Furneaux-Jordan method. A compress is laid over the external iliac artery just above Poupart's ligament, and a band of elastic tubing is passed between the thighs, carried inside the tuberosity of the ischium below and within the crest of the ilium above. When the tubing is drawn sufficiently tight it arrests the pulsation in the external iliac artery by its pressure. I have tested this method repeatedly on the living model, and I confess that it has not given me any satisfaction; I have had great difficulty in controlling the artery.

Fourthly, Trendelenburg proposed to pass a stout pin under the femoral vessels and compress them by an elastic tube wound around the two extremities of the pin in a figure-of-eight.

You will notice that all these methods were open to one of two objections: if they arrested the blood both in the anterior and posterior parts of the thigh, they were objectionable on mechanical grounds by reason of the possible injury to the solar plexus, the intestines, or the rectum; or if they compressed the vessels in the anterior flap alone (the external iliac or the femoral), they were objectionable because of the great hemorrhage from the posterior flap. It was reserved for an American surgeon—a gentleman who has done me the honor to come from New York and be present at the operation to-day—Professor John A. Wyeth, to devise what is undoubtedly the best method, and, in fact, what I think we may call now the only method of hemostasis in amputation at the hip-joint. In addition to these methods of preventing hemorrhage, Erskine Mason proposed that, as far as possible, we should save the blood that is in the leg by Esmarch's bandage. In some cases the entire limb can be Esmarched from the toe to the groin, but in our present case it will not do to apply the Esmarch bandage higher than the lower border of the tumor, otherwise some of the sarcomatous elements might be driven into the circulation. Wyeth's operation is done as follows:

Two stout pins, twelve inches long and one-quarter of an inch in diameter at the head, are passed through the upper part of the thigh. The object of these pins is to hold in place a piece of elastic tubing which is wound tightly around the thigh just above them; the tubing will constrict all the bloodvessels in the entire thigh, and is prevented from slipping down by means of the pins.

[1] The American Journal of the Medical Sciences, January, 1874, p. 131.

The exact place of the pins is not very important, but they must be passed through the tissues at points where they will not injure any large vessels or nerves. The first one is passed about one and one-half inches below the anterior superior spine and slightly to its inner side and emerges just back of the trochanter major. The second one is passed an inch below the spine of the pubes internally to the saphenous opening and emerges just in front of the tuberosity of the ischium. Elastic tubing, half an inch in diameter, is then wound five or six times around the thigh, and is secured by stout forceps, or, better, by tying it. This tubing should not be ordinary white-rubber tubing, which is not very elastic, but should be of pure rubber. The control of the hemorrhage by this method, as you will see, must be absolute. Do not make one mistake: when I make the circular amputation you will see a large amount of blood flow out, but this will be wholly from the leg and not from the trunk; so soon as this has escaped the hemorrhage will entirely cease. About five inches below Poupart's ligament a circular incision is made through the skin and the superficial fascia; this is then dissected back, as a cuff, until the level of the lesser trochanter is reached; the muscles are then divided circularly down to the bone, and the bone is sawn off. Dr. Wyeth has made the happy suggestion that, when the bone is bare, instead of dividing it at the same level as the muscles, the tissue be stripped down for several inches and the bone sawn much lower down; the protruding part of the bone then serves as a handle for manipulation. This is far superior to sawing the bone at the lesser trochanter and seizing the stump of the bone with the lion-jawed or other forceps.

The next step is to secure the bloodvessels. The principal ones will be the superficial and deep femoral arteries and veins, in front, just under the deep fascia. Posterior to the bone, along with the sciatic nerve, run the sciatic vessels; externally, toward the gluteal region, the gluteal vessels, and lower down, the circumflex. Internally, at about the middle or a little posteriorly, lies the obturator. Besides these there is a large number of muscular branches which cannot be found until the elastic tubing is gradually loosened, after the important vessels have been secured. The vessels being all tied, even down to the smallest spouting branches in the muscular tissue, the elastic tubing, which has been partially released, is now removed and the pins drawn out. The upper portion of the femur is then dissected loose from the soft parts, hugging the bone as closely as possible, so as to avoid dividing any large vessels. The muscles are then cut loose from the trochanters, and the capsule of the hip-joint is exposed and opened. The ligamentum teres is now severed and the entire upper extremities of the bone removed.

II. The second danger, as I have mentioned, is *shock*. This is met in several ways. First, our patient has had an ounce of brandy and one-twentieth of a grain of strychnine. Secondly, I shall operate, as you observe, with the patient in a Trendelenburg chair; by means of this I can at any moment not only keep the patient horizontal, but, if I choose, I can put the head lower than the hips at the touch of a spring. Thirdly, in any serious operation the chilling of the patient from the necessary exposure of the person becomes a matter of great moment; especially is this true in an amputation so high up as the hip-joint. Accordingly, I have had both of my patient's arms, the right leg, and the entire body well wrapped in a thick layer of raw cotton kept in place by bandages. This is particularly necessary in using Trendelenburg's chair, which is narrow and cannot accommodate any hot-water bottles or other means of artificial heat. Fourthly, I have digitalis, the galvanic battery, and hot enemata all ready for use should they be required. In spite of all these, however, the shock must be severe. One cannot remove nearly one-fifth of the entire body without it.

III. The third danger is *sepsis*. I can dismiss this in a very few words. The leg, the buttock, and the abdomen have all been prepared as is usual in all my operations. This has been done for two days in succession, in order to obtain absolute asepsis. Secondly, the bowels have been opened gently and the rectum washed by an enema of warm water. Thirdly, the vagina has been disinfected by a douche of bichloride of mercury (1 : 2000), followed by hot water, and, to avoid a sudden possible opening of the bowels or any vaginal infection, an antiseptic towel has been secured over the vulva.

The patient is now on the chair; an aseptic sheet is under her, another one over her body, and a third envelops the right leg, which will be held by one of the clinical assistants. The steps of the operation are followed precisely as I have given them to you.

The operation being completed, let me say a few words in reference to it. The wrapping of the person of the patient in cotton is, I think, a matter of a great deal of importance in preserving the body-heat. It is very evident that she has not suffered nearly so much from shock as she otherwise would have done. I have operated as quickly as I could consistently with thoroughness. No operation must be done so quickly that it is done badly; but if done well, the more quickly it is done the better. You have seen, however, that the operation has taken fifty minutes. Two steps caused delay: first, the separation of the soft parts from the bone, and secondly, the ligation of the numerous vessels. In any other case I should not separate the soft parts, as I did here, by a knife. I should prefer the scissors, which, to a certain extent, would crush the small vessels; or, still better, I should be disposed to strip up the periosteum, in order to avoid the numerous small vessels which have taken so much time both in finding and ligating. Of course, at the linea aspera the tissues must be divided by the knife or scissors. One vessel, you especially noticed, was troublesome. It lay just outside the capsule in a wound of great depth, and was difficult to find and seize separately from the capsule. Should I ever have occasion to amputate at the hip again I should undoubtedly prefer to slit up the soft parts on the inside if need be, or if dividing the muscular tissues about the great trochanter gave trouble, to slit them at the outside—these additional incisions practically counting for nothing in healing and for much in facility of dealing with hemorrhage or with the muscles.

I cannot express too high an opinion of Dr. Wyeth's method of primary hemostasis. Not one drop of blood was lost from the trunk until after the large vessels were secured. On relaxing the compression of the tubing, of course, a large number of vessels required ligation, and

then after removal of the bone quite a number more, so that thirty-three ligatures in all were required. This large number was probably due to the great vascularity of the thigh, as the tumor required a large amount of blood for its growth. I think it probable that the patient lost about from eight to ten ounces of blood during the later securing of the vessels and enucleation of the bone. Dr. Wyeth's idea of a low amputation of the bone is a very happy one, the bony handle being very satisfactory. Whether the stripping up of the periosteum from the bone in order to separate the soft parts with less hemorrhage would be a source of danger has occurred to me. I shall ask my assistant, Dr. Coplin, to examine the periosteum of the upper part of this bone in order to determine whether there is any sarcomatous infiltration. If there is, it precludes at once the propriety of stripping up the periosteum.

If there is no sign of any such infiltration, the stripping up of the periosteum would not only avoid the danger by diminishing the hemorrhage, but would also have the possible advantage that in this partially complete periosteal tube there may be developed a more or less tough and resisting substitute for bone, which may make the wearing of an artificial limb less irksome. In most hip-joint amputations, an artificial leg can be worn only for a few hours each day, the rest of the time patient going about on crutches.

Two drainage-tubes have been placed in the wound, you notice, at both the external and internal extremities of it, both reaching up to the acetabulum. In a wound of such enormous surface and so very deep as this, drainage is essential, but the tubes may be removed at the end of two or three days, so that no sinus will remain and no avenue of deep infection exist.

The mortality of amputation at the hip-joint is very great. It is, perhaps, the gravest operation in all surgery. You will find in the *International Encyclopedia of Surgery* (i, 684) a table, prepared by a former assistant of mine, Dr. F. C. Sheppard, which contains the largest number of cases ever gathered together, 633 in number. Let me give you simply three summaries: First, in military surgery there were 238 cases of hip-joint amputations, with an average mortality of 87 per cent. Among these, primary and intermediate operations give the frightful mortality of 93 per cent.—only 7 out of 100 recovered! Amputation at the hip, therefore, during a campaign is almost equivalent to a death-warrant.

Secondly, in civil practice, after traumatism, including gunshot wounds, there were 71 cases, but the death-rate fell at once to 66 per cent. by reason of the better care and earlier attention and the absence of the hardships and privations inevitable during war.

Thirdly, and more encouragingly, there were 276 cases of amputation for pathologic causes, with an average mortality of 40 per cent. At best you see, therefore, our patient has to face a terrible risk, and, in view of her pregnancy, an exceptionally large risk.

March 10, 1892. The night after the operation, for about forty-eight hours, the patient suffered from traumatic delirium, although her temperature only rose to 100.8°. With this delirium she entirely lost control of the bladder. The greatest care was taken to prevent, if possible, infection of the wound by the urine. The inner drainage-tube was removed on the second day. No general infection took place, but by the end of the third day some pus showed itself in the track of the inner drainage-tube and infected the outer one soon afterward. The outer one was retained for several days —first, on account of a very abundant serous oozing, and later on account of the local suppuration. There was not, however, any general infection, and the temperature never rose to 100° after the first twenty-four hours. The flaps united excellently, except in the track of the drainage-tubes.

At no time was there the least indication of any disturbance of her pregnancy. This I attribute to the absence of general septic infection; had it taken place I have no doubt that abortion would have followed the high fever and general constitutional disturbance that would have attended it.

For the first forty-eight hours especially, the pain was very severe in the amputated leg, particularly in the foot-sole, and morphine in small doses was required to relieve it. The phantom leg was raised from the bed and held suspended in the air. Removal of the sutures seemed to increase its apparent reality, and up to the present time (March, 1892) the leg remains still as vivid as before. The position of the leg at present varies somewhat with the position of the stump. It is always, however, to some extent in advance of the stump—*e.g.*, when she is lying upon the bed it is a little above the bed. Usually the knee is bent, and the knee itself has been rather vividly perceived. Within the last week or ten days the leg has begun to shorten—not that the foot is attached, for instance, to the middle of the calf, but the entire leg seems to be shortening in its length. The pain is still felt occasionally in the foot-sole and sometimes shoots up from the lost foot to the stump.

Should I have occasion to repeat the operation, I should certainly use but one drain, placing that externally to avoid the possibility of infection.

MEDICAL PROGRESS.

Successful Operation for Cerebral Abscess.—MURRAY (*British Medical Journal*, No. 1624, p. 333) has reported the case of a girl, five years old, who, fourteen days after having been struck by a poker upon the right side of the head, presented uncontrollable twitching of the left arm and left side of the face. The movements continued for half an hour without loss of consciousness. Two other like attacks occurred on the same day and another subsequently. The seizures began with shaking of the left arm, followed by movements of the fingers; then the left side of the face became involved and the eyes rolled about. Progressive loss of power in the left hand was observed after the first attack. The hand became extended at the metacarpo-phalangeal joints and flexed at the interphalangeal joints. Sensation was unimpaired. The temperature was 98°. A small, sloughing scalp-wound was found in the right parietal region, in a situation corresponding with the junction of the upper and middle thirds of the fissure of Rolando. Through this wound a probe could be passed into the cranial cavity. Operation having been decided upon, a three-quarters inch disc of bone was removed at the site

of the wound. The dura mater was found to be torn; the cerebral structure was soft and sloughing and without pulsation. A probe introduced entered an abscess-cavity from which a dram of viscid pus was evacuated. The cavity was irrigated with a 1 : 5000 mercuric chloride solution; a small piece of sloughing tissue was removed, and a drainage-tube was introduced. Pulsation became evident at the end of a week. At the end of two weeks the drainage-tube had by gradations been entirely removed. The seizures did not recur. Power returned to the left arm and hand. Bilateral optic neuritis was discovered, but this subsequently disappeared.

The Non-contagiousness of Leprosy.—In a communication to the *New York Medical Record*, No. 1113, p. 276, Dr. L. Duncan Bulkley presented the following conclusions concerning leprosy, based upon considerable observation:

1. There is no warrant for the popular terror surrounding the name of "leprosy" as a disease.

2. The disease is not contagious in the ordinary acceptance of the term, as applied to such diseases as smallpox, scarlatina, or syphilis.

3. Leprosy is probably due to the presence of a bacillus.

4. There is strong reason to suspect that it may first be introduced into the system by the way of food, and fish is the most likely of all substances to furnish and convey the poison.

5. There is evidence that when acquired, the disease may, under favorable conditions, be transferred from one person to another.

6. Heredity probably accounts for a share of the cases, but the disease is not necessarily transmitted by inheritance.

7. Inoculation with leprous matter may be the means of conveying the disease, when all the conditions are favorable.

8. There are far more and greater reasons for the restriction of syphilis and tuberculosis by isolation and segregation than for the necessity of these regulations in regard to leprosy.

Poisoning by Balsam of Peru.—Lohaus (*Berliner klin. Wochenschr.*, No. 6, 1892, p. 130) has recorded the case of an infant, six days old, to see which he was called on account of convulsions. He found the child covered with sweat, crying, and evidently in great distress. On inquiry, it was learned that the infant was nursed by its mother, but that the stools were not normal. They were thin, greenish, and contained mucus. The child was restless and refused to take the breast. On the following day it was quieter, but moaned. The skin was wet; the lips were cyanotic; from the mouth exuded brownish, viscid mucus, with a peculiar ethereal odor. The pulse was rapid and feeble; the pupils were small. On investigation, it was elicited that the mother had been making applications of balsam of Peru to the nipples to prevent the development of fissures, simply wiping the nipples prior to nursing. In consequence, the infant got a small quantity of balsam of Peru at each nursing. As it became restless, the frequency of application to the breast was increased. The symptoms grew progressively worse, and the child died. An autopsy was not permitted, but it is believed that the balsam taken with the nourishment gave rise at least to an intense gastro-intestinal catarrh.

Linear Craniotomy.—At a meeting of the French Academy of Medicine, Prengrueber (*Münchener medicin. Wochenschr.*, No. 5, 1892, p. 80) reported the successful performance of linear craniotomy in a case of simple idiocy in a boy nine years old, without morbid hereditary predisposition, in whom development was retarded after the eighteenth month of age, the child learning to walk only at three, being filthy, and unable to read or write, and behaving like one of three or four. The cranium, elongated vertically, presented an elevation in the course of the fronto-parietal suture. The frontal and parietal fossæ were entirely obliterated. The cranium was asymmetrical, the left side being less well developed than the right. A strip of bone, a little more than an inch wide and about four inches long, was removed from the left side of the cranium about an inch from, and parallel with, the sagittal suture. Corresponding to the elevation at the fronto-parietal suture a thickening of the bone, directed inward, was found exerting pressure upon the brain. The offending structure was removed. The primary result was most satisfactory. Too little time had elapsed to warrant any opinion as to the ultimate result.

Attenuation of Tubercle-bacilli.—Failing in attempts to inoculate hens with tubercle-bacilli obtained from man, Gramatschikoff (*Centralbl. f. allgem. Pathol. u. patholog. Anat.*, 1892, ii, No. 25, p. 1057) sought to determine the nature of the changes that took place in the bacilli when introduced into the organism of hens. With this end in view, he introduced into the peritoneal cavities of hens pure cultures of tubercle-bacilli contained in parchment paper, in animal membranes, or in glass tubes closed by permeable membranes. The paper, membranes, or tubes, were removed after variable intervals, and the contained bacilli cultivated upon glycerin-agar and introduced into the eyes of rabbits. By this means it was possible to obtain tubercle-bacilli, of which the virulence was attenuated in a degree corresponding to their length of residence in the organism of the hen. Some were still capable of inducing a general tuberculosis, but the process pursued a slower course than usual. In others, only a local lesion developed, and this underwent spontaneous cure.

Gunshot Injuries of the Spinal Cord.—Vincent (*Revue de Chirurgie*, No. 2, 1892, p. 89) has recorded three cases of gunshot wound of the spinal cord treated by trephining, of which two terminated fatally. From a study of these and of thirty other cases collected from various sources, he expresses the view that while such injuries are unquestionably grave, they are not necessarily fatal. There is evidence that in some cases surgical intervention has contributed to the successful issue. If the lesion involve the spinal column on its posterior or lateral aspects, in an accessible situation, and there be no visceral lesion, abdominal or thoracic, imperilling life, the wound should be exposed throughout its extent, to determine the character of the injury, to remove foreign matters capable of causing compression or irritation of the cord, and if necessary to trephine the

spinal column. In some cases the operation may prove futile, but aseptically performed it is innocuous.

Cystoscopy.—From a consideration of the subject of cystoscopy, MEYER (*N. Y. Medical Journal*, No. 689, p. 174) concludes that the procedure should be practised in all obscure conditions of the bladder or kidneys, before operative interference is resorted to. Certain conditions render cystoscopy impracticable. The manipulation is simple and harmless, though its successful execution requires experience. It should be employed after all other means of diagnosis have been exhausted. It seems probable that in the future it will be possible to catheterize the ureters, so that the urine of each kidney may be separately examined. By observation the relative work done by either kidney may be approximately determined. The operating cystoscope may afford the means of therapeutic application under direct observation.

Transmission of Tuberculosis by the Seminal Fluid.—At a meeting of the Society of Anatomy and Physiology of Bordeaux, SOLLES (*Journal de Médecine de Bordeaux*, 1892, No. 5, p. 52) reported the results of experimental inoculation of two guinea-pigs, the one with the fluid expressed from the testicle of a tuberculous subject, and the other with the spermatic fluid obtained from the seminal vesicle of another tuberculous subject. In the first, the induration at the site of inoculation slowly disappeared, without involvement of adjacent glands, and the animal recovered. In the case of the second guinea-pig, fatal general tuberculosis developed. The evidence, in so far as furnished by a single case, points to the hereditary transmissibility of tuberculosis.

The Transmissibility of Carcinoma.—At a meeting of the Académie des Sciences, DUPLAY and CAZIN (*La Médecine Moderne*, 1892, No. 8, p. 113) reported the results of investigations as to the inoculability of carcinoma. In a first series, comprising twenty-two observations, they inoculated, either subcutaneously into the peritoneum or into the blood, rabbits, guinea-pigs, and dogs, with carcinomatous material obtained from man, in all instances without positive results. In a second series of experiments they inoculated animals with carcinomatous material obtained from dogs, but without producing more than a local inflammatory lesion, which underwent absorption. Attempts to transmit carcinoma from dog to dog also failed.

A Case of Myxedema of Syphilitic Origin.—At a meeting of the Association of Surgeons of Berlin, KÖHLER (*Deutsche medicin. Wochenschr.*, 1892, No. 6, p. 122) reported a case of myxedema in a woman fifty years of age, who likewise presented manifestations of syphilis. Anti-syphilitic treatment was followed by the disappearance of the specific symptoms, as well as of the myxedema. An explanation is sought in a possible syphilitic involvement of the thyroid gland.

Toxicity of the Serum of the Blood in Puerperal Eclampsia.—In two cases of puerperal eclampsia CHAMBRELENT (*La Semaine Méd.*, 1892, No. 12, p. 89) found that the toxicity of the serum of the blood was increased, while the urotoxic coëfficient was diminished. These observations are confirmatory of the view that puerperal eclampsia is dependent upon auto-intoxication.

THERAPEUTIC NOTES.

The Treatment of Cystitis with Mercuric Chloride.—GUYON (*Annal. des Mal. Génito-urinaires*, xi) recommends mercuric chloride in the treatment of cystitis. The results are especially good if the cystitis be tuberculous. Irrigation or instillation may be employed. The mercurial solution may vary from 1 : 5000 to 1 : 1000. At first from twenty to thirty drops are instilled, by means of a syringe, into the prostatic urethra, the quantity being gradually increased to a dram. The bladder must be evacuated after each instillation. In gonorrheal cystitis, good results were obtained from instillations of silver nitrate 1 or 5 : 100.—*Münchener med. Wochenschr.*, 1892, No. 5, p. 81.

Ointment for Sycosis.—

℞.—Acid. tannic. . . . . gr. xxiv.
Sodii lactat. . . . . ʒj.
Zinci oxidi } . . āā ʒiij.
Amyli }
Vaselini . . . . . ℥j.—M.
Ft. unguent.
S.—Apply twice daily to the skin carefully shaved.
ROSENTHAL, *L'Union Méd.*

Injections of Gray Cerebral Matter in the Treatment of Neurasthenia.—At a meeting of the French Academy of Medicine, PAUL (*L'Abeille Méd.*, 1892, No. 9, p. 65) reported the utility of subcutaneous injections of sterilized emulsions of the gray matter of the brain of the sheep in the treatment of neurasthenic conditions. In eleven cases in which the procedure was employed good results were obtained; the remedy was well borne; the injections occasioned no unpleasant complications.

For Coccydynia.—The following suppository employed at bedtime will afford relief from the pain of coccydynia and permit sleep:

℞.—Ext. belladonnæ . . . gr. ¼.
Ext. hyoscyami . . . gr. ¾.
Iodoformi . . . . gr. ¾.
Ol. theobromæ . . . gr. xx.—M.
WHITLA.

For the Cough of Acute Bronchitis.—

℞.—Apomorphinæ hydrochlorat. . gr. j.
Acid. hydrochloric. dil. . . ♏x.
Syrup. . . . . fʒiv.
Aquæ menth. pip. . . . fʒjss.—M.
S.—From one-half to one teaspoonful every two hours.
WHITAKER.

For Acute Angina.—

℞.—Sodium benzoate . . . gr. x.
Tincture of benzoin . . fʒss.
Infusion of rose leaves . . fʒj.—M.
S.—Use frequently as a gargle.

SATURDAY, MARCH 26, 1892.

THE ETHICS OF PROPRIETARY PREPARATIONS.

THE subject of this article is suggested by a letter from a correspondent written in answer to our own letter declining to publish an article that seemed to us liable to be misunderstood as an advertisement of a certain proprietary preparation. We do not question our correspondent's good faith; but in the belief that he has been misled, and with a desire to save others from being misled as he has been, we we shall try to speak plainly on the important issues involved.

For the sake of designating in our argument, without advertising it, a preparation such as our correspondent advocates, we will substitute the word *fraudine* for the name used by our correspondent.

Our correspondent says:

"There is a difference between patent medicines sold to the public, proprietary articles sold to anyone, and antipyrin, aristol, *fraudine*, and similar drugs introduced only to the medical profession, where we are made acquainted with the general character of them, as, for instance, *fraudine* being a coal-tar derivative, and where its discovery is due to the industry of some chemist outside of the medical profession. We surely are but at the beginning of this labor of chemistry, and the only stimulation chemists will have for such tedious work will be the pecuniary reward resulting not from the fact of the preparation being a secret—that makes one of the points of difference, for anyone can go to the Patent Office and learn the procedure—but from others being prevented from manufacturing the article for a number of years."

There is, we regret to note, considerable confusion and wavering in the minds of many members of the medical profession as to the attitude that should be assumed toward preparations of the classes named by our correspondent. "Medical ethics" rest upon no other foundation than that of ethics in general—the simple principle that there is a distinction between right and wrong. The acts prohibited in the written code adopted by the American Medical Association are not wrong because the code says they shall not be done; but the code says they shall not be done because they are wrong. They were reprehensible before the code was established, and to abolish the written prohibition will not make them commendable. Every honorable man whose state of civilization has advanced far enough to enable him to appreciate the distinctions on which their prohibition was based must, perforce, continue to avoid them.

If we are told that distinctions between right and wrong are hard to draw, we answer that religions, philosophies, and science have, in various language, expressed at least one simple and fundamental guide: That which is selfish is wrong. The good of all, not of one, is to be sought. Despotism in government, monopoly in economics, secrecy in medicine, are children of the same vice.

The physician occupies a unique relation to the public and to his patients. He is trusted with more than their fortunes—with their lives. He must think of their welfare before his own, or rather, find his own welfare in theirs. If he is not prepared to do this, he must not enter the sacred ministry of Hygeia. The thought of gain that might legitimately be entertained by those who labor in any other calling, save alone that of the minister of religion, may not enter the physician's mind. True, "the laborer is worthy of his hire," and the physician, like the pastor, must live; and to live, he must have the wherewithal to procure the necessaries of life; and to practise his profession usefully and intelligently, he must have books, instruments, and opportunities for study and research. All this requires money, and therefore, of course, the pastor must receive a salary, and the

physician is obliged to ask compensation for his services from those of his patients who are able to give such compensation. But from the element of profit-seeking that figures so largely in commerce and in some of the arts, the physician, like the pastor, must forever maintain himself purified.

In addition, he owes it as a duty to humanity to promptly make public for the benefit of all sufferers, present and future, any discovery he has made that may tend to throw light upon the causes or processes of disease, or to add to the resources of the profession and the public in preventing and combatting disease.

Furthermore, no useful discovery can be made by a physician at the present day unless he has in his possession knowledge that has come to him from the labors of others, unselfishly given throughout all the long ages of the history of the science and art of medicine. Having received this value from his predecessors and cotemporaries, he is bound to return an equivalent to his cotemporaries and successors. The knowledge he has been given came from the first, and the knowledge he can give belongs, of right, to the last.

From all these standpoints, therefore, the attempt to hold as secret or exclusive for the purpose of commercial profit, remedies or processes that the discoverer may deem to be more beneficial than those which are the common property of the profession, has always been regarded by the enlightened sentiment of medical men as nothing less than criminal. They cannot conceive that any true physician would be guilty of such a crime. Therefore it is that those who attempt to trade upon the alleged possession of secret processes of cure are regarded as charlatans and impostors. Therefore it is that no man may adopt the methods of charlatans and impostors and dream of retaining the respect or confidence of the profession whose holiest traditions he outrages.

What would the Church say to one who professed to have and to sell the secret of the soul's salvation?

Physicians dare not compromise with fraud; they must hold themselves free from the slightest suspicion of venality. "The greatest good to the greatest number" demands that they shall absolutely refrain from countenancing the secrecy that may envelop an alleged remedy, even by tacitly permitting its use. "To do a great right, do a little wrong"—even could great good follow, which in this instance would be impossible—is the argument of the special pleader, and of the devil. Much nobler is the sentiment, "If thine eye offend thee, pluck it out."

But even departing from the high ground of principle, and coming down to the very low level of expediency, let us consider whether or not it be expedient for the advancement of science and the promotion of the art of healing to use secret preparations or nostrums as remedies. By a secret preparation or nostrum we understand an alleged remedy, of which either the method of preparation or the true and exact composition is not made public. Quinine, for example, though perhaps prepared by a secret process, is not a nostrum. Neither does antipyrin nor acetanilide, nor thymol-iodide fall within this category. They are definite chemical compounds, and because the process by which one of them is made is in truth patented, it is on record. So-called "patent medicines" are not patented. They could not prove the "novelty" and "usefulness" that the law demands as a prerequisite to the issue of a patent. Their names are "trade-marked" or "copyrighted," but their composition is kept secret. To reveal it would be to reveal their fraudulent pretensions.

"Fraudine," *i. e.*, the drug referred to by our correspondent, concerning which all that is known is the bare assertion of its manufacturers that it is a "coal-tar derivative," is like the ordinary patent medicine in the absence of the necessary publicity involved in a true patent. It therefore falls within the prohibited category of nostrums or secret articles. The bald expression, a "coal-tar derivative," is therapeutically and pharmaceutically meaningless, and is as misleading as the ordinary quack's characterization of his nostrums as "purely vegetable." Strychnine and charcoal are both "purely vegetable," yet their therapeutic and toxic properties lie at the opposite poles of the pharmacologic sphere.

"Coal-tar derivatives" are many and various in composition, as in therapeutic properties and in toxic powers.

Kairin is "a coal-tar derivative," yet no careful physician will employ it in medicine, now that its toxicity has been so abundantly demonstrated. Suppose an enterprising firm of manufacturers, fortifying itself with certificates and reports (alas! so easily purchased), were to mix kairin with a number of inert substances, and put the mixture upon the market as an "American coal-tar deriva-

tive," having antipyretic and analgesic properties; would that justify the physician in prescribing it under the name of "antimorbine," when he would not be justified in prescribing it under its own name? How can he know that a preparation, concerning which neither the composition nor the process of manufacture is anywhere on record (and such is the case with *fraudine*), is not equally dangerous with the mixture we have supposed? As a matter of fact, at least one case of fatal poisoning by this very nostrum that our correspondent so extravagantly praises, is on record.

We have had in the so-called "gleditschine" a notable instance of what the unscrupulousness of manufacturers, presuming on the well-known gullibility of medical men, will lead them to do. Is it less reprehensible to mix acetanilide with sodium bicarbonate, and, while carefully refraining from making known the composition of the mixture, to allege it to be a new product with many wonderful virtues, than it was to mix cocaine and atropine, with the same careful secrecy and the same false allegations?

While, however, we deem it criminal for a physician to hold secret a medical discovery, and incompatible with the highest standard of professional conduct for him to patent a therapeutic invention, we do not and cannot object to a chemist's patenting anything that the laws of his country make patentable. We do not and cannot object to the chemist's entertaining the idea of profit, and laboring to attain large profit by honorable means. We do not and cannot object to the use by physicians of remedies of which the processes of manufacture are patented or secret, provided only that in every instance either the full process is of public record, or the true and exact composition of the finished product is made known. How else can one gain accurate knowledge of the effects of the medicines he administers? How else can he test the drug that is dispensed upon his prescriptions? How else can he be sure that the same thing is always furnished under the same name?

We would continue to use quinine, even if manufactured by a patented or by a secret process, because we have some means of learning whether or not the product offered us is what it purports to be.

So, too, antipyrin is subject to chemical analysis, or test, if not by physicians, at least by those competent to do such work, in the same manner as any of the drugs recognized by the Pharmacopeia is so subject. But the nostrum praised by our correspondent is not subject to such analysis, because those who prepare *fraudine* have nowhere informed analysts what it contains; and if they choose arbitrarily to alter its composition to-morrow, there is nothing to restrain them from so doing. There is no means even of ascertaining whether they aim to produce an invariable product; or, in the other event, of gauging the average variation, as we can do in the case of some of the variable preparations recognized by the Pharmacopeia.

Our correspondent cannot fail to see that we agree with every tenable point in his argument, but that as a whole his argument is like "the flowers that bloom in the spring"—it has "nothing to do with the case." Unless we are entirely misinformed—and our waste basket has been encumbered with much printed matter, a number of pocket-wallets, and some dozens of powders forwarded us by the Fraudine Company—the status of his pet nostrum differs from that of antipyrin and from that of thymol-iodide in vital points. Its composition is not known, its method of preparation is not recorded; it is not even patented, but like plain, non-professional, every-day quack preparations, is merely trade-marked.

For these reasons, we must decline to prostitute our reading-columns to its exploitation.

So much for the issues raised by our correspondent. The moral and legal questions involved in the practice of trade-marking and copyrighting the names of medicinal preparations, and a consideration of the attitude the profession should assume toward these questions, we defer for future discussion.

THE DISPOSAL OF TUBERCULOUS CATTLE.

THE appearance of tuberculosis in a herd of Jersey cattle, owned by a resident of Philadelphia, the method of diagnosis employed, and the measures taken to eradicate the disease, deserve more than passing notice, inasmuch as the whole subject bears an intimate relation to the public health. The herd was an exceptionally fine one; it was selected with the greatest judgment, and has been maintained under the best hygienic conditions. An ordinary physical examination would have failed to detect signs of disease. As a part of a plan to employ every measure available for determining the soundness of the cattle, it was resolved to subject them to a diagnostic test that has recently been the subject

of a good deal of heated discussion. Tuberculin was injected, and careful observations were made. Thirty per cent. of the herd reacted with a marked increase of temperature, which is considered as indicative of the existence of tuberculosis. In order to verify the correctness of the test, six cows were slaughtered, and of this number five presented macroscopic evidence of the existence of the disease in more or less decided degree; while in one animal there was some doubt, which will be set at rest by the results of a careful microscopic examination. If a critical examination of the pathologic specimens preserved for the purpose fully confirms the results already obtained (and of this there seems scarcely a doubt), the slaughter of the cattle will be continued until every suspected animal is destroyed.

Apart from the demonstration of the value of tuberculin as a diagnostic test, great importance attaches to the course of action taken in its relations to the public health. It is a well-known fact that a considerable percentage of cattle is more or less affected with tuberculosis. It is also well known that tuberculosis may be communicated to man by the consumption of the milk and flesh of cattle suffering from this disease. Tuberculosis is the great scourge of the human family, and therefore any plan that can measurably diminish the disease by abridging one of its sources should be adopted without delay.

The course to pursue, under the circumstances, is a plain one, but it must be orderly and systematically carried out, under legislative enactments. The Legislature has a clear and responsible duty to perform. The conservation of the public health is paramount to all other considerations. Let the Legislature authorize the rigid inspection of all cattle—not a happy-go-lucky examination, but one conducted by experts versed in the best methods of diagnosis. Let all cattle condemned be promptly slaughtered, and a periodic inspection be continued, with full authority to decide and to enforce its legitimate conclusions.

It is not expected, as in the present notable case, that the owners of the cattle shall suffer the loss. The public is to receive the benefit, and, therefore, the expense of eradicating the disease should be a public charge. By a just system of indemnification all objection to the arbitrary disposal of affected cattle will disappear. It will cost the State a large sum of money, but the benefit to be derived is immeasurably great, and far outweighs any money consideration.

NEWS.

TUBERCULOSIS IN CATTLE.

Tuberculin as a Diagnostic Agent.

THERE is no aspect of the subject of tuberculosis that is not important. There is probably none more important than the prophylaxis. As the disease is in no small degree transmitted by the milk and flesh of cattle, any means that facilitates its detection in and eradication from the source of food-supplies must command earnest attention. It is on account of the vital importance of the subject that we present herewith a detailed report of the proceedings in connection with the discovery of tuberculosis and the slaughter of some of the cattle of a herd of valuable animals, and the means taken to eradicate the disease. Not an insignificant feature of the investigation is the part played by tuberculin as a diagnostic agent. The movement inaugurated should mark a departure in hygienic methods of practice.

HISTORY OF THE HERD.—The Clairemont herd of Jersey cattle was established about 1882–83, and springs from a number of imported cows which were bought at that time. Frequent additions to the herd have been made, from time to time, of animals bought in New York, Baltimore, and Canada, and none but the choicest individuals have been selected, for which high prices have been paid.

All of the leading strains of Jersey bulls have been used, and to-day the Alphea, Rioter, Stoke-Pogis, Coomassie, St. Lambert, and Guilderoy blood is found represented by many splendid animals.

Every precaution has been taken to preserve the health of the stock and to increase their constitutional vigor. Inbreeding has never been practised, and the stables and animals have always been cared for in the best manner.

If good ventilation, the choicest of food, plenty of exercise, and pure water are potent factors in preserving the health of animals, this herd has been supplied with all of the conditions favorable to the most perfect health.

The herd has been regularly examined by experts, and the present outbreak of tuberculosis was discovered but a few weeks ago. In the rare cases in which the disease has heretofore been detected, the affected cattle have been destroyed at once, and their places in the stable disinfected.

By the use of tuberculin the disease was discovered in animals that seemed to be in perfect health, and it was not until this discovery that the heroic measures adopted were decided upon.

Experts hold that tuberculosis prevails to a great extent in many of the large herds of the country, and that it can be eradicated only by promptly killing all suspected animals. All agree that it is better to kill some suspected animals and find them free from tuberculosis, than to allow a single suspected animal to remain in a herd.

Mr. Gillingham's action is an example of public-spiritedness that has been seldom equalled, and the

public would profit immeasurably if others would follow a similar course. The sacrifice of animals worth thousands of dollars must command the warmest admiration.

Remarks by Dr. Pearson, *Assistant Professor of the Theory and Practice of Veterinary Medicine in the University of Pennsylvania.*

I was requested by Mr. Joseph E. Gillingham, several weeks ago, to examine a cow in his herd which did not seem to be doing well, and I found it suffering from tuberculosis. The animal was killed the next day, and the diagnosis was confirmed by the post-mortem examination. Thereupon I made a careful physical examination of the entire herd, and found five cows affected with the same disease, all of which were promptly destroyed. A short time after this, a fat cow that would not breed was killed for beef, and it was discovered to be in a highly tuberculous condition. This caused me to suspect that the disease might be more prevalent than we heretofore had reason to suppose, and with the object of detecting the affected animals it was decided to use tuberculin as a diagnostic agent. It is well known that tuberculosis in cattle is exceedingly difficult to diagnosticate, and that there are no physical signs by means of which we can recognize any but well-advanced stages of the disease. It is for this reason that tuberculin is so valuable as a diagnostic agent. The subcutaneous injection of a small quantity of tuberculin is followed by elevation of the temperature of a tuberculous animal, but not otherwise. These are, at least, the results that have been obtained by numerous foreign investigators, and by the Tuberculosis Commission of the Veterinary Department of the University.

Tuberculin has now been used on hundreds of cattle, and with the most satisfactory results. Of course, nothing is absolutely infallible, and there are a few cases on record in which the characteristic reaction to tuberculin failed to appear. But we must remember, in this connection, that many incompetent persons have experimented with tuberculin, and that of the vast literature of the subject some is untrustworthy.

It has also been said that tuberculin will cause a reaction in animals suffering from chronic inflammatory diseases other than tuberculosis; but it is well to call attention to the fact that tuberculosis frequently occurs in association with other diseases, and that in these cases the rise in temperature may have been due to undiscovered tuberculous lesions. That this may happen is shown by an occurrence in Germany. A cow was given an injection of tuberculin, and reacted characteristically; she was killed, and tubercles sought, but none were found. It was thought that the agent had failed, until the animal had been hung up and the vertebral column divided, when well-developed tubercles were found in the bones of the back.

In the few cases in which reactions followed the use of the agent and post-mortem examinations have failed to disclose the existence of tuberculosis, may not similar conditions have been present? In all, seventy-nine of Mr. Gillingham's cattle have been tested with tuberculin, and of these thirty have reacted in a manner that has been interpreted as indicating the existence of tuberculosis.

Of these, two have been killed, and were found to be diseased. After discovering how prevalent the disease probably was in the herd, the question of the disposal of the animals became the all-important one. Three courses were open: The animals might have been kept, as they were all apparently in good condition and appeared well, and many were yielding large quantities of milk; or they might have been sold, for they seemed to be in perfect health, and would undoubtedly have brought good prices; or, lastly, they could be killed, and thus the danger of contamination of the other animals and of the milk be removed. Mr. Gillingham did not, for a moment, consider any but the last method of disposing of the animals. As soon as tuberculosis was discovered, he ordered the affected cows destroyed, and the milk from animals known to have tuberculosis has never been sold or used. The remaining healthy animals will be placed in disinfected stables, frequently examined for incipient tuberculosis, and strictly kept from associating with suspected animals. In this way it is hoped that the progress of the disease will be checked, and the health of the remaining animals preserved.

Remarks by Dr. Guitéras, *Professor of Pathology in the University of Pennsylvania.*

It is seldom that an opportunity like the present offers for experimentation on so large a scale. Here, indeed, the public spirit of the owner of these animals has vied with the magnitude of the subject. The occasion is, therefore, one that well deserves earnest attention, and it may interest the public to have the problems here involved presented from their several points of view.

The facts are briefly these: A number of animals in a fine herd of cattle is suspected of being tuberculous. In a few of them the diagnosis has been confirmed by post-mortem examination. In others, apparently healthy, the suspicion rests mainly on evidence furnished by the use of tuberculin as a means of diagnosis. As you have heard, it is now proposed to kill the animals.

There are several lessons to be learned from the investigation of to-day.

1. The value of tuberculin as a means of diagnosis will be proven. When a physician pronounces a case to be tuberculous, he is nearly always right, because there is hardly a subject in medicine that has received more careful and successful study than this. Occasionally, however, the physician will find that his suspicions have been unfounded, or, more often still, he will find tuberculosis when it was not suspected. It appears that tuberculin can reduce very considerably the number of such errors. The experiments made in Karlsruhe, Dresden, and Dorpat, and in France, show that the masked tuberculosis of the lower animals may often be detected by means of tuberculin.

2. Our attention should be called to the example that is to be given to-day of an earnest and grave consideration of a question relating to the public health. Of all medical problems none equals in importance that of tuberculosis—a disease that causes one-seventh of the deaths of the human race. Whenever it can be clearly shown that its progress can be arrested in any direction, no sacrifice is too great if it brings about the desired end. Tuberculous cows are a menace to the public

health. The following facts will leave no doubt as to this. The meat of a tuberculous cow contains the microbes of tuberculosis. Even after such meat is cured by smoking or salting, it can by inoculation be successfully used to produce an experimental tuberculosis in some of the lower animals.

Another danger is that of transmission of the disease by means of milk. In many localities it has been found that ten per cent. of stall-fed cows are tuberculous. Of these, fifty per cent. will yield milk containing the microbes of tuberculosis—milk that can be inoculated into guinea-pigs and produce tuberculosis. Of course, the material thus used by the experimenter is placed under conditions the most favorable for a successful inoculation. In the natural course of events this is far from being the case. On the contrary, innumerable agencies, some of which are unknown, render the process of transmission of the disease much more difficult than it is in the hands of the experimenter. Hence it is that we do not all have tuberculosis. But we stand between this evident source of danger and the frightful mortality that I have mentioned. I will not leave this subject without saying that a temperature of 68° C., kept up for thirty minutes, will destroy all the bacilli of tuberculosis that may be present in milk.

It is not alone in the food-supply that the products of tuberculous cows may be brought to us. Indeed, it is probable that in the majority of instances we take in the tuberculous material by inhalation, and not by swallowing. The tuberculous material taken in by inhalation has more chances of taking root, as it were, than that which is swallowed.

And how is milk inhaled? By drying wherever it may fall, and being blown about with other particles of dust. Guinea-pigs can experimentally be made tuberculous by putting some dust under their skins; and if the dust is obtained from rooms in which tuberculous patients are being treated, the chance of a successful inoculation is much greater than in the case of dust taken from other apartments. The conclusion to be derived from this is that we should not allow tuberculous patients, human or otherwise, to make tuberculous dust.

3. We shall look forward with great interest for the result obtained by the destruction of these animals. How far will the desired end of eradicating the disease be attained? How far may the young cattle be already tainted? How far may the premises be infected?

It may be possible, by this experiment, to demonstrate how tenaciously the infecting material may adhere and be renewed about premises that have once been infected, or by what means it may be destroyed.

It is by no means easy to demonstrate the success of measures of disinfection of premises against tuberculosis. I would suggest that in carrying out measures of this kind attention should be paid to the removal of all classes of vermin existing about the premises, especially rodent animals, that might be the means of perpetuating the evil. I once saw what appeared to be a successful disinfection of a country house against tuberculosis, and it was signalized by the destruction and driving away for months of mice, bats, and insects. In disseminating the germs of disease there can be no doubt of the pernicious activity of these agents.

REMARKS BY DR. SHAKESPEARE, *lately U. S. Commissioner to Investigate Cholera in India and Spain.*

We learn from the census of 1880 that we possessed in this country about 43,400,000 cattle, 49,000,000 sheep, and 51,800,000 swine. Of these animals, it is the common experience that cattle and swine suffer most from tuberculosis. Passing by without remark the ravages of tuberculosis of swine, I shall briefly endeavor to show the importance of the subject as regards the interest of cattle breeders and dairymen, and point out its relations to the public health.

1st. *As to the extent of tuberculosis among cattle.*

The statistics concerning the extent of tuberculosis in cattle are exceedingly incomplete, and for some countries entirely wanting; but it may be safely said that whatever the figures they are far short of the real truth.

Taking all cattle of all ages and uses, including calves, a low estimate of the average percentage of those visibly affected with tuberculosis is two per cent. The highest percentage of disease is by common observation found to be among the milch-cows, and it ranges in different herds and localities, from three to ten or more times the general average. It will be within truth, therefore, if we say that in 1880 there were in this country 868,000 cattle affected with tuberculosis. Every bovine animal suffering from tuberculosis will ultimately die of the disease if it be not killed. This means a loss to the farmer (placing the value per head at twenty dollars) of $17,360,000 per annum. In 1880 there were 12,443,000 milch-cows. Estimating the percentage of disease among them at ten, a conservative figure, we find that 1,244,300 were tuberculous. Fixing the value per head at thirty dollars, we learn that the loss, if these animals were not sold in the shambles for beef, is $37,329,000.

2d. *Tuberculosis is highly infectious and contagious among cattle and swine.*

It is now universally recognized by competent veterinarians and pathologists that tuberculosis is virulently infectious and contagious among cattle and swine, and it is an established fact that as a rule higher-bred and well-cared-for herds suffer most from its ravages. Once started in a herd, unless the most vigorous and judicious means are early enforced for stamping it out, it bodes the slow but certain destruction of the majority, if not indeed of the whole. The infectious principle is contained in the material that comes from the diseased parts; that is, in the matter which is coughed up from the lungs, and is either swallowed or thrown off in the act of coughing. The bowels are often ulcerated. The excrement, therefore, contains the discharges from these ulcers, as well as the matter thrown off from the lungs which is swallowed. This infectious material has been, unfortunately, found to be highly resistant to the action of the ordinary natural agents of destruction, such as drying, freezing, and the like. The excrement and the matter expectorated, therefore, infects for a long time the stables and other places frequented by the affected animals, becomes dry, powdered, and rises in the dust, to be inhaled and swallowed by healthy companions, that in their turn contract the disease, and themselves form new centers of infection. It seems to be pretty clear also that sometimes, in cattle, the disease is transmitted to the offspring from a tuberculous bull,

who may be suffering from a concealed tuberculosis of the genital apparatus.

3d. *Absolute necessity for the enforcement of vigorous measures to eradicate the plague, and economy alone in their prompt and unstinted adoption.*

Experience has proved the utter uselessness of temporizing, by trusting to quarantine of visibly affected animals and disinfection of stables, etc. The only measure that promises any degree of certainty to arrest and prevent further ravages in a herd, is the prompt destruction of not only all visibly affected animals but also of *all suspected animals*, accompanied by as thorough a disinfection of the surroundings as is known to modern science. Mr. Gillingham has, in my opinion, in deciding to follow the course recommended, done well from the standpoint of advanced public spirit. But he has adopted a course which in the end—notwithstanding its great first cost—will most benefit his own pocket. *It is unquestionably the economical course.*

4th. *The constant danger to the public health from tuberculous cattle.*

I have now reached the most important part of this question for the general public.

Tuberculosis in the human being is possibly more prevalent than among cattle. It is estimated by reliable mortality statisticians that from one-fifth to one-seventh of all deaths are due to some form of tuberculosis. The disease is now recognized to be less hereditary in the human being than it is infectious. There is no fact better established in medicine to-day than that the human being who has no hereditary tendency whatever to tuberculosis can acquire the disease by taking into the system the infectious principle of the disease. One of the most frequent modes of infection in man is by inhalation. But it is also certain that in the laboratory the disease can be easily produced artificially in animals experimented on by way of the digestive canal.

There is ample evidence that a large percentage of tuberculous milch-cows produce milk that contains the infectious principle of the disease. The use of such milk for infants' food without boiling constitutes an undoubted danger that they may become infected. In fact, since tuberculosis in the human race has become better known it has been found that in infants and young children in some large cities the mortality from some form of tuberculosis is far greater than has been generally believed, amounting in some localities to one-fifth of the deaths in the young. The significant fact in this connection is that it is most frequently some part of the digestive passages that become first affected. In conclusion, I wish to say that the experience of Mr. Gillingham is by no means single or at all uncommon. It is, however, uncommon for one in his situation to adopt so wise a course. I wish to enforce his experience as one more of the numerous examples of the necessity for the general public in large cities to see to it that there is proper inspection of their meat and milk supplies.

Remarks by Dr. A. C. Abbott, *First Assistant in the Laboratory of Hygiene, University of Pennsylvania.*

Prior to the introduction of tuberculin by Koch, bacteriological studies were directed more to checking the spread of infectious diseases by means of vaccination with either modified organisms or their nutritive products than to the therapeutic employment of these substances in the treatment of disease already in progress.

The method employed by Pasteur for the treatment of rabies, which, in many respects, appears to be analogous to the method of Koch, though certain essential points are lacking to permit our making the positive statement, was the only therapeutic employment of what seem to be the products of growth of bacteria, or modifications of the substances composing the bacteria themselves. I say, seem to be, for we are not yet in a position to say that bacteria are the agents underlying the condition known as rabies.

Until the introduction of tuberculin the method in vogue for preventing the spread of infectious diseases was, in the main, that of causing a mild or modified form of a disease by inoculating the animal with the organisms concerned in its production after their virulent character had been so altered by chemical or thermal agents that they no longer possessed the power of producing the malady in its normal intensity. This modified attack often afforded immunity against a subsequent attack of the same disease.

Another common method aimed at causing certain indefinite reactionary changes in the tissues by the introduction into the animal of the chemical products of bacterial growth from which the organisms that had produced them had been carefully separated by filtration.

In both of these methods the application of high temperatures, particularly in the latter, was fatal to the success of the experiment, for the virtues of the immunity-affording substance that existed in the chemical products of these special bacteria, that had been studied in this direction, were entirely destroyed by these temperatures.

It is plain, therefore, that, unless the separation of the living and virulent organisms from the chemical products that were employed as a vaccine was perfect, it was quite possible to cause the appearance of fresh cases through these inoculations instead of checking the spread of the disease.

By the method employed in the preparation of tuberculin such an accident is not possible, for since its virtues are not destroyed by the action of heat of sufficiently high temperature to kill all living bacteria that might have been concerned in its production, this exposure to high temperature forms a regular step in the routine of its manufacture—a step intended to render the material harmless.

Whether we are justified in saying that the active principle of this substance, tuberculin, is the product of growth of the bacilli, or the bacterio-protein of the bacilli themselves, it is not at present possible to say with certainty, as in its manufacture both substances are to a degree spared. It seems reasonable, however, to consider the systemic reactions that appear in tuberculous animals after inoculation with this agent as due, in all probability, to the combined action of both substances.

As we are now aware, tuberculin is the concentrated fluid medium in which the tubercle bacilli have been growing. Its preparation, in short, is as follows: Tubercle-bacilli are cultivated preferably upon fluid media

to which 6 to 7 per cent. of glycerin has been added. When the culture has reached the maximum of its growth it is subjected to a degree of heat sufficient to destroy all living bacilli. It is then carefully filtered through unglazed porcelain and the filtrate is evaporated over the steam- or water-bath to the proper degree of consistency.

The statement that tubercle-bacilli have been found in tuberculin, not only in that supplied by Koch, but also in samples from other sources, is perfectly true; but the impression that this statement, stopping where it does, is likely to make upon the minds of those unacquainted with the method of preparing this agent, is by no means in accord with the true state of affairs. The method of preparation of tuberculin, as we have seen, insures the death of all living tubercle-bacilli from which it is extracted by subjecting them during the process to a degree of heat for a length of time quite sufficient to render them inert, in so far as their power to produce tuberculosis is concerned. For this reason it is by no means essential to the safe employment of tuberculin as a diagnostic agent that the fluid be deprived of all these dead and inactive organisms. The only undesirable results that might, and indeed would be very apt to occur, are purely local results—results finding expression in slight suppurative processes at the point in the tissues at which the dead bacilli accidentally present in the tuberculin are deposited. Koch, Prudden and Hodenpyl, Weil, Maffucci, Wissokowicz, and others, in their published accounts of experiments with this agent, all call attention to the local suppurations that sometimes occur at the point of inoculation, due, most likely, to the pus-producing properties of the proteid substances composing the bodies of the dead bacteria themselves—a process, however, that is in no way connected with general tuberculosis, and is of itself not of a dangerous nature.

As to the danger of using the milk of cattle that have been inoculated with tuberculin as a means of diagnosticating tuberculosis which is so slightly advanced as not to be recognized by any other means, I think there can be but little fear, and still less from its employment in non-tuberculous animals. This, however, is not the case with the milk of cattle in which the disease is more or less advanced, as has been pointed out by a number of observers, particularly Bang, Tschucca, and Ernst. In these cases there is not only danger in the immediate use of the milk, but, by keeping, this danger is increased, because, as has been observed, the bacilli not only retain their life properties, but actively increase and multiply in the milk in which they are located, retaining all the while their disease-producing peculiarities. In a series of experiments performed by me, and published two years ago in the *Johns Hopkins Hospital Bulletin*, I showed clearly that milk, as it comes from the shops, is an excellent medium upon which to cultivate these organisms. From our present knowledge on this subject, there is doubtless a greater amount of infection through this agent than is ordinarily supposed, particularly in the case of children, who depend so largely upon milk as an article of food. Indeed, several cases of apparently direct infection from the use of milk of tuberculous cattle as food for infants have been published. Where no rigorous control of dairies supplying milk to the market exists, the only safeguard possessed by the public against possible infection through this medium is the protection afforded by sterilization of the milk employed, either by boiling or through the employment of steam-sterilizers.

In regard to butter and cheese, it has been shown by investigations conducted at the Imperial Health Bureau, of Berlin, that tubercle-bacilli may and do retain their vitality in these substances frequently for weeks.

SOCIETY PROCEEDINGS.

BUFFALO CLINICAL SOCIETY.

Meeting, March 12, 1892.

DR. MYNTER read a paper on "The Treatment of Coxalgia," illustrated by cases. He considered one point in particular, namely, operation. He described the pathology of the trouble as follows: A local tuberculosis develops in the neck of the bone, with subsequent perforation into the joint and resultant coxitis. Because in resections performed at a late stage, inflammation of joints is usually found, it was supposed that the disturbance originated in the joint; but this is not the case. The synovitis and arthritis are usually results of the primary process in the bone. The inflammation may extend downward and cause a chronic osteomyelitis.

In treatment orthopedic surgeons attempt by extension to overcome the contraction. The contraction but indicates that the local disease has perforated the joint. Extension prevents the degeneration of the muscles, but it is only a symptomatic procedure, and not directed against the cause of the disease. In early cases, when good hygienic surroundings can be provided, it is well to wait a short time, to see if recovery will spontaneously take place; but such a result is only to be anticipated under the most fortuitous circumstances.

The injection of iodoform into a coxalgic joint is also but another symptomatic method of treatment. It will do little good unless the starting-point of the disease is found and radically treated.

When tuberculosis is found in a gland or in bones elsewhere, the surgeon endeavors to remove the disease by enucleation or curetting. Why should not the same principle be applied in the treatment of hip-disease? The point may be illustrated by a case: A patient is ill for two or three weeks, with tenderness and swelling around the neck of femur, showing that a local process is going on. A long incision is made down to the bone, exposing its anterior surface; then, by flexing the thigh, the whole lower portion of the neck of the bone can be plainly seen. A tuberculous abscess is found, its contents evacuated, and the wound is closed. Two weeks later sudden pain appears at hip, which seems to indicate perforation of the joint. Resection is performed two weeks later. The joint appears healthy; but on splitting the head and neck of the femur the diseased process becomes manifest, as seen in the specimen exhibited.

Amputation in hip-disease usually becomes necessary when a chronic osteomyelitis attacking the shaft of the bone has occurred. In one case of resection the bone

was diseased in its entire medulla down to the condyles. With a long spoon the canal was scraped from above downward, and a drain of iodoform gauze inserted. All symptoms disappeared, and the patient is on the highway to recovery.

It is thus seen that such cases can be treated without amputation.

Is it proper to treat symptoms for six years by means of splints, extension, etc., and leave the disease pursue its own course? Dr. Mynter stated that he had performed twelve resections in the preceding two years, with two deaths—one from intercurrent scarlatina; in all of the others perfect joints and free motion had resulted. Two of the cases were presented in apparent perfect health. Six had been shown on previous occasions.

In the discussion, Dr. Tremaine said that each case is a law unto itself. There are two schools in regard to the pathology of hip-joint disease. One believes in the strumous habit or diathesis, and assigns to trauma the exciting influence. The other school claims that tuberculosis is the sole cause. For every germ a certain soil is necessary, upon which it will more readily develop. Such a soil is the scrofulous or strumous habit. It is claimed by some that in many cases tubercle-bacilli are not found.

In the majority of cases an ostitis is present. It seems the rule that the process is an ostitis in the head of the bone, produced by trauma in a person of strumous habit.

In treatment, extension affords physiologic rest, so necessary in the rational treatment of all inflammation. It also serves to keep or pull the articular surfaces from each other; its purpose is not only the prevention of contractions.

In a large number of cases cures have been effected by extension, when applied early.

It is difficult to tell at the outset whether the disease be due to tuberculosis, to synovitis, or to ostitis; and it is best to give the patient the benefit of the doubt, using rest and extension; and when necrosis occurs, then resection, but only in young subjects.

Dr. Roswell Park stated that hip-joint disease (coxalgia) is always essentially tuberculous. Chronic synovitis is not coxitis, nor does it produce the same early symptoms, so characteristic of tuberculous disease.

Tuberculosis is a degenerative and destructive process. The other affections of the joint are regenerative, causing, like tuberculosis, deformities, but of a different nature.

Primary synovitis is rare, occurring probably in one case of ten. The diathesis itself is a most important diagnostic symptom.

In treatment, extension, preferably called traction, is now the recognized practice the world over. In a healthy joint the atmospheric pressure is very great, from fifty to sixty pounds being necessary to overcome it, hence the usual traction will do little to separate the surfaces; but when ligaments are worn and diseased, then traction is too late and resection is necessary.

The only object, therefore, that extension can have is to produce physiologic rest; and in the early stages of the disease it has yielded good results, although the advocates of the system are satisfied and speak of cure when ankylosis has been obtained. This is but substituting one evil for another; it is not cure.

Resection followed by a movable joint is far more to be preferred. Reports of cases are not necessary to fortify Dr. Mynter's position; the specimens of bones shown, split open, with the diseased process plainly visible, are quite sufficient. When several joints are affected, one after the other, they should be treated successively. In one case, in which resection of shoulder-joint, hip-joint, and elbow-joint was performed, and the shafts of one or two other bones were scraped, the patient recovered, whereas the result would, no doubt, have been otherwise had this heroic treatment not been carried out.

Dr. Heath stated that the treatment often depends largely on the social position of the patient, his environment, etc. Many cases get well without operation. Ankylosis is not cure, but as a result it is as good as the shortening that follows resection.

In closing the discussion, Dr. Mynter expressed the belief that when traction was exerted, the knee-joint in time became affected, becoming relaxed and unsteady. In one case of multiple joint-disease, the right knee-joint was first resected, then two months later the left hip. The patient died of scarlatina.

Trauma is often the primary cause. Resection is at once performed in every case. Dr. Mynter had had only one case under his care in which a cure was obtained by traction, and this case was probably not one of hip-disease. Physiologic rest is no doubt proper at first; but when decided febrile symptoms, crepitus, and tenderness around the neck of the bone appear, then operation is indicated. The process will extend unless so treated. Abscess is often a symptom; it is usually extra-articular, being situated in the head of the bone or in the trochanter. When the tissues have been divided, the abscess should be followed up to see if it communicates with the joint. Amputation has been performed when resection would no doubt have sufficed.

White, of Manchester, states that in 100 cases he had a mortality of 3 per cent., and the results were far better than ankylosis.

Under orthopedic measures from 10 to 15 per cent. die of tuberculosis of other organs. This is not the case after resections.

Cure is usually obtained in three months. It is a good rule first to try the anterior incision, and if the joint is affected, then resection should be performed.

OBITUARY.

DR. D. HAYES AGNEW.

Dr. D. Hayes Agnew died at his residence in Philadelphia on March 22d, after a brief illness. Dr. Agnew was born in Lancaster County, Penna., in 1818. He received his preliminary education principally at Moscow University, at Jefferson College, Canonsberg, Penna., and at Newark, Delaware. His medical training was obtained at the University of Pennsylvania. He was graduated in 1838, and began the practice of medicine in Lancaster County. After a short time, however, he withdrew from medical practice and engaged in business, in which, however, he was not very successful. He returned to

the practice of medicine in Philadelphia about the year 1852.

During his residence in the country he continued the study of anatomy, including dissection, under all the disadvantages incurred at a distance from the natural source of anatomic material. On resuming practice in Philadelphia, he at once began to teach anatomy in what was known as the Philadelphia School of Anatomy, in Chant Street. His success here was immediate and phenomenal, and so long as he continued to teach, he drew large classes from both of the schools of medicine then in existence.

In 1854 he was chosen one of the Surgeons to the Philadelphia Hospital, where he had his first opportunity of applying to practice his wondrously accurate knowledge of anatomy. His connection with the Philadelphia Hospital was further distinguished by his originating the present Pathological Museum, of which for a time he was curator. In 1863 he was appointed Demonstrator of Anatomy and Lecturer on Clinical Surgery in the University of Pennsylvania. In 1870 he was elected Professor of Operative Surgery, and on the resignation of Dr. H. H. Smith, in the following year, he was appointed to the position of Professor of the Principles and Practice of Surgery. He continued to hold the last position, in which he made his most signal reputation, until December, 1887, when he resigned, his resignation to take effect at the close of the session of 1888–89.

Dr. Agnew was one of the Surgeons to the Pennsylvania Hospital and to the Orthopedic Hospital in 1865. He retained these positions until the demands upon his time made it impossible to hold them longer—in the case of the Pennsylvania Hospital, with a brief interval, for eighteen years; in that of the Orthopedic for a shorter time.

Although Dr. Agnew laid the foundation of his reputation as a teacher of anatomy, and prepared himself for his success as a teacher and practitioner of surgery, it was in the Chair of Surgery at the University of Pennsylvania that his reputation culminated. His lectures were characterized by lucidity and an absence of all attempt at oratorical display. The accuracy of his anatomic knowledge made the subject of operative surgery particularly simple to him, and his lectures upon this branch were most attractive and eagerly attended by students and practitioners. His ability in this direction shone forth still more brilliantly in the surgical clinic that for so many years he held every Wednesday at the University.

Dr. Agnew's writings were, in the main, short papers on practical subjects, until he wrote his great book upon *Surgery*, finished in 1878; this was the crowning act in making world-wide a reputation that was already national. His *Surgery* has been translated into the Japanese language.

His connection with the Garfield case and the modesty with which he performed the duties incident to this trying position, did much to attract the attention of the non-professional world and endear him to the nation.

Dr. Agnew continued to practise actively until a few days before his death, although for several years previously to this event he had been making an effort to withdraw from work. How difficult this was appeared on the very last day on which he was out, when the fatigue of an operation and several wearisome consultations seemed to be the immediate cause of his last illness. He had been ill earlier in the winter with influenza, and seemed not to have entirely recovered his strength, although he expressed himself to the writer only a few days before his illness as feeling unusually well, and certainly he had greatly improved in appearance of health since the 1st of February.

The secret of Dr. Agnew's success may be said to have been, first, his thorough training in anatomy; secondly, the reputation that he acquired as a teacher of anatomy; thirdly, his skill as an operator; fourthly, his unwearying industry; and fifthly and last, but not least, his personality.

Of a commanding and dignified presence, with the courage of his opinions, associated with such a modesty and utter contempt of acting for effect, he has been, at least for the last decade, one of the most conspicuous figures in the medical history of the country. Prominent, also, in his relations with medical men was the feeling of confidence that he inspired, and the certainty with which it was known that he would never betray the trust reposed in him—would always protect with his towering reputation any weaker points that the inexperience of his younger colleagues might have betrayed.

WILLIAM H. BUNCE, M.D., died in Oberlin, Ohio, February 13, 1892, where he had practised medicine from the time of his graduation. Dr. Bunce was born in Paterson, N. J., June 29, 1830. He came of ancient Scottish stock. He was married in June, 1852, to Eleanor S. Conant, who, with two daughters and one son (Dr. Wm. C. Bunce), survives him. Dr. Bunce was a Surgeon, with rank of Major, during the war; and was connected with a number of medical societies, in which he had at various times held prominent positions. He has been known as one of the leading surgeons of Northern Ohio. There was a peculiar gentleness in his ministrations to those that came under his care, which made them feel that he was not only their physician, but also their friend. It may be well said that by his skill and worth he has built a monument that will live after him, in the hearts of those that learned to love him.

NEWS ITEM.

Sixth Annual State Sanitary Convention of Pennsylvania.—The State Board of Health of Pennsylvania will hold the Sixth Annual State Sanitary Convention in the city of Erie. A hearty invitation is extended to all persons in any way interested in sanitary matters to visit Erie upon this occasion. The Convention will be held March 29, 30, and 31, 1892. It will be called to order on the 29th, and end on the afternoon of the 31st. Commutation rates can be obtained by writing to DR. WILLIAM B. ATKINSON, Medical Inspector, 1400 Pine Street, Philadelphia, Pa.

ORIGINAL ARTICLES.

EHRLICH'S TEST OF THE URINE IN TYPHOID FEVER.[1]

BY ARTHUR R. EDWARDS, A.M., M.D.,
RESIDENT STAFF, COOK COUNTY HOSPITAL, CHICAGO.

IN 1882 Ehrlich announced the discovery of a reaction that he claimed to be characteristic of the urine of typhoid fever. Sulphanilic acid, an amido-derivative of the benzine group, when treated with nascent nitrous acid, forms diazo-benzene-sulphonic acid, which is decomposed with facility, and exhibits the greatest affinity for aromatic and other compounds. The significance of Ehrlich's reaction has been variously estimated, some extolling it as an important, or even pathognomonic, feature of typhoid fever, while others regard the reaction as empirical, unreliable, and unscientific.

Rütimeyer, in 260 cases, found the reaction lacking in health, hysteria, myelitis, specific hepatitis, diabetes, pyelonephritis, jaundice, cholelithiasis, surgical affections, and non-malignant ovarian cystomas. It is occasionally found in esophageal and gastric carcinoma, serous pleurisy, chronic nephritis, tuberculous meningitis, cardiac failure, caries, old abscesses, pyemia, and scarlatina, and still more frequently is it present in croupous pneunonia, pulmonary actinomycosis, carcinoma, sarcoma, and tubercles of the peritoneum.

The author quoted regards the reaction as diagnostic, always absent in febrile catarrhs, and diagnostically second only to the eruption and splenic tumor. If not found in the first and second weeks, the affection is not typhoid, or is of the mildest form. It sustains no relation to the course of the fever, is not influenced by medication, and is found morning and evening. Its intensity bears no relation to the prognosis, and it is apt to occur in relapses.

Bacnacci believes the test bears some relation to sugar and acetone, and states that iodol, sozoiodol, thymol, and strychnine, will produce the reaction. He asserts that it is usually absent from typhus, variola, pneumonia, and acute enteritis.

Simon found it in typhoid fever and tuberculosis alone, and in four only of twenty-six cases of typhoid was it absent.

Taylor asserts that the reaction is wanting in acute general tuberculosis, lobular and lobar pneumonia; that it occurs in measles, but seldom in rheumatism, exceptionally in the healthy, in a few cases of acute and chronic pulmonary tuberculosis, and with more than average frequency in the albuminous urine of acute and chronic nephritis.

With the intention of ascertaining, if possible, the precise value of the test, the writer undertook a series of 600 urinalyses, covering a period of ten weeks, and embracing 275 medical and surgical cases. The method chiefly employed was the following: Two solutions are kept in separate bottles. One contains 5 c.c. of hydrochloric acid, with sufficient water to make 1000 c.c., and is saturated with sulphanilic acid. The second bottle contains a ½ per cent. solution of sodium nitrite. Forty c.c. of sulphanilic acid solution are added to 1 c.c. of the sodium nitrite, and the two thoroughly mixed. Of this mixture 1 c.c. is added to 1 c.c. of urine, and the two shaken forming a yellow solution. Drop by drop 1 c.c. of ammonium hydrate is allowed to trickle down the side of the tube to form a supernatant white layer, between which and the yellow the least shade of garnet is rendered striking by contrast. In a number of cases 1 c.c. of urine was shaken with 6 c.c. of absolute alcohol, filtered, and the filtrate treated as indicated. Only a hue between eosin and garnet was recognized, and yellow and brown rings were disregarded. Distilled water was used in the solutions, and accurate measures maintained in their preparation and use. As the reaction is very delicate, the test tubes were washed in fresh water twice after each test to eliminate contamination. The solutions were kept separate, and fresh reagents used with each analysis, since the sulphanilic and nitrous acids, when combined, decompose rapidly.

In analyzing the cases observed, we noted the clinical course of the disease, the presence or absence of the reaction, its first appearance and duration, the period of illness prior to admission, the fever, the urine (reaction, specific gravity, urea, albumin, casts, and occasionally sugar), especially the decline of the disease, relapses, whether the temperature subsided or the test faded first, the ultimate issue, and in selected cases the absolute-alcohol modification.

[1] Read before the Cook County Hospital Clinical Society, November 15, 1891.

One hundred and thirty cases of *typhoid fever* were analyzed. From two undoubted cases the reaction was absent throughout the disease, even at the fastigium, and the reaction was lacking in six in the period of defervescence. The test bears no relation to the ultimate issue, being equally brilliant in fatal and recovering cases. Only in isolated cases can we observe the first appearance of the reaction, as we rarely see the disease in its incipiency, or the patient gives unreliable information through ignorance, delirium, or imperfect understanding of English. The exact relation, therefore, of the reaction to the first stage of the disease must be more or less indeterminable, and, scientifically, the appearance must be dated solely from the admission of the patient. Relapses constitute the only exception. In sixty-three cases in which the exact date of disappearance was noted, the average life of the test was thirteen days, although in cases the reaction lingered until the forty-second and fiftieth days, as determined by repeated daily analyses. These results somewhat exceed the limits set by Simon. The reaction bore no direct ratio to the temperature, although it was most brilliant at the fastigium. The later pyrexia of typhoid fever is probably due to secondary infection, and not to the specific process. This supposition explains the usual persistence of the pyrexia after the disappearance of the reaction. It has been said that Ehrlich's test disappears when the morning temperature becomes normal. Our results do not confirm the assertion. In a few cases both disappeared together. Usually the pyrexia outlives the reaction, and in seventeen cases Ehrlich's test was obtained after all fever had disappeared, even as late as ten days after normal temperature had been established. In some cases the persistence of the reaction was attributable to coincident nephritis or tuberculosis, but in the majority these and other factors, even febrile albuminuria, had disappeared, or could not be demonstrated. Albumin was found present in thirty-five, and absent from ninety-five cases. Relapses occurred in twelve cases, and the reaction reappeared in nine of these. The duration in these varied from two to nineteen days. In three cases of typhoid the absolute alcohol test was negative.

Enteritis; Febricula. Of nineteen cases the reaction was well marked or brilliant in six. In two of the six albumin was present. The absolute alcohol test was variable, but the reaction was obtained in two cases by its use. It is important to note that the claim was made for Ehrlich's test that it differentiated between typhoid fever and enteritis and febricula. The inference from the results noted, and the fact that the reaction could not be found in two typhoidal cases, is obvious. The presence or absence of albumin may obscure the interpretation of the reaction. It is sometimes difficult to differentiate between typhus levissima and acute enteritis, and it is here that the test is most frequently unreliable.

Malaria. 1. Case of chronic malaria—inveterate spleen case. There was well-marked reaction; absolute alcohol was not employed. 2. Quotidian—lasted one week; no albumin; brilliant reaction; absent with absolute alcohol. 3. Quotidian—no albumin; brilliant reaction; no absolute alcohol test. 4 and 5. Quotidian—no albumin; reaction absent with and without absolute alcohol.

Tuberculosis. In 9 cases of acute and chronic pulmonary tuberculosis the test was brilliantly displayed, and in all but one disappeared with absolute alcohol. In 1 case of intestinal tuberculosis that entered *in extremis* the reaction was very pronounced (autopsy). Dr. F. X. Walls has very kindly given me the result of his investigations upon 22 cases other than typhoid. He found the reaction present in 6 cases of tuberculosis of the lung, pleura, intestine, and peritoneum, and absent from 1 case of pulmonary tuberculosis; also brilliant reaction in 3 cases of miliary tuberculosis (autopsies). In the following lists Dr. Walls's cases will be noted by his name in brackets. In surgical tuberculosis the reaction was well-marked in sacro-iliac tuberculosis, 2 cases; brilliant red in tuberculosis vertebrarum, 1 case; brilliant in tuberculous lumbar abscess, 1 case; moderately well developed in the third stage of tuberculous coxitis, 2 cases; absent from tuberculous coxitis, first stage, 1 case; absent from 3 cases of tuberculosis of the knee-joint several weeks after operation, and present in 2 shortly after resection.

Rheumatism. Chronic, absent from 1 case. Subacute, 6 cases; present in 3, but absent with absolute alcohol. Acute, 5 cases; present in 1. (Albumin absent from all.) Present in 33 per cent. of all cases.

Nephritis. Chronic parenchymatous, absent from 4, present in 2 (from 1 case absent with absolute alcohol). Chronic interstitial, 9 cases; present, though variable, in 6. Acute, 3 cases; brilliant in all, but absent with absolute alcohol. These are aside from cases observed in connection with any other disease. Present in 61 per cent. of all cases.

Diabetes. The fermentation test was employed to avoid the fallacy of confusing sugar with those organic acids which reduce Fehling's solution, and, according to Simon, also give Ehrlich's reaction. No albumin in either case. Ehrlich's test very brilliant in both cases, and it persisted in one with the absolute alcohol modification upon a slight rise of temperature, lasting two days, for which no cause could be ascribed.

In the large majority of the following cases either

autopsies or operative measures confirmed the diagnosis.

Carcinoma. 1. Of stomach, with secondary deposits in liver; no albumin; brilliant. 2. Of stomach, cardiac orifice; well marked; no albumin. 3. Mammary carcinoma, absent. 4. Mammary carcinoma, fairly well marked.

Syphilis. Tertiary; brilliant in 1 case. Specific periostitis, well exhibited; no albumin; present with absolute alcohol. Absent from 3 cases.

Cardiac lesions. Mitral regurgitation, brilliant with and without absolute alcohol; no albumin. Mitral lesions, no albumin; 3 cases; brilliant in 2 and absent from 1 [Walls]. Cardiac degeneration (? fatty), no albumin; brilliant, but variable. Mitral regurgitation, absent. Aortic stenosis and regurgitation with pleuro-pneumonia and acute pericarditis; no albumin; brilliant red.

Lung. (Besides tuberculous lesions.) Lobar pneumonia, 2 cases; no albumin; brilliant reaction. Absent from broncho-pneumonia and pleurisy, and from pleurisy with effusion [Walls]. Pleuro-pneumonia, 2 cases, present [Walls]. Pleuro-pneumonia with acute nephritis, brilliant [Walls].

Plumbism, 3 cases; present in 1; no albumin; absent in 2. Walls, 1 case, absent.

Cerebral hemorrhage, 3 cases; absent in 1; fairly well marked in 1; trace of albumin; brilliant in 1; no albumin.

Present in *acute septicemia,* 3 cases in which albumin and peptones were absent; most brilliant reaction.

Chronic traumatic dry arthritis of hip-joint, 2 cases; no albumin; absent in 1; present in the other with and without absolute alcohol test.

The reaction was found once each in the following: Multiple neuritis, variable (no albumin); alcoholic gastritis (no albumin); purpura hemorrhagica (much albumin); peritonsillar abscess (trace of albumin); meningitis (albumin and casts); pyosalpinx (no albumin); abscess of abdominal wall (no albumin.

Cirrhosis of liver (no albumin). Hypertrophic, 3 cases; absent in 1, present in 2, with and without absolute alcohol. Atrophic, absent with and present without absolute alcohol. Hypertrophic, absent [Walls]. *Simple jaundice,* present three times (no albumin). *Acute intestinal obstruction,* no albumin, present in 1 case. *Acute intussusception,* both with and without absolute alcohol, brilliant. *Multiple abscess* of liver, brilliant [Walls].

Absent from—9 cases of acute alcoholism; insolation, 2 cases; chronic dysentery, 1; cholelithiasis, 1; gastritis, 1; acute mania, 2; hysteria, 3; simple anemia, 7; vomiting of pregnancy, 1; echinococcus of liver, 1; thrombo-phlebitis, 1; acute suppurative osteomyelitis, 1. Absent from suppurative meningitis, 1 case [Walls].

The two following cases would indicate how invaluable Ehrlich's test would be if it were confined to one affection or to fewer diseases than it is. The test was absent from perityphlitic abscess in which the symptoms closely simulated typhoid, the patient having anorexia, nausea and emesis, frontal headache, cough, tâche cerebrale, tympanites—characteristic temperature, tenderness, and pain, with gurgling in the right inguinal region and papular eruption almost lenticular in character. A diagnosis of appendicitis was made upon an induration over the ileo-cecal valve, and the absence of Ehrlich's test had some weight in excluding typhoid. Operation confirmed the diagnosis. Dr. Walls related a case in which a diagnosis of mania was made by a nerve specialist. A brilliant Ehrlich reaction puzzled the house physicians, who placed considerable reliance on the test. Post-mortem examination revealed a typical stage of typhoid, although there were no ante-mortem evidences of typhoid save the sulphanilic acid indication.

The indications from the foregoing analyses are formulated as follows:

1. The reaction is independent of any single disease or any group of diseases.

2. It is frequently found in urine containing albumin, peptone, biliary substances, sugar, aromatics, and possibly leucomaïnes or ptomaïnes.

3. We have failed to obtain more constant results with the absolute alcohol than without its use.

4. Ehrlich's test is not always present in typhoid, even at the acme of the disease; it was absent in 1½ per cent. of our cases. The reaction, therefore, is at best only a presumptive, and not a positive, evidence of typhoid. Its value is on a par with that of gurgling and tenderness in the right inguinal region and inferior to the temperature, roseolæ, and splenic tumor.

5. Together with more reliable signs and symptoms, as temperature, enlarged spleen, etc., it may contribute to a diagnosis of typhoid, and conversely, when absent, in 98½ cases out of 100, the disease is other than typhoid.

6. It is found in many other diseases, some of which, in certain clinical features, may simulate typhoid—*e.g.*, septicemia, uremia, tuberculosis in its varied aspects, intestinal, peritoneal, miliary, etc., as well as enteritis, malaria, and pneumonia. In differential diagnosis, therefore, when other distinctive symptoms are lacking, the sulphanilic acid test is untrustworthy. It fails when most keenly wanted, and may be absent in otherwise typical typhoid fever.

7. If much reliance is placed in the test, a typhoid relapse may be confounded with complications. We have observed, as complications and early sequelæ yielding the reaction, acute nephritis, lobar pneu-

monia, pulmonary tuberculosis, pleurisy, etc., and would have been at a loss as to the cause if confidence had been reposed in the test.

8. Inasmuch as it occurs typically in many diseases in which the causes and elaborated products differ, and since the various compounds with which the diazo-benzene-sulphonic acid unites are as yet unknown, the reaction cannot commend itself to the scientific chemist, however it may be regarded clinically.

FORMS OF PSEUDO-TABES DUE TO LEAD, ALCOHOL, DIPHTHERIA, ETC.[1]

BY JAMES HENDRIE LLOYD, M.D.,
PHYSICIAN TO THE NERVOUS AND INSANE DEPARTMENT OF THE PHILADELPHIA HOSPITAL, TO THE METHODIST EPISCOPAL HOSPITAL, AND TO THE HOME FOR CRIPPLED CHILDREN.

LOCOMOTOR ataxia is one of the best-known diseases. Its classic array of symptoms, so familiar to all, occurs, as a rule, with a precision of type and regularity of sequence that admit of but few errors in diagnosis. Its history and course have been written so frequently and so well that little remains to be said; while, unfortunately, its prognosis admits of but such a frank statement of despair, that it has long been described as one of the most inveterate and progressive of diseases. Locomotor ataxia, however, like many other diseases, has its counterfeits. All is not necessarily lost, as was once taught, to all men who stagger in the dark, whose knee-jerks are abolished, and who have pain and numbness in the legs. These counterfeits, doubtless, are in the minority to the true ataxics, but that they are more prevalent than was formerly supposed is at least probable; and that it is highly important for the welfare of the patient and the credit of the physician to differentiate them, is apparent. This paper will discuss especially the etiology and diagnosis of these forms of pseudo-tabes, and will be based largely upon personal observation.

In 1884 Dejerine[2] described a disease which he called *nervo-tabes peripherique*, and gave the clinical histories and autopsies of two patients whose disease he had diagnosticated in life as locomotor ataxia. Both of these patients presented incoördination, anesthesia, abolition of knee-jerks, slight atrophy, and paresis, without eye or bladder symptoms. They had used alcohol to excess. The autopsies revealed pronounced inflammation of the cutaneous nerve-endings, slighter changes in the intramuscular nerves, and no change whatever in the spinal cord, nerve-roots, or ganglia. Dejerine had not found any analogous cases reported at that time in medical literature, and deserves credit for first demonstrating the striking resemblance of these obscure cases to locomotor ataxia. At about the same time, however, Dreschfeld[1] described a type of alcoholic ataxia characterized by incoördination in the gait, absence of knee-jerks, with lancinating pains, but without atrophy or paralysis. His clinical picture was strikingly like that of Dejerine, but was not supplemented by the same careful post-mortem findings. In the same year Krüche wrote a paper on "Pseudo-Tabes in Alcoholics."[2] But earlier than all of these, Samuel Wilks, in his lectures in 1878, described the drunkard's paraplegia, and said that in some cases it closely resembled locomotor ataxia. Wilks believed that the lesion was in the spinal cord, but he wrote before multiple neuritis was much more than dreamed of.

Still earlier (1867) Leudet[3] wrote an elaborate paper on chronic alcoholism in which he described the same combination of symptoms—anesthesia, hyperesthesia, disordered gait, and paresis—and in fact came near to describing what we recognize to-day as polyneuritis. In recent years the literature of multiple neuritis has grown to a vast extent. It has become, therefore, more and more necessary to differentiate the various types of the disease and to recognize its many causes. With this motive, Leyden in 1888 wrote a monograph in which he distinguished five forms, one of which he named the sensory form, under which heading he grouped the acute ataxics, and borrowed for them, from the earlier paper of Dejerine, the title of *neuro-tabes peripherica*.

It may be said in general terms that all of these cases of pseudo-tabes or acute ataxia are instances of a multiple neuritis of this sensory form of Leyden, and that most of them have probably a morbid anatomy similar to or identical with that demonstrated by Dejerine, *i. e.*, an involvement especially of the peripheral distribution of the cutaneous nerves. Hence the most common symptoms in these cases are disorders of sensation, especially anesthesia and paresthesia, with ataxia and abolition of the knee-jerk. To these must be added symptoms, in varying intensity, of involvement of the motor nerves, never perhaps quite absent, but often requiring careful and expert examination for their detection. From these ataxic cases all degrees of severity occur up to well-recognized cases of multiple neuritis, with general involvement of the sensory and motor nerves. The eye and bladder are seldom involved in these ataxic cases, but important exceptions occur. Of the great viscera, the heart and kidneys are most likely to suffer.

In some cases it is quite impossible at once to arrive at a correct diagnosis. In doubtful cases the history alone may determine the diagnosis; and this history, with certain attendant phenomena—as, for instance, the blue line on the gums in lead cases, tachycardia in alcoholic cases, and paralysis of accommodation in post-diphtheritic cases—should always be most carefully investigated. In my observation by far the most frequent causes are alcohol, lead, and diphtheria. Others report arsenic, and such infectious processes as variola, typhoid fever, tuberculosis, and syphilis; also wasting diseases, as diarrhea and dysentery. Bartholow has reported cases of paralysis following bowel-disorder, which were probably examples of neuritis. Syphilis is now believed by many to be capable of causing neuritis; indeed, it may be a question whether some cases of so-called syphilitic locomotor ataxia, cured by mercury and iodides, have not been cases of peripheral neuritis. Dejerine, in another paper, described the onset of a fatal multiple neuritis in a morphine-taker; and I have myself seen amblyopia accompanied by anesthesia of the feet and legs in an excessive smoker.

The eye-symptoms are the most reliable for purposes of differentiation. None of the forms of multiple neuritis, except the post-diphtheritic kind, present, as a rule, any affection of the internal or external ocular muscles. I have looked for them always in vain in alcoholic and lead cases. In diphtheritic paralysis, however, the ciliary muscle is often paralyzed, while the light-reflex remains—the very opposite to the Argyll-Robertson pupil seen in locomotor ataxia. At the same, time there is likely to be paralysis of some of the external ocular muscles, causing strabismus; almost always associated with paralysis of the velum palati. In lead-poisoning optic neuritis is sometimes observed.

The functions of the bladder and sexual apparatus are not often affected in any form of polyneuritis, especially the ataxic form. The only case in which I have seen impairment of the bladder was in a woman with grave alcoholic paralysis, with mental symptoms, and weak, rapid heart. The involuntary passage of urine in her case was the result of her mental condition. In chronic inebriates the sexual appetite rather than the sexual power is impaired. On the other hand, locomotor ataxia, as is well known, is very likely to exhibit soon in the case impairment of sexual power and of the expulsive power of the bladder.

It is most probable that ataxia or incoördination, whether in true tabes dorsalis or in pseudo-tabes, is caused by the impairment of sensation. However caused, it is very similar in the two conditions. We have at present in the Philadelphia Hospital a man suffering with a severe grade of multiple neuritis, with wasting of the muscles of the extremities. He has an alcoholic history, although, strange to say, his disease developed rapidly after a sunstroke. This man has diminished and sluggish, not abolished, knee-jerks. His gait is typically ataxic, with elevation and flapping of the feet. He cannot stand an instant with his eyes closed; in fact, he has such a condition of *astasia* that he is sometimes compelled to keep walking to avoid falling. His eyes are normal. It has been claimed by some that the element of muscular weakness, in cases of neuritis, admits of a distinction being made between the ataxia of the two conditions, as in multiple neuritis the ataxic movement is evidently more feeble than in tabes dorsalis, and the foot is lifted higher because of the paralysis of the extensors. But in the cases of pseudo-tabes, this muscular weakness is often not conspicuous, and hence this distinction is not possible. I have recently put side by side a case of acute lead-poisoning and a typical case of locomotor ataxia for the purpose of comparing the ataxic movements in the arms, which are very marked in both cases.

The cases are as follows:

Male, aged thirty-eight years. After four months' exposure in a lead factory he began to have colic, constipation, vertigo, and headache. He then had several convulsions, and passed into a state of lead encephalopathy, from which he is now recovering. He has no paralysis of the extensors, but the shoulder muscles and biceps are paretic. He has some patches of anesthesia on the arms, hands, and legs. His walk is ataxic, and the movements of his arms markedly so. He has the blue line on the gums, no albumin or casts in the urine, and the margins of the optic discs are slightly clouded.

This man's case has been a grave one, and admits of no confusion. The ataxic movements of his arms, however, are almost identical with those of the second case, as follows:

Male, aged thirty-eight years. He may be called a case of rapid acute locomotor ataxia. The disease began with numbness and pricking sensations. The patient was soon suffering with fulgurant pains; then ataxia, with inability to walk in the dark. The arms are involved as well as the legs. The knee-jerks are abolished. For a year he has had nocturnal incontinence of urine, and when the bowels are overloaded, some paresis of the sphincter ani. The pupils are unequal and do not respond to light. There are irregular discs, with contracted arteries. There is apparently some latent iritis, and there is a posterior synechia. The man has had syphilis.

The ataxic movements in these two men are so similar as to attract attention, the only difference being that the man with lead-poisoning takes longer to perform a given action than the tabetic, probably because of the element of muscular atrophy in his case.

Motor symptoms, other than ataxia, are not conspicuous in cases simulating tabes; in fact it is the absence of marked paralysis in these cases of multiple neuritis that more than anything causes them to resemble cases of true locomotor ataxia. This was so in Dejerine's cases already referred to, in which the autopsies showed the principal changes to be in the cutaneous nerves. These are the cases which Leyden classes as his sensory forms, and calls acute ataxics. They are more often alcoholic and diphtheritic cases than any others. It is most probable, however, that none of these cases are entirely exempt from paresis in some muscles. Careful examination usually reveals some loss in muscular masses, and electrical tests sometimes solve a doubt. Paralysis may be slight, especially in the large muscles of the limbs, and may not be conspicuous when the patient is lying down, but when standing up or when executing fine movements with the fingers and toes the motor impairment is more marked.

I recall the case of a man in middle life who had diphtheritic ataxia, with anesthesia, but who had so little paralysis that he was able to be about without attracting attention. Such cases in middle life are especially likely to be diagnosticated as cases of locomotor ataxia.

In diphtheritic cases, acute sensory symptoms, such as pain on pressure over nerve-trunks and on handling the limbs, are not nearly so marked as in alcoholic cases. In all cases, however, presenting true ataxia from whatever cause, I believe a diminution or alteration of sensory function can be demonstrated by careful examination.

Rapidity of evolution is not an absolutely sure sign that the disease is multiple neuritis, because true tabes may evolve rapidly. I have under observation a case of apparently true tabes in a ship-carpenter which began and continued as follows:

Two years since, while crossing the equator, being much overheated, he took a shower-bath, by having buckets of water thrown over him. He was in good health at the time. Three hours later he began to have tingling sensations in the extremities, which he says were at first confined to one side. In a few days he was paralyzed. Later, the other side was affected, but never so badly as the right side. At present he presents a very ataxic gait, pains in the legs and back, and abolition of the knee-jerks. One pupil is twice as large as the other, the dilated iris being immobile, and the other showing the Argyll-Robertson phenomenon. He cannot stand with his eyes shut. His control of his bladder and rectum is impaired, and one ankle is enlarged somewhat like a tabetic joint. The muscular nutrition in the arms and legs is not bad, and his grip in each hand registers 80°. The man has had destructive nose-disease, but denies syphilis.

This patient's history suggests neuritis, but his present state is so exactly that of locomotor ataxia, with eye and bladder symptoms, that the conclusion is almost forced that such is the correct diagnosis.

The case of the patient from whose cord and nerves I present sections, has interest because the diagnosis of locomotor ataxia was actually made by a very expert clinician.

I. L., aged fifty-eight years, was a painter by trade. He had been exposed to lead for thirty years. He had a very clear history of many attacks of colic, constant constipation, and several attacks of wrist-drop. He had also the blue line on the gums, and that frequent result of chronic plumbism, a contracted kidney, as shown by casts, albumin, and the specific gravity of his urine. No lead could be detected in his urine. He had been an excessive drinker, but had never had syphilis. The diagnosis with which he was sent to me had been made largely upon the ataxic gait, swaying with closed eyes, abolition of the patellar reflexes and numbness, tingling and retarded sensation in the soles. I found his real condition as follows: In addition to the foregoing very evident symptoms, he had well-marked paresis and atrophy of both the extensors and flexors of the forearms and hands, as well as the biceps and deltoid muscles. On voluntary motion there was tremor rather than ataxia of the arms and hands. There were paresthesia and areas of anesthesia on the hands, legs, and soles of the feet. The legs and arms were slightly contractured. The external and internal eye-muscles were normal. Sexual power was normal, and the control of the bladder was perfect. The gait was ataxic, but flapping of the feet was not marked. The hands and feet were slightly edematous. There were partial reaction of degeneration and abolition of faradic contractility in all of the paretic muscles. Optic atrophy was noted by Dr. Gould—no doubt the result of optic neuritis due to lead. The diagnosis was chronic lead-poisoning, with multiple neuritis and contracted kidneys. The patient died in a few weeks in uremic coma. The sections show quite extensive inflammation, or degeneration due to inflammation, in the several nerve-trunks examined, with involvement, rather diffused, of some areas of the cord, notably in the lumbar region. The systemic changes of locomotor ataxia are not present.

In studying this case, in which it seems probable that the cord was involved later than the nerves, I have been reminded of the suggestion made by Leyden, that true tabes dorsalis may be secondary to peripheral neuritis of the sensory or cutaneous form. This is still further demonstrated in a recent study by Pal,[1] who, in a series of cases of multiple neuritis due to alcohol, arsenic, typhoid infection, etc., found apparently secondary changes in the posterior columns and other parts of the cord. It is also well to recall that locomotor ataxia is sometimes complicated by an attack of acute multiple neuritis.

VIBURNUM PRUNIFOLIUM: ITS PHYSIOLOGIC ACTION AND THERAPEUTIC APPLICATIONS.

By R. L. PAYNE, Jr., M.D.,

EXAMINER IN PHYSIOLOGY, NORTH CAROLINA BOARD OF MEDICAL EXAMINERS, LEXINGTON, N. C.

To those physicians who, like myself, are engaged in rural practice, anything throwing light on indigenous remedies is always welcome, not only because the remedy is easily procured, but because to the lot of us all falls a large share of patients who, from inability or unwillingness, fail to pay their bills. A native remedy, therefore, that enables us to lessen our drug-account and set at defiance the manufacturing pharmacist will always prove a desideratum. Such a remedy is found in the viburnum prunifolium, or black haw, and after fully testing its merits I have learned to rely upon it as deserving of much confidence when judiciously prescribed.

The viburnum is not a new remedy, but one the virtues of which I believe to be but poorly understood. It was first described by Dr. Phares, of Mississippi, in 1866, as a "nervine, anti-spasmodic, tonic, astringent, and diuretic," but he especially recommended it as a remedy in threatened abortion. His article, though eliciting much temporary interest, was soon forgotten by the mass of the profession until the remedy was rescued from oblivion by the distinguished Dr. Jenks, of Detroit, who, in 1876, read an article before the American Society of Gynecology endorsing the claims made for haw by Dr. Phares, and extolling its virtues in abortion, the nervous diseases of pregnancy, and declaring it to be "serviceable in all uterine disorders characterized by loss of blood." This last statement of Dr. Jenks is fallacious, since it is apparent that as the causes of uterine hemorrhage are various, no one remedy, unless it be astringent—and this can only be claimed for haw in a slight degree—could prove useful in all cases.

Since the publication of Dr. Jenks's article the remedy has been used by a number of physicians, and isolated reports have at various times appeared in current medical literature setting forth the value of haw in threatened abortion, menorrhagia, metrorrhagia, dysmenorrhea, the vomiting of pregnancy, stomatitis materna, etc. The remedy has been described as stimulant and sedative, mildly oxytocic and anodyne, and indeed the *United States Dispensatory*, edition of 1886, declares that while haw has been claimed to possess medicinal attributes, "its virtues must be considered apocryphal." From this mass of conflicting testimony it is impossible to determine the true value of the drug, and therefore the writer has instituted an experimental research as to its effect upon cold-blooded and warm-blooded animals,[1] from which are deduced the following conclusions:

First. Black haw, so far as these experiments indicate, exerts no influence on consciousness or sensibility.

Second. The most constant and marked effect of viburnum is upon the centers of motion. After its administration there follow paresis, paralysis of voluntary motion, and finally complete loss of all reflex power, the extent of this loss being governed by the dose administered. A first effect is paresis, which makes its appearance not suddenly, but as a gradually growing weakness; then there follows marked incoördination of muscular movement, and whatever motion is attempted is of a jerky, spasmodic character; then, the effect being pushed, there occurs, almost suddenly, complete loss of voluntary movement; and later, in fatal cases of poisoning from this drug, all reflex power is lost some time before cessation of the heart's action or of the respiration. In cold-blooded animals the pupils contract under the influence of haw, but in warm-blooded animals no effect on the pupils was noticeable. Muscular irritability is lost after lethal doses of haw, but the ability of the nerves to transmit the electric current is lost before muscular contractility.

Third. The effect of viburnum on motion, as previously described, must be due to the action of the remedy on the motor centers of the spinal cord. The fact that incoördinate movement precedes complete loss of motor power, argues that haw has some selective action on the posterior columns of the cord. The effect of haw upon the cord seems to be to hold in abeyance rather than to destroy its motor functions, since after all motor power is lost following its administration, electricity applied to the cord causes motion in the parts below, and applied directly to the nerve-trunks causes more active movement. A peculiar, spasmodic, chewing motion of the jaws was observed in some of the experiments on rabbits, and would indicate a specific action, difficult of explanation, on the seventh pair of nerves. The functions of the cerebrum, as manifested in the persistence of consciousness and the sense of pain, show that viburnum exerts at least no primary action upon the brain.

Fourth. A constant and first effect of haw is to paralyze the vasomotor nerves, with consequent dilatation of the bloodvessels; the capillaries of the rabbit's ears become distended with blood. At the same time, in warm-blooded animals, the action of the heart becomes very rapid and feeble, and, later on, the vessels of the periphery become so small that even large vessels in the ear of the rabbit are

[1] These experiments are given in detail in the Transactions of the North Carolina Medical Society, 1888.

almost unapparent to the eye. Coincidently the surface-temperature falls very low. The diminution in the size of the vessels seems attributable to diminished volume of the circulating fluid, and not to contraction of the muscular walls of the vessels through increased vigor.

In cold-blooded animals the action of haw on the heart differs somewhat from its effect upon warm-blooded animals. Instead of growing more rapid, the heart becomes gradually slower and slower, but the similarity of action is marked in the disturbed rhythm and constantly increased feebleness of the heart's pulsations. In one of the experiments the normal action of the rabbit's heart raised the column of mercury in the manometer connected with the carotid artery fully five inches, but when the animal was fully under the influence of the medicament the pressure fell so low as to exert no influence on the mercury: while a comparison of the blood-pressure taken with a mercurial kymograph from the carotid of rabbits before the administration of the haw and after the animals come fully under its influence, show conclusively the fall of the blood-pressure under the action of the drug. In both warm-blooded and cold-blooded animals, after lethal doses of haw, paralysis of the heart precedes cessation of the respiration. Post-mortem investigation shows the right ventricle and vena cavæ distended with soft coagula, and the left ventricle also contains some soft clots; the lungs are congested, and all the post-mortem indications are that the heart is arrested in diastole from paralysis of its vasomotor ganglia.

From the foregoing summary it seems evident that viburnum paralyzes both the centers of voluntary motion and the reflex functions of the spinal cord.

From this knowledge of the physiologic action of haw we naturally conclude it is destined to become an approved remedy in all diseases characterized by increased excitability of the motor centers. An especial recommendation for viburnum in these cases is that it paralyzes the motor centers without impairing sensation or consciousness.

In the convulsions of hysteria, whether involuntary or artificially induced, in hystero-epilepsy, in *petit mal*, in the true epileptic seizure, and in various localized spasmodic troubles, we may expect much good from haw in the prevention of recurring paroxysms.

In cases of paralysis agitans the writer has witnessed marked diminution in the tremor, and has added much to the comfort of the patient by the prolonged use of moderate doses of this remedy. In idiopathic dysmenorrhea (?)—by which term I prefer to designate all painful menstruation unaccompanied by organic lesion or displacement—haw is exceedingly useful. This form of dysmenorrhea is most frequent in subjects of the hysterical temperament, or in women in whom, either by reason of faulty development or the neglect of hygienic laws, the nervous system has become predominant. Idiopathic dysmenorrhea is characterized not only by the absence of organic defect, but also by acuteness of pain as well as by irregularity, the suffering being much worse during some periods than in others; the condition is by some teachers designated ovarian, by others spasmodic dysmenorrhea. In this form of painful menstruation the viburnum will prove of the greatest utility if it be administered for a few days prior to and during the time of the menstrual epoch; and even in painful menstruation due to obstruction, while we could not expect this agent to prove curative, it will certainly lessen the violence and frequency of the colicky, bearing-down pains, and is open to none of the objections that apply to the use of opiates.

In this connection it may not be out of place to refer to the statement of Dr. Edward Jenks, who declares that haw is only useful in those cases of dysmenorrhea associated with menorrhagia. This statement, in the writer's opinion, is not absolutely correct, but there certainly are cases of dysmenorrhea associated with menorrhagia in which ovarian influences play a potent part as etiologic factors in the production both of the increased and painful flow that are much benefited by the viburnum.

That there is a form of dysmenorrhea produced by ovarian influences is beyond question. Ovarian irritation is common at the age of puberty; is frequent in sterile marriages; is often caused by sexual excesses, and is common among prostitutes or when great disparity exists between the ages of husband and wife; and, lastly, like the final flickerings of the candle burned into the socket, ovarian irritation is one of the most constant phenomena of the menopause, and whenever found associated with menorrhagia we can safely regard it as one of the causes of the increased flow, and may confidently expect to do much for its relief by the administration of the viburnum. On the other hand, in menorrhagia due to congestion of the portal circulation, subinvolution of the uterus, metritis, lacerations and erosions of the cervix, and when fibroid tumors exist, haw not only exerts no beneficial effect, but may prove positively injurious.

In the prevention of abortion haw has proved itself preëminently useful, and with a clear knowledge of its physiologic action it stands upon a firm basis before the profession as the very best agent known for the purpose named. Labor, whether at full term or occurring prematurely, is nothing more or less than a reflex action, and haw, from its power to lower the irritability of the motor centers through

all grades of debility, from the slightest paresis to the most profound paralysis, commends itself above all others as the remedy in threatened abortion.

Of course, if the ovum is detached from its uterine connections, in part or entirely, we could not expect, nor would we desire, its retention, but in cases the result of emotional causes, or of other causes acting exclusively through a nervous agency, when there are simple expulsive pains without much hemorrhage, even though there may have already resulted considerable dilatation of the os uteri, the viburnum will almost surely prevent abortion if it be faithfully pushed. Viburnum has proved of the greatest use in the writer's hands in cases in which women have contracted the habit of aborting. In these cases the fluid extract in dram doses, or preferably a decoction prepared from the fresh bark of the root, in half-ounce doses, should be administered three or four times daily from the time pregnancy is suspected till several weeks have elapsed after the usual period of aborting. One word of caution is necessary as to the use of haw in threatened abortion. In cases characterized by much hemorrhage, the vitality of the embryo is probably lost, and it is hardly worth one's while to try to save it, and in these cases haw may prove a dangerous remedy. The bleeding is caused by a detachment of the placenta; the only means of checking the hemorrhage is the closing of the torn uterine sinuses by the contraction of the uterus, and haw by its paralyzant action may effectually prevent this contraction, and thus add greatly to the danger of death from hemorrhage. Or again, haw, by controlling the expulsive efforts of the womb, may cause the retention of a decomposing mass, and thus favor the production of septicemia. A large number of pregnant women suffer with what the writer is in the habit of styling irritable uterus. At any time during pregnancy, but especially during the later months, the womb may become fretful under its burden, and then occur frequent slight contractions, which annoy the woman and keep up tenderness and a sore feeling in the lower part of the abdomen. These cases are speedily relieved by moderate doses of viburnum. In the false pains that often harass a woman for days before the onset of labor, and in the after-pains of confinement, haw will often relieve.

The preparations of haw that I have used are the solid extract, in doses of from five to ten grains; the fluid extract, in doses varying from a dram to half an ounce, or, what is far preferable, a decoction prepared as follows, viz.: Four ounces of the bark of the fresh root are added to three pints of cold water in a porcelain vessel, and the whole boiled gently till only a quart of fluid remains. The fluid portion is now strained away, and the juices remaining in the bark are extracted under pressure and added to the decoction. Of this the dose is from one-half to one ounce, repeated in accordance with the demands of the case and the resulting effect.

A PRACTICAL TEST FOR AIR-IMPURITY.[1]

By HARRY H. BOOM, M.D.,
LECTURER ON HYGIENE, MEDICO-CHIRURGICAL COLLEGE, PHILADELPHIA.

Hygienists and chemists tell us that pure atmospheric air contains about four parts or volumes of carbonic oxide (CO_2) in every ten thousand parts of air. When symptoms of discomfort or disease result from breathing the air of inhabited, poorly ventilated rooms, such symptoms are due principally to the presence of impurities given off in respiration. It has been authoritatively stated, that, as such respiratory impurities are given off to the air they are mixed with a fixed quantity of carbonic oxide; in other words, with each expiration of the individual there is exhaled carbonic oxide, respiratory impurities, mostly organic in character, vapor of water, and other materials.

Although doubted by some observers, the view is still held by most sanitarians, that by estimating the amount of carbonic oxide in habitable rooms we may obtain an approximate measure of respiratory impurities present. Dr. de Chaumont tells us that when the air has added to it respiratory impurities in amount represented by two parts of carbonic oxide in the ten thousand, in addition to the four parts of carbonic oxide existing naturally in air, such air does not differ materially from pure outside air in its effect upon health. When, however, the proportion of carbonic oxide, and its accompanying impurities, exceed six parts or volumes in ten thousand parts of air in the room, the health of the individual suffers. This, then, is the permissible limit of respiratory impurities.

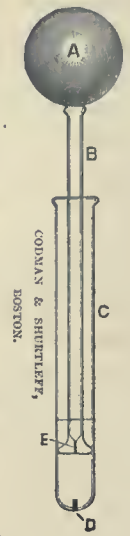
If we pass a stream of carbonic oxide gas through lime-water, a precipitation of carbonate of lime takes place, causing the lime-water to become turbid. This fact is applied by Dr. Angus Smith in the "household" and the "minimetric" methods of air-testing described by him. Recently, Professor Wolpert, a noted German meteorologist, has devised an instrument that he calls an "air-tester."

Dr. S. W. Abbott describes this instrument in the *Boston Medical and Surgical Journal*.[2] It consists of a simple rubber bulb (A) of a capacity of twenty-eight cubic centimeters, a glass outlet-tube (B) with a constriction near its extremity (E). A glass test-tube twelve centimeters in length (C) and two millimeters in diameter, has a horizontal mark near the bottom, indicating the point to which it must be

[1] Read before the Philadelphia Medico-Legal Society, January 26, 1892.

[2] See Rohé. Text-book of Hygiene. Second Edition.

filled with perfectly clear saturated lime-water to contain three cubic centimeters. The bottom of the test-tube is whitened and has a black mark stamped upon it (D).



In order to use Wolpert's "air-tester," pour clear saturated lime-water into the test-tube until it reaches the horizontal mark. The glass outlet-tube attached to the rubber bulb is inserted nearly to the bottom of the test-tube and below the surface of the lime-water. The rubber bulb is compressed firmly and twenty-eight cubic centimeters of air are forced through the lime-water. Without relaxing the compression of the rubber bulb, withdraw the outlet-tube from the lime-water and then allow the bulb to refill with the air of the room. Again insert the outlet-tube in the lime-water and compress the bulb, as before. Continue forcing air through the lime-water in this manner until the carbonic oxide present in the air has rendered the lime-water so turbid that when we look downward through the lime-water, we can no longer distinguish the black mark (D) on the bottom of the test-tube. If this obscuration is effected by one bulbful of air (twenty-eight cubic centimeters) carbonic oxide is present in the proportion of 200 parts to 10,000 parts of air. If it requires two bulbfuls of air, carbonic oxide is present in the proportion of 100 parts. If thirty-three or thirty-four bulbfuls of air are required to render the lime-water turbid, obscuring the black mark, carbonic oxide is present only to the permissible limit of six parts in ten thousand.

As this method of air examination appeared so practical and required so few appliances, it seemed worthy of attention. On application at the stores of our city, however, the instrument could not be obtained. It was found impossible, without considerable cost, to obtain a rubber bulb of exactly twenty-eight cubic centimeters capacity. Furthermore, after such a bulb was made, even though the utmost care was used in compressing it, all the air which it contained was not expelled, so that a compression of the bulb did not cause quite twenty-eight cubic centimeters of air to pass through the lime-water. Another objection was that as the bulb had but one opening for the admission of air, that through the outlet-tube, lime-water would be sucked up into the outlet-tube and bulb if the compression of the bulb was relaxed in the slightest degree before the outlet-tube was withdrawn from the lime-water. When lime-water gained entrance to the rubber bulb in this manner, part of it remained in the bulb, thus lessening the quantity of lime-water operated upon, and part of the lime-water sucked up returned to the test-tube, carrying with it powdered rubber, which caused a turbidity in excess of that produced by the carbonic oxide. The required diameter of the test-tube, two millimeters, was so small as to constitute a decided objection.

For all these reasons I have been led to propose a modification of the "air-tester" of Professor Wolpert, and of the manner of using the "air-tester." It is as follows:

1. Select a test-tube of *any* size and make a horizontal mark upon its side at *any* point.

2. Take a rubber bulb having one valve and to the *unvalved* extremity bind a glass tube, long enough to reach to the bottom of the test-tube selected, and our apparatus is complete. For the rubber bulb we may use the hand bulb of a spray-producing apparatus.

We must now "standardize" our apparatus. To do this we carry the apparatus to a place the air of which we know to be pure, or the air of which contains four parts of carbonic oxide in ten thousand parts of air. Fill the test-tube with clear, saturated lime-water, up to the horizontal mark made upon the side of the tube. Insert the outlet-tube, attached to the rubber bulb, below the surface of the lime-water in the test-tube, and compress the bulb; without withdrawing the outlet-tube from the lime-water, allow the bulb to refill slowly, through the valved opening, with the air of the room. Continue compressing the bulb and thus forcing air through the lime-water, until an ink line, or mark, made upon a white card can no longer be distinguished when the card is held against the bottom of the test-tube and we look downward through the turbid lime-water. Multiply, now, the number of times we have compressed the rubber bulb by four and write the product plainly upon the apparatus. Our instrument is now "standardized" and is ready for use. To make use of it, we put it in the hands of the nurse or attendant, telling her to test the air of the sick-room at stated intervals. She is to divide

the number of bulbfuls of air of the room necessary to render the lime-water turbid (obscure an ink line on a white surface) into the number written upon the apparatus, and when the quotient exceeds six the quantity of respiratory impurities, as measured by carbonic oxide in the air of the room, has passed the permissible limit, and the air in the room must be changed more rapidly.

When we standardize our instrument we write the product of the number of bulbfuls of air multiplied by four upon our apparatus to avoid giving the nurse the necessity for the following calculation:

The quantity of air of the sick-room required to produce turbidity in lime-water is to the quantity (or number of bulbfuls) of pure air required to produce turbidity in lime-water, as the quantity of carbonic oxide present in pure air (four parts) is to x, or the quantity of carbonic oxide in the air of the sick-room. Now, if on standardizing our apparatus it required twenty bulbfuls of pure air to cause turbidity of the lime-water, and in the sick-room ten bulbfuls of air caused the same amount of turbidity in lime-water, then—

Air of room.		Pure air.		Parts CO_2.	
10	:	20	::	4	: $x = 8$ parts CO_2 in 10,000.

Then, if the product of the number of bulbfuls of pure air multiplied by four, be written upon the apparatus, the only calculation the nurse will be called upon to perform is that of dividing the number of times she compresses the bulb into the number written upon the apparatus.

The instrument may be standardized in other than pure air, provided that by some reliable test, as Pettenkofer's, we determine exactly how many parts of carbonic oxide are present. If our apparatus be standardized with air at a temperature of 68° to 70° F., it will render unnecessary any correction for differences in temperature, as air in rooms usually has this temperature.

As an example of the usefulness of this little instrument the following is cited:

An instrument marked 80 was given to a nurse attending a case of typhoid fever, and upon the clinical chart she notes:

2 P.M. Ten compressions, or 8 parts CO_2 [$80 \div 10 = 8$ CO_2]. More fresh air admitted.

4 P.M. Fifteen compressions, or 5+ parts CO_2.

6 P.M. Twelve compressions, or 6.7 parts CO_2. More fresh air admitted to the room.

The time required for each examination was but from three to five minutes. After each examination the test-tube should be washed with vinegar to remove any carbonate of lime remaining upon the bottom or sides of the tube, and then well rinsed with water.

In closing this subject, I would give warning not to trust to the sense of smell for judging the state of purity of air in a room. Many poisonous exhalations have no smell, and, also, as the sense of smell is soon blunted, nurses are often unaware of the extremely unhealthy condition of the air of a room in which they remain for many hours. On first entering a room we may find the air quite offensive, yet before we leave the room, after a short call, our sense of smell is so blunted that we no longer perceive any difference between the air of the room and the pure external air. For this reason I would urge the necessity of frequently repeated examinations of the air of rooms, especially of rooms occupied by the sick.

ASCOCOCCUS GANGRENOSUS: REPORT OF A CASE OF GANGRENE, WITH BACTERIOLOGIC INVESTIGATION.[1]

By D. BEVAN, M.D.,
ASSISTANT, DEPARTMENT OF HYGIENE, JEFFERSON MEDICAL COLLEGE, PHILADELPHIA.

Case I.—Mr. B., a colored man, seventy-two years of age, whose general health had always been good, and whose habits had been unexceptional, had never suffered from any prolonged illness and there was no history of inebriety or venereal disease. On November 27th, 1890, the patient complained of intense pain in the great toe of his right foot, associated with a feeling of coldness and slight discoloration, the skin having a pinkish hue. In the course of a few days the discoloration became more intense, and on the outer side near the extremity of the nail, intensely black, shading from black to purple, from purple to reddish pink, the latter color extending up some distance on the foot. About the middle of December, Dr. Hearn saw the case and pronounced it one of senile gangrene; it had then developed an intensely penetrating and horrible odor, that could not be suppressed by the most active deodorants. The line of gangrene progressed slowly until December 23d, when it reached a line extending around the foot, just posteriorly to the tarso-metatarsal articulation on the upper surface, and involving the entire plantar surface of the foot, extending barely as far back as the heel. The line of demarcation developed and all further progress for the time seemed arrested. The pain was still excruciating and the disagreeable odor had not diminished. No constant record of temperature was kept, but there did not seem to be any very marked elevation; upon several occasions it ran as high as 101⅘°; there were no rigors and no evidence of septic absorption. The patient's general condition was very good; intense pain had kept him awake and annoyed him a great deal, but he did not seem to have lost strength. On December 27th, it was decided to amputate the limb. On account

[1] This report represents a part of the Thesis that secured THE MEDICAL NEWS Prize, and is one of a series of observations and experiments carried on in the Laboratory of Pathology under the supervision of Dr. Coplin, Demonstrator of Pathology and Lecturer on Hygiene.

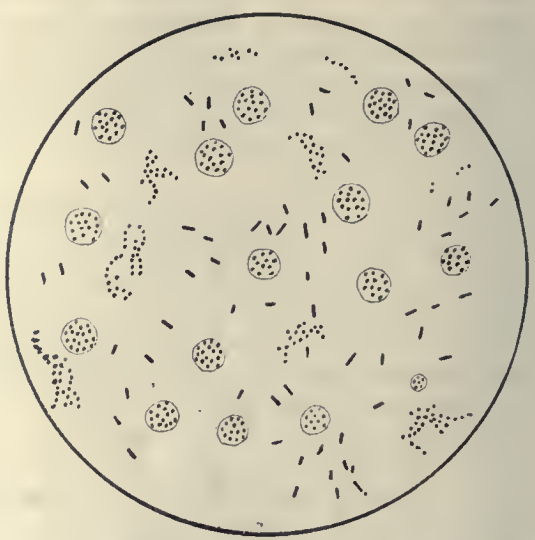
of his age, it was thought that the shock would be less if the operation could be rendered bloodless by the use of Esmarch's bandage. The operation was done under the strictest antiseptic precautions. The line of amputation was such as to divide the tibia just below the tubercle. The larger bloodvessels were remarkably calcareous, and held the ligatures very poorly. The patient bore the anesthetic (ether) very well indeed; his pulse seemed stronger and his color better after the operation than it had been before. The flaps did not retract as far as they should have done, and did not seem to regain their color, looked white, and the elasticity of the skin seemed diminished. The limb was enveloped in cotton and surrounded by hot-water bags, these being renewed from time to time in order to insure the application of abundant warmth. The pain almost entirely disappeared; prior to the operation, he had been taking from a grain and a half to three grains of morphine per diem; he now passed a quiet night and enjoyed some sleep, although there had been administered but a quarter of a grain of morphine immediately after the operation, which was at 3 P.M. On the following day the dressings were removed and found but slightly blood-stained; the flaps did not seem to have regained their color, and there was no evidence of any inflammation along or near the point of suturing. The wound was washed with a one to one thousand bichloride of mercury solution and again dressed in the bichloride gauze; hot water was reapplied as had been done in the first dressing. The patient's general condition seemed very good indeed; he had no pain and felt no particular discomfort in the limb; he was taking nine grains of quinine each day, supplemented by the very best food that could be obtained, and the administration of three whiskey punches in the twenty-four hours. He passed a very quiet night, and on the following day—the third day after the operation—seemed to be feeling very well; there was no perceptible weakness, and the wound was again dressed as before. On the following day the pain had returned with renewed intensity, and the wound again gave off the penetrating, peculiar odor so characteristic of senile gangrene. At this dressing the entire flaps were gangrenous, the intense black fading off through several successive changes in hue, and again extending in irregular lines over the external and upper surface of the knee-joint. The gangrenous wound was thoroughly washed out with peroxide of hydrogen in the hope of neutralizing the odor, followed by washing with bichloride of mercury solution and the reapplication of antiseptic gauze. On the fifth, sixth, seventh, and eighth days his condition remained about the same and the gangrene did not seem to extend. On the ninth day after the operation a bedsore had developed on one hip; this emitted the same fetid odor and was the seat of the same intense pain that had been present in the limb.

The patient was perceptibly weaker and sinking fast; although taking from three to five grains of morphine a day, his suffering was terrible; he no longer took nourishment, could not sleep; chills, at first slight, afterward more severe, were associated with and followed by intense pain and fever. The gangrenous process in the leg stopped at the knee-joint and did not seem to have any tendency to progress further. The bedsore increased in size until, on the twelfth day after the operation, it was as large as a dinner-plate, its surface covered by a black sloughing mass. On the thirteenth day his consciousness for the first time gave way, and on the morning of the fourteenth day he died.

It was impossible to obtain the amputated limb, as he had expressed a desire that it be buried; permission, however, was obtained to remove several small pieces of the sloughing tissue, as well as some of the bloodvessels, nerves, and pieces of muscle. The bloodvessels were intensely calcareous, the anterior and posterior tibials being the seat of the most marked atheroma and their lumen so diminished as to barely permit of the introduction of the smallest surgical needle.

The specimens of gangrenous tissue referred to were brought to the laboratory and the following experiments were made:

Tubes A, B, C, D, and E were inoculated on December 27th, and in twenty-four hours, at the temperature of the room, which averaged 70° F.,



Dry gangrene. Ascococci, micrococci, and bacilli—from agar-agar culture. Beck's $\frac{1}{12}$ homogeneous immersion, Oc. 2. (Camera lucida drawing.)

developed a considerable growth, which was of ashen-gray color, opaque, and glistening. It penetrated the surface deeply and rapidly in dense clouds. It did not liquefy the agar. A horrible odor emanated from the tubes, closely resembling that which is so characteristic of senile gangrene.

Slides from these cultures showed cocci that somewhat resembled streptococci, but were considerably smaller than streptococci pyogenes. There were also present some few small bacilli. The cocci

stained but poorly with Ziehl-Neelsen's carbol-fuchsin solution, but evinced intense affinity for Weigert-Ehrlich's methyl-violet aniline stain. These spreads were all treated by Gram's method and mounted in Canada balsam.

The cultures were carried on through several generations and cover-glass impressions made, to determine the class to which they belonged. They were stained with methyl-violet aniline and mounted as previously stated. A microscopic examination revealed what was apparently a hyaline circular capsule containing many cocci, a number of which were stained of an intense blue color. No bacilli were perceived. There were other cocci present, arranged as monococci and diplococci.

On February 16th, at 4 P.M., a culture of these microbes was injected into the subcutaneous tissue of the thigh of a guinea-pig. On the following morning a small and intensely black spot, about the size of a split-pea, had formed, with a line of demarcation sharply defined. The gangrenous area was somewhat depressed, dry, and very hard. The animal was not active as usual, did not use the leg in locomotion, but held it close to the side of the body. It still continued to take food, although the amount, as compared with the quantity it usually devoured, was extremely small. The gangrenous area increased gradually day by day, and the animal absolutely lost the use of the limb. Attempts to move it caused great suffering, crying, and struggling. On the 20th a small circumscribed gangrenous area upon the abdomen, midway between the xiphoid appendix and pubes, was observed, and connecting it with the gangrenous process in the thigh, a round indurated band of tissue, apparently about one-fourth of an inch in diameter. After the 23d the pig rapidly declined, the prostration became extreme, and it did not appear to notice food placed in its cage, nor did it drink water. From this time it passed into a comatose condition. At intervals of about half an hour it would for a minute or two rouse itself and endeavor to stand, only to fall over on its side, all the while uttering the most plaintive cries. This condition continued, the stupor becoming more profound, and the intervals between its attempts to stand and the paroxysms of crying more prolonged. Its head sank and rested upon the bottom of the cage and its hair appeared to stand on end. While observing it on the evening of the 24th, at about 4.30 o'clock, it suddenly raised itself upon its forelegs, swayed from side to side several times, fell over, and expired.

After a careful dissection, the necropsy showed that the muscles of the abdomen, immediately subjacent to the gangrenous tissues alluded to, were becoming involved, being of a dull slate-color, and more easily broken down than healthy muscles. The same odor that was noticed in detailing the history of the case was present, although not so marked.

Cover-glass impressions of the blood contained in the heart, show by the staining of aniline methyl-violet, by Gram's method, first treating with acetic acid, numerous cocci that arrange themselves as monococci, diplococci, and tetracocci. Tubes were also inoculated from this blood, from which developed a mixed growth of bacilli and cocci, the former in by far the greater number. The macroscopic appearance of the liver seemed to indicate the existence of metastatic abscess, and as soon as the liver attains the required consistency, it will be cut and microscopic examination made.

One of the peculiar features of the case of the old man with senile gangrene was the apparent limitation of the gangrenous process, which extended so far, and then the line of demarcation formed after the amputation and reëstablishment of the gangrene in the stump; it will be remembered that a second necrotic area formed upon the buttocks, which also became circumscribed. Now comparing the symptoms, etc., of this case with that of the guinea-pig, in which gangrene was produced by the subcutaneous injection of microörganisms cultivated from pieces of tissue taken from the amputated limb, one cannot fail to recognize the similarity or identity of the two conditions.

In considering this case, and bearing in mind the guinea-pig experiment, the writer concludes that the immediate cause of death in such cases is the entrance into the circulation of these microbes, their proliferation and the production of ptomaïnes, and septicemia. That the flaps after amputation should have become gangrenous is not surprising, and, in my opinion, cannot be attributed wholly or directly to the diseased condition of the arteries. I believe that the physiologic resistance of the cells, supplied with but a small quantity of blood, was considerably diminished, and that the roughened intima of the bloodvessels furnished a condition preëminently suited for the mural implantation of the microbes contained in the circulating blood; that the microbes were either present or effected an entrance into the blood at the time of the operation, and that they subsequently lodged in the flaps and proceeded to exert upon the tissues their specific pathogenic action.

The only explanation that I can offer as to why the gangrene did not manifest itself earlier after the amputation, is that through the agency of the bichloride, the organisms were prevented from localizing themselves, but that so soon as union had commenced, and the inhibiting and destroying influence of the antiseptic was removed, they established themselves in this *locus minoris resistentia*, and from

this point of vantage so thoroughly and rapidly invaded the tissues, that nothing could stay their progress.

The application of Esmarch's bandage may have also had an important rôle in the production of gangrene in the stump. The diseased condition of the arteries rendering them exceedingly brittle, portions may have broken down and the calcareous particles have been washed into the general circulation.

CLINICAL MEMORANDA.

A NOTE ON ASTHENOPIA AND INTRA-NASAL DISEASE.

BY G. E. DE SCHWEINITZ, M.D.,
PROFESSOR OF DISEASES OF THE EYE IN THE PHILADELPHIA POLYCLINIC; OPHTHALMIC SURGEON TO THE PHILADELPHIA AND CHILDREN'S HOSPITALS.

IT is well established that a large number of ocular disorders (blepharitis, chronic hyperemia of the conjunctiva, phlyctenular kerato-conjunctivitis, and dacryocystitis) may have their origin in intra-nasal disease. Less frequently there is an association between atrophic conditions of the nasal mucous membrane and degenerative changes in the optic nerve, and quite a number of observations have been recorded in which a series of symptoms referred to the eyes, and in which the eyes themselves, in so far as the balance of the external ocular muscles and the refractive condition are concerned, were abnormal, nevertheless depended upon naso-pharyngeal disease. The cases which follow belong to the last class, and illustrate one or two instructive points:

CASE I.—Miss M., aged nineteen, unmarried, reported for treatment October 23, 1890, with the following statement: She had worn glasses since she was eight years of age, in the hope of obtaining relief for almost constant headache. Frequent changes in the correction had been made, but no glass had ever been prescribed that gave her much relief. There were stubborn asthenopia and post-ocular and supra-orbital pain, aggravated by exposure to sunlight, and changed into an explosion of violent general head-pain on the slightest use of her eyes. Headache on rising was usually present. The family history was good, and her general health was perfect. The ophthalmoscope revealed on each side an oval, over-capillary optic disc. There was slight absorption of the retinal pigmented epithelium and some exposure of the larger vessels of the choroid. Glistening reflexes played through each macular region. After the use of atropine, the refractive error was found to be the following:

O. D. + sph. 1.50 D. ⌒ + cyl. 0.62 D. axis V = $\frac{6}{6}$.
O. S. + sph. 2.25 D. ⌒ + cyl. 0.62 D. axis 75 = $\frac{6}{6}$.

The muscular balance was as follows: Esophoria, 3°; exophoria in accommodation, 3°; no manifest hyperphoria. Practically no improvement took place, in spite of all reasonable treatment.

Attracted by the persistent morning headache and a slightly nasal voice, an examination of the posterior pharynx was made, revealing the evidences of some post-nasal catarrh. The patient was then referred to Dr. J. Solis-Cohen, who reported as follows: "There is chronic suppurative disease of the frontal sinus and ethmoidal cells, with consequent chronic inflammation of the mucous surfaces over which the discharges trickle and become adherent. The treatment will require several months, but will be very satisfactory in its results."

Dr. Cohen's prophecy was thoroughly fulfilled. At the end of a month she reported herself much better. At her last visit, December 10, 1891, or more than a year after her original application for treatment, her vision had risen to $\frac{6}{5}$, the over-capillarity of the optic disc had subsided, and to use her own words, "I am practically without headache and have never known so happy a year."

CASE II.—Miss B., aged thirty, unmarried, reported for treatment May 20, 1891, and gave the following history: As a school-girl she suffered much with her eyes and with headache, and she was ordered glasses, but without much relief. She continued to receive ocular treatment for a number of years, consulting several surgeons, but experienced little relief and no lasting benefit. Her complaint was as follows: Much pain in the eyes, across the brows and directly in the nose; stubborn asthenopia, so that no work requiring the use of the eyes at close range could be performed for more than a few minutes at a time without bringing on violent pain, neuralgic in type. She was a slender woman of the neurasthenic type, but without disease to which a name could be given. Not exactly hysterical, she had become depressed by her long debarment from reasonable use of her eyes, and had undergone a somewhat prolonged "rest-cure." She was wearing the following combination:

O. D. + sph. 3.25 D. ⌒ + cyl. 0.62 D. axis V = $\frac{6}{6}$.
O. S. + sph. 2.75 D. ⌒ + cyl. 0.62 D. axis V = $\frac{6}{6}$.

Through these glasses there was esophoria of 4° for the distant point, and about the same amount in accommodation. At one time she had worn weak prisms for hyperphoria without benefit. At the time of the examination no hyperphoria could be demonstrated. There were no abnormalities in the eyeground other than those common to hypermetropic eyes.

Attracted by the situation of the pain, and by the fact, previously unmentioned, that the asthenopia and also the pain were liable to be present most severely in the early morning hours, or, at all events, after resting, an examination of the nasal regions was made, and sufficient abnormality to justify special treatment was evident. She was referred to Dr. Ralph W. Seiss, who reported as follows: "There is a distinct tender spot over the right antrum; the septum is much engorged, with a myxomatous and hypersensitive spot high up on the right side. The turbinals are somewhat vaso-paretic (causing occasional stenosis) and infiltrated. The pharynx and larynx show moderate secondary changes. I believe that a fine cautery point to the septum would give considerable relief, and free antral drainage (by removing stenosis about meatus) might give very decided results. The patient volunteered that my manipulations—pressure and cocaine—have lessened the pain temporarily."

After a week's nasal treatment the patient acknowledged distinct improvement. From time to time reports came from this patient, always of a favorable character, and at her last visit, December 26, 1891, she was improved in every way. The neuralgia was practically gone, or, to use her own expression, "was an unusual occurrence." The eye-endurance was still limited, but reading or similar occupation could be maintained for a couple of hours without inconvenience.

Case III.—Mr. E. W., aged thirty-seven, married, reported for treatment December 20, 1890, and gave the following history: For some years he has experienced pain above the eyes and in the occiput, aggravated by reading or similar use of the eyes. The ocular pain is apt to be worse in the morning, and the use of his eyes has been greatly abridged, owing to the symptoms that have just been described, and in spite of the use of glasses. The patient was in good general health, and with the exception of the use of tobacco, had no bad habits. In each eye there was an oval, rather pallid optic disc, unduly full retinal veins, and general woolliness of the choroid. After cumulative instillations of homatropine the refractive error was found to be

O. D. + sph. 0.50 D. ⌒ + cyl. 0.75 D. axis V = $\frac{6}{6}$.
O. S. + sph. 0.50 D. ⌒ + cyl. 0.62 D. axis V = $\frac{6}{6}$.

There was exophoria of 5° degrees in accommodation; no other disturbance of the muscular balance.

At first the use of these glasses afforded some relief, chiefly in the amelioration of the occipital pain; later, this, as well as the ocular pain and asthenopia, returned. After an examination of the naso-pharyngeal region, the patient was referred to Dr. Ralph W. Seiss for special treatment. The following is his report: "There is rhino-tracheitis of average type, with the following peculiar features: The capillary circulation is markedly engorged (deep-red mottling without swelling); the turbinals are purple; the lateral areas of the pharynx are very much engorged, and the larynx so much so that the true and false cords are of about the same tint. There is probably congestion of the lining membrane of the sphenoid sinus."

Unfortunately the patient did not attend with great regularity, but after having paid Dr. Seiss three visits, and having received appropriate treatment, he was so much improved that he doubted the necessity of further attendance. The fact that he has not reported makes it seem likely that his relief has been permanent.

It is evident that these cases do not belong to the class of the ordinary nasal headaches which are so common in catarrhal patients. They are further interesting because in each instance the refractive error and the faulty muscular balance were of such a character that the symptoms of which the patients complained would naturally be ascribed to these anomalies; and they are finally worthy of note because the patients were, to a great extent, unconscious of, or at least indifferent to, very serious and decided lesions in the naso-pharyngeal region. The definite relationship of the nasal and ocular difficulties in these cases seems well established, and it is evident that the treatment of each region had its special value in bringing about the cure. It is also plain that the careful examination and treatment of the eyes were not alone sufficient to alleviate the asthenopia, headache, and ocular pain which, although they seem in a large measure to have been dependent upon intranasal disease, were none the less provoked by the use of the eyes, and on this account the real cause of the difficulty might readily have escaped attention.

THE REMOVAL OF ADENOID GROWTHS FROM THE VAULT OF THE PHARYNX.[1]

By H. HOYLE BUTTS, M.D.,
INSTRUCTOR OF RHINOLOGY AND LARYNGOLOGY, NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL; ASSISTANT SURGEON TO THE MANHATTAN EYE AND EAR HOSPITAL, THROAT DEPARTMENT, NEW YORK.

There seems to be such diversity of opinion amongst rhinologists as to the best way of removing adenoid tissue from the vault of the pharynx, that I shall endeavor in this article to emphasize the advantages of one particular instrument as compared with others, and to attract the attention of such as are unfamiliar with its use by tracing the steps of the operation necessary for its successful completion.

The instrument is one that was devised by Dr. Gradle, of Chicago, and given to the profession some two years ago; it is known as the Gradle forceps. I will not enter into a minute description of the instrument, but think on inspection some of its claims for consideration will be apparent. I base my conclusions on one group of twenty-nine cases upon which I have operated during the past year, at the Manhattan Eye and Ear Hospital. As most of the subjects for operation are children under the age of twelve years, it seems to me absolutely necessary, for a complete removal of these growths at one time, that the patients should be etherized to the extent of abolishing the reflexes. It hardly seems requisite to enter a plea here for the use of general anesthesia, as who amongst us has not seen the terror depicted on the faces of our little patients when brought back for a second introduction of the forceps, when only cocaine had been previously employed. Certainly the time involved—from ten to twenty minutes—in administering ether and completing the operation is well spent, when one considers that henceforth, so far as that condition is concerned, one will not again have to operate on that child. The objection most frequently urged against general anesthesia in these cases, is the possibility of asphyxiation from blood or vomited matter finding its way into the larynx. This bugbear appears to have been given too great prominence, as in an experience of at least one hundred and fifty cases I have never seen the slightest inconvenience resulting. It should be remembered that by the time the mouth-gag has been adjusted and the usual digital examination made to locate the mass—meanwhile the patient inhaling pure air—we have only the primary stage of anesthesia to deal with. Such being the case, any substance is much more apt to find its way into the stomach than into the windpipe. In addition to this, the patient being in the dorsal position, with head extended and brought well over the end of the table, but little danger or difficulty will be encountered.

In reference to the location of adenoid growths occur-

[1] Read before the Section in Laryngology and Rhinology of the New York Academy of Medicine, January 27, 1892.

ring in the naso-pharynx of children, it appears to me that one is likely to get an erroneous impression from the text-books and special articles on that subject. Especially is this true when the symptom of mouth-breathing is not decidedly marked or exaggerated. On this account, having swept the choanæ with the forefinger and thus discovered their patency, one may be inclined to doubt the original diagnosis. Experience leads me to believe that more than 90 per cent. of the well-defined groups of adenoid tissue in children lie at a considerable distance behind the free margin of the vomer, and not in close proximity to it.

Criticism has frequently been made by the casual observer that the antero-posterior dimensions of the Gradle instrument seem too large for introduction into a small child, and that the blades are too short to reach the vault of an adult pharynx. In explanation of the first objection, it is only required to add that the instrument is introduced sideways, closed, and under the guidance of the forefinger of the left hand, at the same time drawing forward the relaxed velum. The feasibility of reaching the most distant part of the adult vault is easily demonstrated on a skull. The blades having passed behind the velum and being allowed to open, will be found perfectly free and movable. The growth having been included and firm upward pressure being exerted, it is removed *en masse* by a closing and twisting movement of the handles. As in tonsillotomy, the more force and power brought to bear, the more complete the result. There is absolutely no danger of wounding the surrounding parts, by an operator who is familiar with their anatomy. The hemorrhage is fairly free for a moment, but ceases spontaneously. It is seldom necessary to reintroduce the forceps, and any remaining roughness may be smoothed down with the finger-nail. The patient is then rolled over, face downward, and such blood as may have accumulated in the mouth and nasal chambers is allowed to escape. By this time consciousness usually returns, and the patient is able to proceed homeward in the course of half an hour, with instructions to keep perfectly quiet for twenty-four hours. After-treatment in the way of sprays, etc., has been abandoned, as the children seem to do as well without it.

The action of the forceps is a combination of both the cutting and torsion methods. The greater proportion of the growth is cut through, and the remaining slight attachment twisted off. It scarcely seems essential to contrast the Gradle forceps with the numerous other instruments at our command, when we consider its simplicity and perfect adaptability to the purpose. Other devices seem clumsy or futile in comparison, when the number of introductions and small amounts of tissue removed each time are remembered. In making so sweeping an assertion as this, I feel sure of arousing the objection of a number of gentlemen who have found the Gottstein curette sufficient to meet their wants. Unquestionably the Gottstein is a most valuable instrument, and approaches the Gradle instrument more nearly in usefulness than any of the others. The latter, however, possesses a few minor advantages in addition that would seem to make it preferable, namely, as introduced, closed, it occupies far less space and is more readily directed to any portion of the cavity, finds its way more deeply into the base of the growths, and, what to my mind is very satisfactory, retains the extirpated mass in the grasp of the blades until withdrawn. This is not true of the Gottstein, the severed tissue generally being lost and swallowed by the patient. Although hemorrhage is usually unimportant in these cases, unless we have to do with a "bleeder," yet I have observed that it is always more profuse after the use of the Gottstein curette. My query then is: What is left to be desired in an instrument that removes so large a mass at one effort, with safety and rapidity?

In this collection of cases the age ranged from two years to twenty-four years. The symptoms were those commonly observed in obstructive nasal respiration: vacuous expression, mouth-breathing, restless sleep with snoring, impaired hearing and quality of voice, more or less irritative cough, and a generally anemic appearance. Of these twenty-nine cases of adenoids of the vault, twelve, or nearly one-half, were accompanied by hypertrophied tonsils, which were removed at the same sitting but previous to the performance of the adenotomy. The patients have recently been examined, and, without exception, the results have been very gratifying. The amelioration of symptoms was apparent within the first few days. In fact, the usual report of the parent has been, that "the child slept better on the first night after operation than it had done since first troubled with catarrh." It occasionally happens, however, that a week or ten days' time will be required to demonstrate any marked improvement. This, I presume, may be accounted for by the fact that in such cases the hypertrophied glandular tissue is distributed over a larger area, and the increased mechanical interference necessary for its removal causes a more marked inflammatory reaction.

MEDICAL PROGRESS.

Lateral Anastomosis for Carcinoma of the Bowel.—At a recent meeting of the Philadelphia County Medical Society, ASHTON reported the case of a woman, twenty-eight years old, who for three months presented failure in health and loss of weight, with paroxysms of abdominal and pelvic pain, preceded by abdominal distention. There was obstinate constipation; and nausea and vomiting set in. Celiotomy was performed, and a large carcinomatous mass was found involving the ileum, with glandular metastasis. The extent of disease was so great that resection seemed dangerous, and a simple lateral anastomosis was established. Solid rubber oval rings were employed, together with the right-angle continuous suture. Irrigation was omitted, and no provision for drainage was deemed necessary. The entire operation occupied twenty-five minutes. The patient recovered without complication. Three months after the operation the patient had gained thirty-five pounds in weight, and was in general much improved. Stress is laid upon the following points:

The necessity of frequently douching the seat of operation with warm sterilized water, to prevent the dangers of infection and shock.

Rapidity in operating is of great importance to insure success.

Early feeding by the mouth should be employed in all cases, especially in those already weak and exhausted.

This does not add to the dangers of leaking, as the parts are perfectly secure if proper rings and additional sutures are employed.

An important factor in causing subsequent closure of the anastomotic opening is direct union between the edges of the incision. This danger may be materially lessened by using a steel punch in making the opening, by stitching together the edges of the serous and mucous coats of the bowel, by placing the lateral sutures of the ring as close as possible to the margins of the incision, and lastly by making the anastomotic opening sufficiently long and of an oval shape.

Obstruction of the Bowel by a Gall-stone.—Bircher (*Correspond.-bl. f. Schweizer Aerzte*, 1892, No. 5, p. 142) has reported the case of a woman, sixty-two years of age, who for two years had complained of anorexia, digestive derangement, and constipation. Three or four years and one year previously, there had been attacks of severe cardialgia, after which the urine was deeply colored, but no jaundice appeared. When the patient came under observation there had been severe abdominal pains, followed by vomiting that soon became fecal. The abdomen was soft and retracted, but on deep manipulation a sense of resistance was evident in the right hypogastric region. Tenderness and spontaneous pain developed a little below the ileo-cecal region. Upon opening the abdomen, the intestines were found free but reddened; there were no evidences of peritonitis. Further examination disclosed the presence of a hard body occluding the lumen of the small intestine. In this situation a fecal odor was perceptible and the bowel appeared to be ulcerated. On opening the bowel a stone was found and removed, and the bowel was resected for a distance of almost eight inches, and was closed by three rows of sutures. The woman died in collapse ten hours after the operation. An autopsy was not permitted. The stone was pear-shaped, more than two and a half inches in its longest diameter, one and a quarter in its greatest thickness, and weighed eight hundred grains. It consisted of a nucleus of cholesterin and a cortex of lime-salts of bilirubin.

Cholecystenterostomy for Gall-stones.—Helferich (*Deutsche med. Wochenschr.*, 1892, No. 8, p. 157) reports the case of a man, thirty-seven years old, who had had repeated attacks of hepatic colic, attended with jaundice, and clearly dependent upon the presence of biliary calculi. Surgical interference was decided upon. An incision was made midway between the costal margin and the border of the enlarged liver, and extended vertically in the linea alba to the ensiform cartilage. The liver was pressed upward and backward from above by an assistant, and the gall-bladder exposed. This viscus was pear-shaped and moderately tense, but contained no calculi; it was adherent to the inferior surface of the liver. Calculi were palpable in the ductus choledochus. The relations of the parts rendered incision of the duct, with removal of the stones and subsequent suture, inadvisable, if not impossible. With a view of affording at least palliative relief, openings were with considerable difficulty made in the gall-bladder and the first part of the jejunum, and the corresponding edges approximated, leaving an orifice of communication of the thickness of a lead-pencil. The patient made a satisfactory recovery.

The Etiology of Epidemic Dysentery.—In evidence of the view that dysentery is not etiologically dependent upon any single specific factor, Maggiora (*Centralbl. für Bakteriol. u. Parasitenk.*, Bd. xi, No. 6 u. 7, p. 173) has reported the results of microscopic examination of the feces in twenty cases of dysentery, with bacteriologic examination in eleven cases, during an epidemic involving more than two thousand persons. There were three deaths among the number. In addition to red and white blood-corpuseles, intestinal epithelium, mucus, oil-globules, and particles of food, large numbers of microörganisms were found in the stools. The bacterium coli commune was found in large numbers in all cases. Proteus vulgaris was found in almost all cases in moderate numbers. In six cases the liquefying fluorescence-bacillus was found. Of a large number of examinations the ameba coli was found in but one. In another case the paramecium coli was present. In some cases staphylococci and the bacillus pyocyaneus were found.

Pernicious Anemia, Atrophy of the Gastric Mucous Membrane, and Degeneration of the Spinal Cord.—At a meeting of the Medical Society of Hamburg, Eisenlohr (*Münchener medicin. Wochenschr.*, 1892, No. 5, p. 79) reported the case of a man, sixty years of age, who for three months had complained of general weakness. Digestion was not deranged, but there were motor weakness of the extremities, a spastic-paretic gait, and incontinence of urine and of feces. Paraplegia soon appeared. Sensibility was unimpaired, though the patellar reflexes were absent. There were, besides, marked anemia, heart-murmurs, and poikilocytosis, but no hemorrhage. Temporary diarrhea occurred, but presented nothing unusual. The patient died of exhaustion. At the autopsy a high degree of atrophy of the glandular structure of the stomach and intestines was found. There was parenchymatous cloudiness of the heart-muscle. The liver responded to tests for ammonium sulphide. The posterior columns of the spinal cord were degenerated.

The Relation of the Knee-jerks to Super-venosity.—In a preliminary communication, Hughlings Jackson (*Brit. Med. Journ.*, No. 1624, p. 326) records having found an absence of the knee-jerks in some cases of pulmonary emphysema in which the aëration of the blood was greatly interfered with. To confirm the accuracy of the observation he suggests that the knee-jerks be tested before and after the administration of oxygen to cyanotic patients. "If super-venosity is a cause of loss of the knee-jerks, the fact may be important with regard to the apoplectic state, and possibly somewhat with regard also to post-epileptic coma."

Hysteria in a Girl of Thirteen.—At a meeting of the New York Neurological Society, Leszynsky presented a girl, thirteen years old, in whom for two and a half years, following a frightful dream, paroxysms of causeless laughter and weeping had occurred. In the preceding year, menstruation set in and convulsive

seizures appeared, usually aggravated at the menstrual periods. The girl had had attacks of motor aphasia and others of mutism lasting for a week or more. The convulsions lasted at some times for many minutes, and at others for hours. Hysterogenic zones appeared at various parts of the body. There were visual hallucinations and occasionally maniacal attacks and movements of rotation and of combined rotation and retropulsion. The visual fields had been contracted. There had been transient hemiplegia. The knee-jerks were preserved, but feeble. There was no history of onanism or of ovarian disease. The general health appeared good.

The Influence of Light upon the Growth of Bacteria.—In comparative observations made upon the influence of sunlight and electric light upon the growth of cultures of bacilli of typhoid fever, GEISLER (*Centralbl. f. Bakteriol. u. Parasitenk.*, 1892, xi, 6 u. 7, p. 161) found that there was no qualitative difference between the two, only a quantitative difference—that is, both forms of light exerted an inhibitory influence upon the growth of the organisms on gelatin; sunlight, however, in greater degree than electric light. Not only the light-rays and the chemical rays, but also the heat-rays, participated in this influence. All the rays, except the red, exerted a retarding influence on the growth of the bacilli, greater in degree in proportion to the index of refraction and inversely to the wave-length. The influence exerted by both sunlight and electric light depended not only upon a direct action upon the bacilli, but also upon changes set up in the culture-medium.

Tetany of Gastric Origin.—BOUVERET and DEVIC (*Revue de Médecine*, 1892, Nos. 1 and 2), conclude a lengthy paper, detailing a large number of observations, by expressing the opinion that the tetany that sometimes appears in individuals with dilatation of the stomach is particularly associated with a condition of permanent hypersecretion, which results in the development of a toxic agent, which, injected into lower animals, gives rise to symptoms of spasm or of paralysis. The toxic agent is considered to be a modification of syntonin, which can be extracted from the peptones of normal digestion by alcohol in the presence of free hydrochloric acid. In cases of permanent hypersecretion, especially when associated with gastric retention, alcohol must thus be strictly interdicted. When tetany has appeared, the indication is to evacuate and wash out the stomach.

Aneurism of the Heart.—At a meeting of the Royal Society of Physicians of Vienna, KUNDRAT (*Internationale klin. Rundschau*, No. 8, 1892, p. 315) presented the heart of a patient that during life had presented symptoms of myocarditis. The organ was enormously enlarged. The right ventricle was as large as a fist; the left ventricle as large as two fists, and adherent to the thickened pericardium. The surface of the organ presented three prominences, one of which, half as large as an apple, presented an orifice communicating with the left ventricle; the second was as large as a hen's egg and separated from the adjacent third only by a cicatrix. The primary process had been a myocarditis, as indicated by the multiplicity and contiguity of the lesions.

THERAPEUTIC NOTES.

The Treatment of Hemorrhoids.—At a meeting of the Medical Society of London, LAUDER BRUNTON (*Lancet*, No. 3576, p. 583) dwelt upon the influence of cold and over-eating in the development of hemorrhoids. Mercurials, followed by mild salines, are useful in preventing hepatic congestion. Aloes, in large doses, may conduce to the development of hemorrhoids by overstimulation of the muscular coats of the rectum. Small doses, on the contrary, exert a beneficial influence. Hepatic congestion due to cold may be relieved by the application of hot-water bags to the nape of the neck and over the liver. Patients subject to hemorrhoids should become accustomed to emptying the bowels at night, so as to secure rest in the recumbent posture. When there is much irritability at the anus it is preferable to use a soft sponge and water instead of paper more or less harsh. A pledget of animal wool dipped in hamamelis and introduced into the rectum will act as a mechanical support and as an astringent. In obstinate cases an anal pad may afford great relief.

For Pediculi Pubis.—The following ointment may be applied topically for the removal of pediculi pubis, without danger of salivation:

℞.—Hydrarg. ammoniat. . . gr. xxxv.
Balsam. Peruvian. . . . ℥j.
Olei petrolei . . . . ℥ijss.
Lanolini . . . ad ℥viij.—M.

WHITLA.

For the Paroxysm of Asthma.—

℞.—Morphinæ sulphat. . . . gr. $\frac{1}{4}$.
Atropinæ sulphat. } . . āā gr. $\frac{1}{100}$.—M.
Nitro-glycerini }

S.—Add to sufficient sterile distilled water, and inject hypodermatically at the onset of the paroxysm.

FUSSELL.

For Otorrhea.—

℞.—Acid. boric. . . . . ℥ijss.
Glycerini } . . . . āā f℥j.—M.
Aquæ }

S.—Instil a quantity sufficient to fill the auditory canal three or four times daily. J. LEWIS SMITH.

Treatment of Diphtheria.—GAUCHER (*Gaz. des Hôpitaux*, 1891, No. 122) recommends the local application of the following formula in the treatment of diphtheria:

℞.—Acid. tartaric. . . . gr. xxiv.
Acid. carbolic. . . . ℥ij.
Spts. vini rect. . . . f℥iv.
Olei ricini . . . . f℥vj.
Camphoræ . . . . ℥j.—M.

The membrane upon the affected surfaces is first gently removed. The application is then carefully made. After an interval of ten minutes, the parts are generously irrigated with boiled water, or a 1 or 2 per cent. solution of carbolic acid. If symptoms of laryngeal obstruction arise, a 2 per cent. solution of carbolic acid is constantly vaporized in the sick-room.—*Centralbl. für die gesammte Therap.*, x, 3, p. 172.

The Medical News.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,
1004 WALNUT STREET,
PHILADELPHIA.

Subscription Price, Including Postage in North America.

PER ANNUM, IN ADVANCE . . . . . $4.00.
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,

SURGICAL INSTRUCTIONS FOR THE ENCOURAGEMENT OF VICE AND DEPRAVITY.

PERHAPS the physician is *not* "called upon to guard the morals of the community," though he that overlooks the intimate relation between immorality and unhealth can never be a sincere medical friend or a safe guide in the paths of hygiene.

If, however, we take but the narrow view of them that separate soul from body—or perhaps deny the reality of aught that is not carnal—even then it is hardly self-evident that the physician is called upon to aid in the debasement of public or private morals.

A recent number of one of our exchanges contains an article longer than seven columns, on "The Prophylaxis of Gonorrhea." All that the physician may legitimately teach on that subject needs but one word to be expressed completely and forcibly. That word, Chastity, is fittingly absent from among the thousands of words with which our cotemporary has not-graced its pages. The very types would have dropped from the forms had the attempt been made to introduce it into such companionship.

The article, it is true, does in a feeble way allude to the fact that one of the ways to "accomplish the exclusion of microörganisms" is "by avoiding exposure"—coupling it, however, with a shameless alternative, and intensifying the uncleanliness of the association by a mild deprecation of the alleged fact that "the majority of men greatly prefer the risk of infection to adopting *either* of these certain preventives."

In the low spirit of complaisant opportunism this "unfortunate" tendency is calmly accepted; and any possible fear that might deter the minority of men from emulating the majority, is sought to be dissipated by the assurance that if the voluptuary does but carefully follow certain directions elaborated in these seven columns of "libertinism made safe," the punishment provided for his vice may be surely avoided. Is the gonococcus, then, Nature's only avenging angel?

True, it is the duty of the physician to relieve suffering, to heal disease, no matter whether that suffering and disease be caused by unavoidable misfortune, by avoidable error, or by wilful vice. It is likewise his duty to point out how, by obeying natural laws, suffering and disease may be prevented. But this is a far different matter from pointing out how, notwithstanding deliberate infraction of natural laws, the suffering and disease that Nature has provided as penalties for such infraction may be avoided.

In the case under consideration, surgery is degraded from its high position as an alleviator of human misery to that of an abettor of vice; it is made, indeed, the servant of the bagnio. This involves a threefold prostitution: the unfortunate woman is made to prostitute her body; the man prostitutes not alone his body and soul, but what may be of more importance to mankind at large, his wealth,—for the greatest social misfortune is the abuse of wealth unto evil,—and, finally, the priest of HYGEIA prostitutes his altar to the "strange fires" of the Cyprian APHRODITE.

The medical profession should be heard with no uncertain voice on the great question here involved. Many a man has been sent to his ruin by the immoral, unhygienic, criminally sinful advice of miscalled physicians. We recall at this writing a brilliant youth who, at the critical period of his life, succumbed to the influence of a medical man—a college professor, now (shall we say happily?) deceased—as poor in moral principle as he was rich in all the intellectual force and social graces that attract the young and captivate the inex

perienced. Under this false physician's tutelage, the young man began a career of vice that directly led to forgery, flight, a father's "gray hairs brought in sorrow to the grave," the pecuniary ruin of a widowed and heart-broken mother. This is perhaps an extreme instance; yet it is but a single example out of many that we know, of the evil flowing from one singularly gifted man's malign advice.

It is not the religionist—the Puritan—only, who finds sexual immorality condemnable. Science abundantly confirms the message the Hebrews brought mankind from Sinai. The historian and the sociologist find in unchastity the prolific source of politic and economic woes. The evolutionist sees in promiscuity a survival of the instincts of the beast and of the practices of the savage. In the children of civilization it is a debasing atavism. Shall physicians endeavor to promote the progress of man from the bestial to the divine, or shall they facilitate his retrogression and degradation? What good purpose can be served by such an article as that published by our cotemporary? What base purposes can it not be made to further?

HIPPOCRATES was a heathen of the fifth century B. C. Contrast the oath that bears his name with this consummate product of the nineteenth century of Christianity.

THE SALTS OF STRONTIUM.

ATTENTION has recently been directed by various French observers, and especially LABORDE, GERMAIN SÉE, C. PAUL, and DUJARDIN-BEAUMETZ, to the therapeutic usefulness of the strontium salts. LABORDE[1] states that the toxicity originally attributed to strontium is due solely to the impurity of the commercial products formerly used, barium being the most common contamination.

SÉE credits VULPIAN, in 1885,[2] with the first attempt to make use of what he terms "the remarkable therapeutic properties of strontium salts."

The preparations employed in the experiments conducted at Paris were of absolute purity, and the results thus far reported seem to indicate that in strontium a valuable addition has been made to our resources. Whether or not the high laudations accorded to it will be found to be entirely deserved, must remain to be determined by future experience.

[1] Académie de Médecine de Paris, séances du 21 et 28 Juillet, 1891.

[2] Académie de Médecine, 28 Juillet, 1885.

The two salts of strontium thus far placed at the service of physicians, are the bromide and the lactate. The latter, according to SÉE, has a remarkable influence upon digestion and nutrition, probably due to a special action upon the stomach; whether local or general he does not state. The daily dose is from 8 to 12 grams (from 120 to 180 grains). It is employed in all conditions indicating the use of alkaline salts, in which it is said to be superior to the potassium, sodium, and lithium compounds, and in chronic nephritis, in which it is said to remarkably diminish the quantity of albumin excreted without increasing the flow of urinary water. In gouty nephritis, especially, it is said to be of great service. It likewise seems, from these observations, that a strontium salt—perhaps citrate or acetate, should the lactate be deemed inadvisable—might be advantageously employed in the treatment of acute as well as chronic rheumatism, and perhaps in the paroxysm of gout, as well as in the management of the gouty diathesis.

Strontium bromide will probably largely supersede potassium bromide in nearly all cases in which the latter has hitherto been administered for prolonged periods; and perhaps, when the price becomes more reasonable, strontium bromide will displace potassium bromide altogether. Not alone does it produce the sedative influence due to its halogen element, but on account of the superiority of its alkaline base, it avoids all the dangers to nutrition that have hitherto been so great a drawback to the use of the potassium and sodium compounds in the management of epilepsy and similar conditions. In fact, the French observers claim that strontium directly promotes nutrition, improving the action of the stomach and the urinary functions, when combined with bromine as well as in other forms. It is soluble in water in all proportions. It is said not to produce cutaneous eruptions, depression, anemia, or cerebral torpor. Even in large doses, it is said to be devoid of toxic power. It may be taken in doses of four grams (one dram) at each of the three daily meals.

Of thirty-two patients suffering from gastric dilatation, treated with strontium bromide and strontium lactate, SÉE[1] claims that the majority has been improved and some cured. In diabetes, likewise, it is claimed that strontium bromide reduces the quantity of sugar excreted; and that in the

[1] Académie de Médecine, October, 1891.

management of pulmonary tuberculosis it will find an important place in restraining cough and preventing the vomiting due to cough, at the same time producing its general tonic effect upon the stomach and digestive functions, and hence upon nutrition at large.

It would seem that other strontium salts, especially the iodide, chloride, fluoride, salicylate, and benzoate, ought to find many uses in therapeutics. It is to be observed that in the introduction of strontium into practical therapeutics and commercial pharmacy, manufacturers have supplied a demand originated by physicians; medical men have not been persuaded into creating a demand for the benefit of manufacturers.

THE PATHOLOGIST.

Do the readers of The News ever have special work for a pathologist? If so, do they ever think what the work of a pathologist is? Does it ever occur to them that he is a practising physician, in this respect occupying exactly the same position as they? That, at least in a majority of cases, he is also connected with some institution, and is much occupied in teaching? And, finally, for the foregoing reason, if for no other, that his time is valuable? In most cases the pathologist does his work at his leisure, if he has any. If a specimen is to be examined and reported upon, it may be not only inconvenient but often impossible for the pathologist to give an immediate report. Furthermore, it is to be remembered that, to be satisfactory, pathologic reports require tedious and prolonged researches, and much hard, earnest, and devoted labor. Aside from this, the pathologist not infrequently can make no report or examination until the tissue is sufficiently hardened for section-cutting. A physician has been known to call upon his pathologist with a tumor, and state that he would wait until the report could be given! Specimens of the nervous system require weeks, nay, in many cases months, before a scientific report can be made. Often, in so small a thing as the examination of urine, from twenty-four to forty-eight hours will, in many cases, be needed, especially when the sediment is deposited slowly, and the deposit of but small quantity. Sometimes the physician not infrequently asks for an immediate report, when this is not at all necessary. If the patient is dead, what is to be gained by rushing through the pathology of the case? Under such circumstances the sender must remember that his specimen will invariably be laid aside until those cases are examined upon which, for clinical purposes, an immediate diagnosis is needed. For example, if a liver is sent the pathologist, and on the same day he receives a small fragment of a tumor in which a diagnosis is wanted, the liver case must inevitably wait until the tumor-fragment has been examined. This is but just to the patient, and to the physician or surgeon who sends the specimen. In addition to the foregoing, the modern pathologist, if he has done any work at all, is not anxious to be rendering reports upon what many physicians state as merely an interesting case. He has, in all probability, examined many such interesting cases.

There is still another aspect of the case not usually taken into consideration: It may never have occurred to the physician that the pathologist is a consultant, and that in giving an expert opinion the pathologist shares responsibility in the case—that often an operation hangs upon his word. Under such circumstances should he not be paid for his work? Finally, if the case is incorrectly reported, he will certainly be blamed. Is there any serious objection, therefore, to giving him credit? As he occupies the position of a consultant, is he not worthy of the honor and the fee of a consultant? Not infrequently the proposition is made that the sender will pay expenses. If this means pay for the time consumed, then all is well—it should mean that. The next time that you have a specimen to send to the pathologist please remember that if you are to avail yourself of his knowledge he should be remunerated for his labor and his time, just as much as the oculist or the clinician, the work of these differing from that of the pathologist only in this, that the clinician considers the symptoms, and the pathologist the lesion.

DEATH FROM COCAINE.

"I have never seen it: *ergo*—"

No man's experience, however wide, can cover all the possibilities of disease and accident. It may be wise and well for one to say, "I have not seen it," when the possibility or likelihood of this or that pathologic or toxic accident is under discussion; but it is never wise and never well because of the perhaps happy limitation of one's own experience, to deny the reality of occurrences vouched

for by competent observers, and not in themselves incredible.

These remarks are prompted by the report in *L'Union Médicale* for December 22, 1891, of a death following the injection of half an ounce of a one and one-half per cent. solution of cocaine into the tunica vaginalis testis, preparatory to the injection of iodine for the cure of hydrocele.

The solution of cocaine was withdrawn after less than a minute and the iodine injected. In a little while the patient returned, complained of great weakness, had clonic and then tetanic convulsions, became comatose and died in cardiac syncope.

At the autopsy there was found general congestion of the meninges and lungs, mitral insufficency, and alcoholic lesions in the viscera. The tunica vaginalis did not communicate with the peritoneal cavity.

M. Richardiere, in whose service the accident occurred, stated that he had made autopsies in eleven cases in which death had resulted from the injection of cocaine.

In a recent discussion at one of our Philadelphia medical societies, several speakers were inclined to make light of the dangers attending the use of cocaine, on the ground that in their own practice no accident had happened. This was in the discussion, too, of a paper in which two cases of syncope and delirium were reported and several other cases—some of them fatal—were cited.

While far from wishing to restrict the legitimate use of cocaine, we do wish once more to emphasize the fact that the same caution should be observed in ascertaining individual susceptibility (idiosyncrasy) to this drug as in ascertaining the same fact with regard to opium, arsenic, and the like.

THE VALUE OF A TRADE-MARK.

Diuretin (Knoll) and theobromine sodio-salicylate are chemically the same. There is no patent, so far as we are aware, preventing the manufacture of the latter by any competent chemist. As a matter of fact, a pure preparation is upon the market from the laboratory of a most reliable chemist.

Diuretin is a copyrighted, or trade-marked, name. The preparation sold under that name costs $2.50 an ounce. A trustworthy preparation of the same thing, under its legitimate chemical name, costs fifty cents an ounce.

Would it be strange if, out of such profits, the proprietors of copyrighted, trade-marked, names of medicinal preparations could not afford to subsidize "medical" journals, special pleaders against the code, and writers of so-called "clinical reports"?

SELECTIONS.

THERAPEUTIC FRAUDS: HOW THE MEDICAL PROFESSION IS DECEIVED THEREBY.

As is evidenced by the tenor of the proceedings of the Minneapolis convention, the proprietary and patent medicine interests are prepared to go to any and all extremes to force their wares upon the medical profession. It, therefore, behooves every practitioner to scan carefully the character of the product brought to his notice and urged upon his acceptance. Especially dangerous is it to give a statement embodying advantages (real or supposed) attaching to any remedy of proprietary nature, since by erasures, emendations, etc., such, on appearing in print, are apt to present quite a different character from the original, and to embody considerably stronger and more definite commendation than was intended by the author.

Medical men should remember, proprietary interests are soulless, and influenced only by greed. The welfare of the ill and afflicted is the very last thing that enters into consideration, if, indeed, it ever cuts any figure at all. The aim is "the greatest profit with the least outlay."

That medicine is not an exact science is to be deplored, but, unfortunately, that which demands the utmost scientific care and acumen is the very factor that stands in the way of exactness. This also renders possible the success of the patent and proprietary medicine trades, and by means of the opprobrium that obtains in proportion to ignorance it is possible for these trades to obtain an influence that is exerted to the utmost to attain the desired ends.

For many years now proprietary interests have been steadily working to secure to their wares a semi-respectable and quasi-scientific standing. The tendency of the medical profession as a whole, and of their *clientèle*, to look to immediate and temporary, instead of future and actual, results has greatly aided the nostrum promoters in securing the aid, and on many occasions the confidence, of practitioners. Further, in many instances medical men who are careless of reputation, not animated by proper professional spirit, but seeing in their profession only means of money-getting, willingly act as "stool-pigeons," and prostitute themselves to these interests; they submit to be suborned and bribed to give utterance to laudations that have no tangible foundation, and it is a matter of regret that the number of this gentry is constantly increasing.

Again, therapeutics is burdened with an appalling list of proprietaries, and threatened with many more. Some are, perhaps, possessed of a measure of merit, but by far the greater number is undeserving of any confidence, while a large proportion masquerades under fancy, false, and misleading titles. Further, with a degree of power and insistence scarcely appreciable, an unusually large number is demanding (or preparing to

demand) recognition by the Pharmacopeia. Thus the attempt is slowly, insidiously, and none the less constantly being made to thrust these articles upon the medical and pharmaceutical profession by means of all the powerful machinery of political and individual interests, of monetary backing, etc., including bribery, false witness, and, in some instances, very close approaches to forgery.

The criminality of these procedures, which juggle with the lives and health of invalids and the sorrows of the afflicted, is a terrible comment upon our boasted nineteenth-century civilization.

We are led to the foregoing remarks, in part, by an exposure recently made in the columns of the *Bulletin of Pharmacy* for October and January last, regarding a trade-marked product termed "eucalyptol," put forth by an Australian firm; a product that, in spite of the claims of its proprietors (Sander & Sons) that they are the "only manufacturers of eucalyptol in the world," is as remote from being the article named as it is possible to be.

Some trite lessons as to the extent that fraud enters into marketing preparations of this class may be had by studying the moves of the proprietors of this fictitious eucalyptol.

They issued a circular, which has been distributed broadcast, purporting to be a translation of a paper on "Diphtheria," by Hugo Schulz, Professor at the University at Bonn, that is made to do duty as a direct laudation of their product, though Dr. Schulz, when communicated with, unreservedly repudiated the product, and denied all knowledge of the Sanders. His letter appears in the *Bulletin of Pharmacy;* further, in all his works Dr. Schulz speaks only relatively of oil of eucalyptus in diphtheria, declaring his preference, *first, last, and at all times*, for mercury.

A like trick is played with a paper of Prof. Mosler, of the University of Greifswald, published in No. 21 of the *Berlin. klin. Wochenschrift* for 1879. Widely separate paragraphs, having no relation to one another, are selected by the Sanders and deliberately garbled.

As further evidence of the character of the commendations published by the Sanders, the *Bulletin of Pharmacy* remarks as follows:

"In a circular sent out by 'Sander, M.D.,' of Dillon, Iowa, dated Sandhurst, Australia, July, 1891, appeared the names of eighty-five purported medical men, who are claimed as supporters of fictitious eucalyptol. One name is employed twice, which leaves properly but eighty-four. An analysis of this list shows the character of the evidence relied upon by the manufacturers to support their product. Four names after close investigation are demonstrated to have no tangible existence. Nineteen are arrant quacks, devoid of medical qualification. Thirty-three are doubtful; that is to say, cannot be found in Polk's register or in local directories, hence may be presumed to have no existence[1]—or perhaps are new graduates, consequently without experience and incompetent for evidence. In five instances there is no such name or post-office as that given.

"Of those having authority to practise medicine, eight wholly repudiate the Sanders and their product, twelve have their names and addresses distorted, and there remains a total of but three individuals of presumed reliability for evidence. From these three must be deducted the name of Dr. Bartholow, which is made to do duty as a quotation from the *Medical Brief*, but which, as it appeared in that journal, bears unmistakable evidence of being a paid advertisement. The standing of Dr. Bartholow is evidence sufficient he never gave countenance to such 'scheme of piratical procedure.'" —*Editorial in the American Lancet, March*, 1892.

[1] Several are already found to have no real existence, while others are from dentists, druggists, surgical instrument dealers, saloon-keepers, and others who are by the Sanders clothed with medical titles and authority. We have been shown a letter regarding one Osborne, quoted by Sander, resident of Cottageville, Ky., who is an itinerant peddler, has served several times in gaol for violation of the laws, has never studied medicine, and never pretended to practise.—Ed.

THE FUNCTION OF MYDRIATICS IN CORRECTING ERRORS OF REFRACTION.

"Nowadays the corneal astigmatism is measured with an ophthalmometer, and the rest of the work is easy with no mydriatic." This is the closing sentence in an editorial communication published in the *Post-Graduate* for February, 1892. With the main portion of this communication we are not at present concerned, but the sentence which has been quoted demands some consideration and a good deal of condemnation.

It is evident that refractive error may be corrected in one of three ways—first, by what the writer in the *Post-Graduate* is pleased to call "the ancient practice"—namely, paralyzing the function of the ciliary muscle with a mydriatic, and working out the refractive error with the trial lenses; second, with the shadow-test; and third, with an ophthalmometer.

It is fair to assume that a mydriatic exercises three functions—first, to paralyze the ciliary muscle; second, to dilate the pupil, and hence to facilitate a thorough examination of the refractive media and the periphery of the eye-ground; and third, to place the eye at complete physiological rest, so that the lesions so commonly present as the result of prolonged eye-strain may subside—not alone, we take it, merely because there is physiological rest, but because of a distinct sedative influence exercised by the drug.

We are very far from decrying either retinoscopy or the use of an ophthalmometer—both of them advances in practical ophthalmology of inestimable benefit; but we are also very far from believing that the high standard of refractive work which has been attained in this country, certainly in some portions of this country, will continue to maintain the position which it now holds, or will advance still further, if the doctrine is taught that the use of mydriatics is an "ancient practice," and that the measurement of corneal astigmatism with an ophthalmometer is always sufficient. A sentence in the last edition of Mr. Nettleship's excellent manual is *apropos:* "I think that there is reason to fear that the free use of retinoscopy by students, before they have mastered the more difficult 'direct method,' may tend to lower the present high quality of English ophthalmoscopic work." Equal dangers are the tendency to trust an

ophthalmometer too implicitly, to fail in the detection of low degrees of astigmatism, and, finally, to adjust glasses to eyes that are not fitted to wear them, because there has been an imperfect examination of the refractive media and periphery of the eye-ground, and because the results of eye-strain have not been eliminated by the sedative measures to which allusion has been made. An ophthalmometer should always be used, and in suitable cases a mydriatic may be excluded; indeed, it is readily granted that it is often unnecessary; but the doctrine that mydriatics should not be employed in the estimation of errors of refraction is unworthy of converts.—*Therapeutic Gazette, March* 15, 1892.

AN ASYLUM FOR SUPERANNUATED INSTRUMENTS.

ACCORDING to a London letter to the *American Practitioner and News* for January 16th, old and discarded surgical instruments can be put to a good purpose by being sent to missionaries in foreign lands. A benevolent member of the Royal College of Surgeons has made a suggestion that all old-fashioned and discarded surgical implements be brought out of their dark corners and placed in the hands of the secretaries of those societies which employ medical missionaries. The gentleman who makes this appeal states that he knows of an instance of a missionary who had no other instruments than an ordinary case-knife and a pair of scissors with which to remove the frozen foot of a North American Indian, in whose case an operation was so imperative that he proceeded to operate with these. Fortunately the patient survived. A beginning has already been made by forwarding certain superfluous instruments and appliances to the Missionary Training College in East London. Old operating-cases, dental instruments, tourniquets, trocars, sounds, catheters, etc., may all be welcome and find their best value in the hands of those lonely pioneers, many of whom are a hundred miles distant, perhaps more, from any possible assistance.

CORRESPONDENCE.

A PHYSICIAN'S OUTFIT.

To the Editor of THE MEDICAL NEWS,

SIR: In THE MEDICAL NEWS of November 28, 1891, there was an editorial on the subject of physicians dispensing their own medicines. I wish to give in brief my experience and my methods as regards this, for the information of some of the younger members of the profession who may have just begun or are about to begin practice. Some physicians dispense their own medicines from necessity, some from choice—the necessity or choice depending on how near they or their patients are to the nearest drug-store. I have done both prescribing and dispensing, and as a result of my experience would say, that with the exception of a few articles, I prefer to dispense my own medicines, even when a drug-store is only a few doors away. The reasons for doing this are well stated in the editorial referred to, and substantially agree with my experience. To my mind, these are the most important:

First. In the case of office-patients they are much more likely to pay cash at the time of the visit if they get the medicine then and there, than they are to pay for advice only and the prescription. I find no difficulty in charging an advance sufficient to pay the cost and a fair margin of profit on the medicine given. When the cost of the medicine is only trifling I charge no advance. In the case of patients with only a little money they will neglect to pay the doctor because they must save the money to pay for the medicine. When the doctor is his own druggist, he is more likely to get paid both for his advice and his medicine.

Second. When we dispense our own medicines a large share of the competition of homeopathy is removed. In fact, I have been not infrequently called a homeopath, because I mixed up medicine in a glass at the patient's house. The average layman's idea of a homeopathic physician is one who gives pleasant medicine and mixes it himself. I believe a large share of the popularity of homeopathy is due to this fact, rather than to any comprehension of or belief in the principles of Hahnemann.

Third. There is great saving in time, especially in acute cases. When the physician has the remedies with him, he can administer them at once, instead of being obliged to wait until the prescription can be filled at some drug-store.

Fourth. Safety. There is much less liability to errors of administration when the first dose is given by the physician himself (I refer now to house-visits).

The foregoing reasons all hold true when the physician has his druggist next door, as well as when, like myself, he has a country practice of from four to six miles' radius. In country towns a certain amount of personal dispensing is absolutely necessary, even if there be a drug-store in the town; because patients cannot be expected to send from three to six miles for the medicine after the doctor has made his visit. In my own field I carry the only drug-stock in town and hence do all my own dispensing for both office and house patients. I carry two satchels, one for buggy use, and a smaller one with fewer remedies for calls nearer home.

For the benefit of some of the younger men I will give the contents of my buggy-case, more as suggesting remedies than as laying down any rule as to what should be carried. In making the selection of remedies one's own preference and the season of the year are to be consulted, in summer the variety being a little different to that for winter. By having extra bottles of the various sizes fitting one's case, the variation in remedies is easily accomplished and without loss of time. Owing to the large number of excellent and reliable preparations of remedies now obtainable in the form of triturates and tablets, quite a variety can be carried in a small compass. These preparations are as palatable as the homeopathic remedies, while they have much greater therapeutic effect.

My buggy-case contains eighteen one-ounce vials, in which I carry: Potass. brom., in crystals; sodium salicylate, in powder; ammon. chloride, in crystals; pepsin saccharatum; potassium chlorate; sodium bicarb.; acetanilid; calomel $\frac{1}{8}$ gr., bismuth subnit. 2 gr., soda bicarb. 2 gr.—mixed in this proportion and labelled nausea powder (satisfactory in nine cases out of ten for

nausea); spts. æth. nit.; tr. digitalis; tr. opii deod.; ammon. carbonate, saturated solution, gr. xv to ʒj; alcohol; tr. cardamom co.; acid hydrochloric dil.; spts. ammon. aromatic; chloroform; and quin. sulph., in two-grain, sugar-coated compressed tablets (these, being flat, are readily swallowed, and have the additional advantage that very few people suspect them of containing quinine; if only one grain is wanted, they are readily cut in two).

There are eleven half-ounce bottles, containing: Tr. aconiti; tr. belladonnæ; lead acetate; chloral, in solution, gt. j to gr. j; tr. capsici; bismuth subnitrate; tr. nucis vomicæ; fl. ext. ergot; sugar of milk; pulv. ipecac. et opii; tablets—iron, arsenic, and strychnine.

There are twenty-four two-dram vials, containing: Caffeine citrate; tannin; calomel; Turpeth mineral; borax; persulph. iron; pulv. ipecac; fl. ext. ipecac; comp. tr. opium; and the following in tablets: "Hepatic" (containing euonymin $\frac{1}{8}$ gr., podophyllin $\frac{1}{20}$ gr., ipecac $\frac{1}{8}$ gr., calomel $\frac{1}{8}$ gr., aloin $\frac{1}{12}$ gr.); aloin $\frac{1}{5}$ gr.; strychnine $\frac{1}{80}$ gr.; ext. belladon. $\frac{1}{8}$ gr.; ext. cascaræ sag. $\frac{1}{8}$ gr.; calomel, $\frac{1}{10}$ gr.; soda, 1 gr.; "rhinitis" (containing quin. sulph. $\frac{1}{4}$ gr., ext. belladon. $\frac{1}{8}$ gr., camphor $\frac{1}{4}$ gr.); ammon. mur. comp. with codeia (containing ammon. mur. $\frac{1}{4}$ gr., licorice $\frac{1}{10}$ gr., cubebs $\frac{1}{8}$ gr., codeia $\frac{1}{25}$ gr.); "sciatica" (containing tr. aconite $\frac{3}{4}$ ♏, tr. bellad, $\frac{3}{4}$ ♏, cimicifuga, $\frac{3}{4}$ ♏, tr. colchicum $\frac{3}{4}$ ♏—a very satisfactory combination); calomel, $\frac{1}{4}$ gr.; Dover's powder, gr. j; rhubarb and soda; morphine sulph., $\frac{1}{4}$ gr.; nitro-glycerin, $\frac{1}{100}$ gr.; calcium sulph., $\frac{1}{10}$ gr.; "fever" (containing tr. acon. 1 ♏, morph. sulph. $\frac{1}{20}$ gr., tartar emetic $\frac{1}{50}$ gr., ipecac $\frac{1}{8}$ gr.); nitro-glycerin comp. (containing nitro-glycerin $\frac{1}{100}$ gr., tr. digitalis ♏ij, tr. strophanth. ♏ij, tr. belladon. ♏$\frac{1}{2}$, tr. ginger, ♏v, pulv. opii $\frac{1}{4}$ gr.). In a compartment in the same case are nitrite of amyl pearls; opium and belladonna suppositories; pil. cath. comp., U. S. P.; and extra hypodermatic tablets; also a catheter and powder papers. The whole is arranged so compactly that the case is by no means uncomfortably large. With it, filled as indicated, almost any condition likely to be met with can be satisfactorily treated, or at least cared for until any further needed remedies can be brought at a subsequent visit. Most of the time I find it all I need; having, as I said, extra bottles of all of the sizes. I vary the contents as occasion may require, depending upon the season of the year and the prevailing medical fashion as concerns remedies. A word about administering remedies at the house: Tumblers and spoons vary very much, but sufficient accuracy with liquids and powders mixed in water can be attained by measuring in the glass to be used, with the spoon to be used, the desired number of doses, and then adding the medicine accordingly. This is quite as exact as the usual prescription label of a teaspoonful, no directions being given as to the size of the teaspoon. This measuring of the water in the glass does not take long and insures accuracy. Another thing that I have found of great help is to write out in full all the directions, with the exact hours when everything is to be given, especially in cases of acute illness. This makes a sort of calendar and avoids all chance of misunderstanding, and by having each dose as given checked, the physician can tell the next day at a glance just what has been done. The directions are written on a piece of powder paper, always in the medicine-case, so that no time is lost while the family hunts for paper, and the time required is very short. Powders are made sufficiently accurate in most cases without weighing, especially if they be weighed out a few times in one's office and an approximate idea of size and weight obtained. For surgical work I carry always ready, a bag with bandages, ether, gauze, and cotton, a syringe, and antiseptic tablets and powders. For obstetric work my armamentarium is that usually carried.

Marion, Mass.

PEROXIDE OF HYDROGEN IN DIPHTHERIA.

To the Editor of The Medical News,

Sir: The article "*In Re* Hydrogen Dioxide," by Dr. Wallian, of New York, in The Medical News of January 30th, reminds me of an experience that I had in December. This experience, while not resulting fatally to my patient, was quite alarming, and illustrates how, as a profession, we may be at the mercy of unscrupulous wholesale pharmacists. At the time I refer to I was treating several cases of diphtheria, using the peroxide of hydrogen, diluted one-half, as a throat-wash, applied by means of an atomizer. The results were good and the case of which I wish to speak particularly had almost recovered, there being but a slight remnant of a membrane on one of the tonsils, and this presented the rotten, swollen condition indicative of its speedy disappearance. At this time the retail druggist had just received a new supply of hydrogen peroxide—a fresh one so far as we could judge—and with some of this my prescription was refilled. This last supply was not from the same manufacturer as that we had been using, but was one of the most extensively advertised New York brands, put up in a long-necked bottle with space "necessary for expansion," as Dr. Wallian describes his sample No. 2.

After this had been used in the child's throat two or three times, the mother became alarmed at the effect and sent for me in great haste. Her attention had been called to the change in the medicine by the fact that the child would cry with pain whenever she would use the spray. Before this he had been quite docile. On examining the child's throat I found a very thin, grayish membrane covering the tonsils, uvula, and posterior pharynx, and around the edge of it in the mouth, the mucous membrane was reddened and angry-looking. On gargling my own throat, which was not tender, with the solution, I experienced a sharp burning sensation and my teeth were "set on edge" by the hyperacidity of the solution.

The membrane in the child's throat ran the typical course of a diphtheritic membrane, lasting, however, about a week. That the fresh invasion was caused by the irritation from the hyperacidity of the solution, I have no doubt, and I am strengthed in this belief by the fact that it ceased to extend as soon as the peroxide was withdrawn from the throat-wash, and by the fact that another case fared in a similar manner from the use of the same sample, although in this latter case the symptoms were not so alarming.

Now, I am thoroughly convinced from an experience in several severe epidemics, since its introduction, that

the peroxide of hydrogen is one of the most valuable, if not *the* most valuable, local agent we have in diphtheria, and I sincerely hope that an agitation against the sale of an impure article may touch the stony heart of the pharmaceutic chemist, so that we shall neither have to abandon this useful agent, nor prescribe it with fear and trembling that we may do the little sufferer from diphtheria more harm than good. I know that it is rather an unstable article, but I also know that some samples are harmless and do their work well, while others may be deadly in their effects on a child suffering from diphtheria. Respectfully yours,

John R. Espey, M.D.

Trinidad, Col.

UNTOWARD EFFECT OF CODEINE.

To the Editor of The Medical News,

Sir: A recent editorial in The News and a paper by the writer, "The Prevention of Morphinism," read before the American Medical Association, May 6, 1891, in which codeine is commended in lieu of morphine, make pertinent an added statement regarding it.

From proof at hand, there is reason to think that codeine will have a larger place in professional favor than it has had, and in order that its good repute may not be lessened, an incidental effect, several times observed during a large and satisfactory experience with it, may well be noted. This effect, it is quite proper to say, has been seen only in ex-morphine and ex-chloral habitués, but it is fair to presume that a like idiosyncrasy will, at times, be met with among those not addicted to either drug.

The first case was that of a druggist taking several grains of morphine daily, to whom I gave twelve grains of sulphate of codeine in one dose by the mouth, as a substitute for four grains of morphine. In less than half an hour he began to complain of great general itching; his face swelled until one eye was quite closed; his hands were puffed until he could not shut them, and his body—notably the back—became covered with large scarlet patches. There was no disturbance of brain, heart, or lungs. Most complaint was made of the itching. Prompt relief of this was brought by fluid extract of witch-hazel freely applied, and, with the redness, it soon subsided, but the swelling of the face and hands persisted for five days. There was no desquamation.

Since then I have seen four others—three, females—treated with doses from 1⅓ grains subcutaneously to 2 grains by the mouth, with the same, though much milder result. As in the first case, the itching was most complained of, and a peculiar feature of this was that it began in the head. There was no redness. The man's face was somewhat swollen. In all, the hamamelis worked well.

Lewin, in his *Incidental Effects of Drugs*, makes no mention of codeine, but cites a striking case of similar result from morphine in a man: "The eyelids were swollen, the whole face edematous and red, and wheal-like prominences appeared on the hands and other parts of the body."

Codeine possessing one-third of the power of morphine, it usually need not be given in doses larger than from ½ to 1 grain subcutaneously, or double that by mouth, so that, except in very impressible patients, effects such as I have noted are not to be expected.

It need only be added, that care is called for in these cases not to give too large doses.

J. B. Mattison, M.D.

Brooklyn, N. Y.

NEW YORK.

Castration as a Substitute for Capital Punishment.

At the last regular meeting of the New York Society of Medical Jurisprudence, held at the Academy of Medicine on Monday evening, March 14th, Gen. William A. Hammond, M.D., of Washington, read a paper entitled "A New Substitute for Capital Punishment and Means for Preventing the Propagation of Criminals."

Dr. Hammond began by stating that the primary object of all punishment for crime is the protection of society. Punishment should be of such a character as to act as a deterrent to crime to the utmost extent. Statistics, as well as the experience of all ages, show that the fear of the punishment of death has never prevented man from injuring society. Imprisonment for life has proven even less of a deterrent than death. This last form of punishment is not so terrifying to the criminal; there is always the hope of a chance to escape or of a pardon. The objects to be accomplished by punishment of crime are threefold: First, it should act as an example to others. Second, by placing the perpetrator in such a position that further infringement of the laws will be impossible. Third, by inflicting such an amount of mental and bodily suffering upon him that he will experience a lively sense of his crime; and hence, when he has incurred that punishment, he will be less prone than before to repeat his offence.

It is clear that to accomplish all the objects for which punishment is intended, neither death nor life-imprisonment are satisfactory, and some other means must be sought for. This method, Dr. Hammond stated, we have in a punishment which even in our own time and in this country has been occasionally employed for certain crimes—namely, castration. From a very early period castration was inflicted for adultery and rape. It has been in vogue in certain European countries, and not many years ago several negroes in Missouri were punished in this way for committing rape upon a white girl. The speaker said he would only refer to castration as a punishment for murder, and that his object was simply to show that this form of punishment would prove more deterrent than capital punishment or imprisonment for life; that it would entirely remove the man from the criminal classes, and that it would prevent the propagation of criminals.

1. Castration as a deterrent to crime. A man places greater value on his generative powers than on his life. As a French writer has said, "the dignity of a man resides in his testicles." When they are removed there is a marked change in the man. He cannot open his mouth without exposing his condition. The facial expression becomes altered. The man becomes cowardly and effeminate. It leaves a stain upon him worse than that

placed upon Cain. Dr. Hammond stated that the three negroes who were castrated in Missouri uniformly expressed a preference for capital punishment. He has several times put the question to criminals under sentence of death, and they all said they would rather hang than be deprived of their testicles. Juries that now hesitate about inflicting capital punishment would be less squeamish about castration. It would be a continuous punishment. It is not the intenseness of pain that has its greatest effect, but its continuance.

2. Castration would have the effect of making the criminal of some use to society. A dead man is of no use to society, and a man in prison is almost as bad. There are many occupations that would be open to him; he could occupy any position in which boldness or originality are not essential. Possibly he might make a good clergyman. He would not make a soldier, or a sailor, or a policeman, but he could edit a mild newspaper or make an efficient member of the legislative body. The value of eunuchs as singers has long been known. They would make excellent dry-nurses and safe type-writers.

3. Castration is probably the most powerful agent we have that will so alter the physical characteristics of a man as to remove him from the criminal classes. We can learn a great deal of the effects of the operation by performing it upon the lower animals. After it is done the fierce ram becomes mild and the cat ceases his nightly raids. So far as the human species is concerned, our observation is largely limited to the Orient, to those who have suffered from wounds or disease of the organs, and to those upon whom the operation has been performed for punishment. The universal testimony of persons who have travelled in Eastern countries is that the operation takes away all the dangerous elements that are present in the person; they become mild and obedient; they delight in the care of young children. It is true, however, that it causes a degradation of the moral as well as the physical qualities.

Dr. Hammond said that ten cases of castration have come under his notice. Three were the negroes who were punished in that manner for rape; two had lost their testicles as the result of disease; one had them removed as a possible cure for epilepsy; one had mutilated himself during an attack of delirium tremens, and three had been shot in battle. All these men were materially changed, and, what is more remarkable, all of them who were in the habit of taking alcoholic liquors lost their appetite for it. Castration probably produces a profound change in the brain-structure. As a reformatory agent, it stands unequalled by any other radical act we have.

4. As a means of preventing the propagation of criminals, it is as sure as death itself. If this form of punishment had been adopted a few hundred years ago, many thousand acts of crime would not have been committed. It is less cruel than capital punishment, more efficacious than imprisonment for life.

The scope of this paper has been restricted to the male sex. Women have become so accustomed to removal of the ovaries, and these organs are so much less essential to womanhood than the testicles are to manhood, that it might be necessary to substitute imprisonment for life in their case. Female murderers, however, are much less common than male, so that the matter is not of great importance.

Dr. Hammond concluded his paper by stating that he did not expect to see this measure adopted during his lifetime, or during that of any of his hearers. It is so radically different from the method that modern society has seen fit to establish that its adoption will take a long time. It took thousands of years to abolish torture and make other changes in the laws, and he felt sure that the method of dealing with criminals he had advocated in his paper would be more humane and efficacious than the one now employed.

In the discussion that followed the reading of Dr. Hammond's paper, Dr. Landon Carter Gray stated that the suggestion was so novel that he was rather taken aback. Any method that would prevent the propagation of the criminal class is certainly worthy of attention. The point he wished to criticise in Dr. Hammond's paper was that it had not been shown conclusively that castrated males will not commit acts of violence. It is reported that many crimes are committed in the harems in the East; what part the eunuchs played in these he did not know. In females ovariotomy has been done on an exceedingly liberal scale in late years, and it does not seem to eliminate their sexual characteristics.

NEW ORLEANS.

To the Editor of THE MEDICAL NEWS,

SIR: The Louisiana State Medical Society will meet in this city on the 26th of April. Until this year there did not seem to be much interest in the meetings, but this one will probably have a large attendance, as several questions of importance will come up. The most important will be the bill to regulate the practice of medicine in Louisiana. This bill is very similar to the one that was presented four years ago, but was then defeated. Some of the items of the proposed bill are as follows:

"That after the passage of this Act any person before entering upon the practice of medicine, in any of its branches, except dentistry, shall present to the Board of Medical Examiners a diploma from some medical college in good standing, and he shall present himself before the Board for examination upon the following branches, viz.: anatomy, physiology, chemistry, and the general principles of medicine and surgery, but without reference to any sectarian school or special dogma or doctrine.

"That immediately upon the passage of this Act, the Governor shall appoint six graduated physicians, one from each congressional district of the State, as a State Board of Medical Examiners, whose duty it shall be to examine into the qualifications of all applicants for permits to practise medicine in any of its departments, in accordance with the foregoing sections of this Act: Provided, that at all times not less than one-half the members shall be appointed from a list of thrice as many names furnished to the Governor by the State Medical Society.

"That any itinerant vender of any drug, nostrum, ointment, or application of any kind, intended for the treatment of disease or injury, or who may, by writing, print, or other methods, profess to cure or treat disease or de-

formity by any drug, nostrum, manipulation, or other expedient in this State, shall, if found guilty, be fined in any sum not less than twenty-five ($25) dollars and not exceeding one hundred ($100) dollars for each offence, to be recovered in an action of debt, before any court of competent jurisdiction, or shall be imprisoned for a term of not less than ten (10) days or more than thirty (30) days, or be both fined and imprisoned.

"That any person shall be regarded as practising medicine, in any of its departments, within the meaning of this Act, who shall append the letters M.D. or M.B. to his or her name, or repeatedly prescribe or direct, for the use of any person or persons, any drug or medicine or other agency for the treatment, cure, or relief of any bodily injury, infirmity, or disease. This Act shall not apply to dentists or midwives in the legitimate practice of these branches, nor to farmers and planters when exclusively practising, without compensation, on their employés in emergencies."

The new out-door clinic buildings of the Charity Hospital will be opened on the 5th of April. Heretofore the out-door clinic, amounting to more than 14,000 cases annually, has been treated in the wards.

One frequently hears of an effort to do away with the so-called "society practice" here, but it is not probable that it will be done, as there are many men here who seem to care but little for their own interests or those of the profession. This society system is in many ways a peculiar one. A party of men form a society, the dues of which are small. They engage a physician to do their work for an absurdly small fee, in some cases not amounting to more than a dollar a year for a member and his family. The member has a right to call the physician as often as he wishes, and frequently calls him when it is unnecessary. Many of the profession are very much opposed to this system and have tried several times to stop it, but have not been successful. It is to be hoped that the next will be a successful effort. The people who belong to these societies are laborers, of whom many could easily pay a fair fee. W.

NEWS ITEMS.

In Memory of Dr. D. Hayes Agnew.—At a regular meeting of the Philadelphia County Medical Society a minute relative to the death of Dr. D. Hayes Agnew was adopted, and a committee of ten members was appointed to represent the Society at the funeral.

At a special meeting of the College of Physicians of Philadelphia, called for the purpose of taking action in connection with the death of Dr. D. Hayes Agnew, eulogistic remarks were made by the president, S. Weir Mitchell, by John Ashhurst, Jr., and by W. W. Keen. A minute offered by Dr. Charles J. Stillé was adopted. It was agreed that the College should attend the funeral in a body. The president was authorized to appoint a Fellow to prepare a memoir of Dr. Agnew.

The funeral of the distinguished surgeon, teacher, and author was held amid impressive ceremonies on Friday, March 25th.

The Medical Society of the State of Pennsylvania will hold its forty-second annual meeting at Harrisburg May 17, 18, 19, and 20, 1892. Dr. J. H. Musser, of Philadelphia, will deliver the Address on the Practice of Medicine; Dr. T. D. Davis, of Pittsburg, the Address on Surgery; Dr. H. G. McCormick, of Williamsport, the Address on Obstetrics; Dr. J. W. Phillips, of Clifton, the Address on Mental Disorders; Dr. G. R. Rohrer, of Lancaster, the Address on Otology; Dr. A. A. Woods, of Erie, the Address on Hygiene.

Dr. H. A. Hare, of Philadelphia, chairman, will present the Report of the Committee on Pharmacy; Dr. J. A. Lippincott, of Pittsburg, chairman, the Report of the Committee on Contagious Ophthalmia; Dr. W. Murray Weidman, of Reading, chairman, the Report of the Committee on the Rush Monument Fund.

Addresses of Ophthalmologists Desired.—The Editor of THE MEDICAL NEWS wishes to obtain the addresses of all ophthalmic surgeons or physicians especially interested in ophthalmology residing in the United States and English-speaking countries of this continent. Please use postal cards addressed to this office, the word OPHTHALMOLOGIST accompanying the address.

Kitasato, who for six years has been pursuing studies at the Hygienic Institute, at Berlin, has been called to Tokio to assume the direction of a bacteriologic-hygienic laboratory soon to be opened.

THE RELATION OF BACTERIA TO DISEASE.[1]

BY HENRY C. CROUCH, A.M. (YALE), M.D. (GIESSEN, GERMANY),
OF COLORADO SPRINGS.

IN the evolution of modern scientific thought it is interesting to observe how many of the theories deduced from the exact methods of research and the careful experimentation of to-day, seem to have been anticipated in the speculations and conceptions of past ages. The atomic theory of matter that is at the basis of those most exact of modern sciences, chemistry and physics, was apparently already contained in the teachings of Democritus. The germ-theory of disease is almost of equal antiquity, and the latest investigations in modern bacteriology indicate the development of certain views that seem like the rehabilitation of the humoral pathology of the past, with its crases and dyscrases, its humors and its diatheses. I say advisedly *seem*, for on closer examination, although the superficial resemblance is obvious enough, the difference is greater and deeper. For vague conceptions and metaphysical speculations are substituted definite ideas, fixed laws, and determinate relations. But especially in the limitations of the modern theories, and the coëxistence of apparently contradictory, but in reality mutually explanatory natural laws, is this difference the most striking. Especially is this so in the field of medicine. The advance in late years has been immense and rapid; but the very nature of modern methods carries with it the condition that, to be intense, investigation must be limited in its scope and narrow in its field. It is not strange, then, that investigators themselves, under the vivid impression of newly discovered facts in their particular province, sometimes partake of this narrowness, and, extending their deductions beyond legitimate limits, deny the existence of what had seemed to past observers well-established clinical facts, and oppose dogmatic dicta to conservative prejudices. Such, for instance, has been the attitude of certain bacteriologists toward the doctrine of the heredity of pulmonary tuberculosis. However, in casting overboard the rubbish and lumber of past generations, it has often been necessary to rescue valuable truths, apparently contradicted by newer discoveries, and to restore them to the former position to which further research and wider knowledge again assigns them. And thus, I think, the developments of the last months in bacteriology will explain some of the contradictions between clinical observation and laboratory deductions. It is these currents in bacteriologic investigation to which I alluded in speaking of the apparent rehabilitation of the old doctrines of the humoral pathology; and I would like to select from the results of the immense labor of the past few months some of the more striking facts, and endeavor, in crude outlines, to construct a picture of the present position of bacteriologic science in its bearing on the causation of disease.

The introduction by Koch of his gelatin-plate methods marks a distinct epoch in bacteriologic investigation. It may be compared in its effects to the invention by Sims of his speculum. Apparently nothing more than an improvement in the purely technical part of investigation, it alone has rendered possible the great achievements of modern bacteriology. By its application, in connection with the improvements introduced by other workers in this field, it was shown that certain diseases were always connected with the presence of certain microörganisms; that these presented certain peculiarities in reaction toward certain stains, in their growth in cultures, and in other ways by which they could be distinguished from other apparently perfectly similar forms; that by inoculation with these cultures the disease could be reproduced in animals, or even in man—that is, that those microörganisms were specific for certain diseases, or, in other words, were their cause. In the enthusiasm excited by these discoveries, investigation was naturally directed to the detection of new pathogenic organisms, their classification and life-history. This may be called the morphologic period of bacteriology. As is the case with all methods, however, the time arrived when the results began to become more meager. Arrived at this point, investigators began to review the work accomplished, and, having proved that certain diseases were due to certain specific bacteria, a new question began to force itself on them, and demand their attention. This question was: *How* is the microörganism the cause of the disease? With the asking of this question it began to be realized that the greater part of the task was yet to be accomplished, and bacteriology entered on the second stage, which I would term the bio-chemical.

[1] Read before the El Paso County Medical Society.

This stage, fraught with the most wonderful possibilities for the recognition, the prevention, the cure of some of the most destructive and deadly of diseases, by the application to therapeutics of the knowledge gained by these investigations, demands our recognition and attention.

Life is the expression of chemical changes in the organism. Substances are introduced from without, undergo various changes, and the results of these changes are finally ejected from the organism in the form of bodies, infinite in number, complex in constitution, and varied in their properties. The undue retention of these products in higher organisms is accompanied by serious injury to the organism itself. By analogy, then, the metabolic products of bacterial life might be important, or even chief factors in the production of disease in the organisms in which they have their parasitic existence. It had been shown that by the introduction of pure cultures of a specific bacterium into an animal, the particular disease could be reproduced with almost mathematic certainty. If, now, instead of the microbe, the metabolic products, entirely separate from the microbe itself, be introduced, these, if they are the important factor, should reproduce the symptoms of the disease. This has been found to be the case. In illustration, we will take diphtheria. It has been proved, beyond doubt, by repeated and careful investigation, that the majority of cases of real diphtheria, and especially those of a malignant nature, are due to a peculiar microphyte called the Klebs-Löffler bacillus, found in the diphtheritic membrane. In 1888 Roux and Yersin published the results of their experiments in this direction. Having cultivated the bacillus in bouillon, and having tested in animals the virulence of the culture containing the bacilli, they proceeded to filter the bouillon through the porcelain cylinders of the Chamberland-Pasteur filter. Animals inoculated with the clear filtrate thus obtained, which was also shown by further tests to be entirely free from germs, developed all of the symptoms of diphtheria, including the characteristic paralyses, in the same manner as when subjected to inoculation with cultures of the virulent bacilli. Here, then, we have a case in which the metabolic products of bacteria, introduced into the system and circulating through its channels, are undoubtedly the chief factor in the disease. Accordingly, our attention must be directed to these products of bacterial life; they must be isolated, as far as possible, and examined with reference to their effects on animals; their course and ultimate fate in the organism must be ascertained; the means of defence which the organism possesses are to be studied, and methods for assisting these, or in other ways combatting the poison, must be invented—a task the magnitude of which can only be conceived when we realize how inadequate are our means of investigation, and how complex and elusive the substances to be examined. Let us, however, see what has been accomplished. First, let us examine what has been ascertained regarding the metabolic products of bacterial life.

Simple mention, without further discussion, may be made of some of the more familiar products, of subordinate importance from a pathogenetic standpoint. Such are carbonic acid, ammonium carbonate, the various fatty acids, and other products of fermentation and putrefaction, such as alcohol, various offensive gases, indol, skatol, trimethylamine, and the like. Of more importance are the various ferments that, independent of the bacteria themselves, are able to bring about striking chemical changes, and which are comparable to the digestive ferments, like pepsin and trypsin. It is possible, and even not improbable, that some of the deadly poisons to be referred to later may accomplish their work in a similar way.

Another class of substances, discovered in late years, and of immense importance and practical interest, are the leukomaïnes and ptomaïnes. Leukomaïnes are substances elaborated by bacteria, possessing certain distinct chemical characteristics, by which they can be arranged in a class by themselves. They are basic, form with acids crystalline salts of a definite composition, and give the chemical reactions of the alkaloids, and are similar in every way to the alkaloids of vegetable origin, such as quinine, morphine, atropine. Ptomaïnes is the term applied to such leukomaïnes as possess poisonous properties; and, in fact, certain of the ptomaïnes are among the most intensely poisonous substances known. Ptomaïnes are produced not only by pathogenic bacteria, but also by bacteria outside of the system, which, when introduced directly into the system, are harmless saprophytes. Such bacteria thrive in decomposing meat, fish, milk, and the like, and the poisonous qualities of the ptomaïnes generated therein have been only too often demonstrated by involuntary physiologic experiments. It is worthy of note that these substances are usually produced in the first stages of change, even before the meat may have developed that *haut gout* which some tastes demand, and are all the more dangerous on this account. As a familiar example of such ptomaïnes may be mentioned tyrotoxicon, which has been found in ice-cream, and has occasioned the development of severe toxic symptoms on various occasions. Further, it is probable that in the intestines substances of a similar nature are produced, and the absorption of these and other toxic bodies of like origin is in all probability the chief factor in producing the symptoms of cholera infantum, and,

when the invasion by a specific organism occurs, the symptoms of cholera Asiatica. In another class of cases, in which the microphyte effects its entrance directly into the organism, and grows and multiplies either in a limited portion, or generally diffused throughout the fluids and tissues of the body, ptomaïnes, or as they are more frequently termed under these circumstances, toxines, play a certain part in preventing the development of specific symptoms. Thus, in tetanus one of the active principles is a toxine called tetanine. This was first discovered, obtained in a pure state, and studied in reference to its toxic properties by Professor Brieger, of Berlin, to whose investigations our knowledge of ptomaïnes, as well as of toxalbumins, to be mentioned later, is principally due. Having thus discovered tetanine, and studied its properties by experiments on animals, he was able to demonstrate its presence directly in the arm amputated from a man affected with tetanus, and thus for the first time prove the occurrence of toxines in the human body.

The property of crystallization of the ptomaïnes and toxines greatly facilitates their investigation. It renders possible the isolation of these bodies in a chemically pure condition, and the study of the physiologic action of the pure substance. They can be analyzed, their empiric and rational formula can be fixed, and their chemical relations ascertained. Thus, for instance, cadaverin and putrescin, the names of which indicate sufficiently their places of occurence, have been found to be penta-methylene-diamine and tetra-methylene-diamine, respectively. It is not inconceivable that some of these bodies, or variations of them, may be found to possess therapeutic value.

The next group of substances that recent investigation has discovered among the metabolic products of bacterial life is one that has excited the keenest interest on all sides, for these seem to represent the specific poisons of various infectious diseases. They were termed toxalbumins by Professors Brieger and Fränkel, who were the first to isolate them and recognize their nature, and our knowledge of them only dates back to March, 1890, when the results of their researches were published. The name indicates their relation to the group of albuminous substances, and, at the same time, suggests the difficulties necessarily attending their investigation. As opposed to the crystallizable ptomaïnes and toxines, we have colloid, amorphous substances, which give certain of the reactions of the albuminoids, and which are exceedingly difficult to separate from one another, and to obtain in an approximately pure state. They appear, many of them, to be extremely unstable, and to break up during the ordinary and most careful manipulations. And it is doubtful whether the substances so far obtained, representing the purest and most active preparations, may not be largely composed of inactive albumoses, to which small amounts of the really active principle are either chemically or simply mechanically attached. This is one of the many problems awaiting solution by future investigators.

In the researches of Brieger and Fränkel already referred to, special attention was devoted to the specific poison of diphtheria. They succeeded in isolating a toxalbumin which, introduced into the system of guinea-pigs and rabbits, produced the same effects that Roux and Yersin obtained from the sterile infiltrate containing the various products of the vital activity of the Klebs-Löffler bacilli. This toxalbumin has been further studied by Wasserman and Proskauer, in the Institute of Hygiene in Berlin, and the results of their investigations were published in the *Deutsche med. Wochenschrift* last April. A description of the methods employed, and the results obtained, will give a very good idea of the present work in this line. The diphtheria-bacilli are cultivated in ordinary meat-water bouillon, with the addition of 1 per cent. of peptone and ½ per cent. of salt. Cultures about three weeks old were filtered through porcelain filters, and the filtrate, of which the absolute sterility had been determined by further tests, was concentrated to about a tenth of its volume, in a vacuum evaporator, at a temperature of about from 27° to 30° C. This concentrated filtrate was then freed as far as possible from peptones and globulins by dialysis with distilled water three times for twenty-four hours each time. The peptones and globulins thus obtained were found to be non-poisonous. The fluid remaining behind in the dialyzer was filtered until it was clear; to the clear filtrate thus obtained was added ten times its bulk of from 60 to 70 per cent. alcohol, and then allowed to stand twenty-four hours. This was then filtered, and the precipitate which had formed was collected on a filter. The diluted alcohol, being allowed to drop into absolute alcohol, gave a precipitate which, having been found harmless, we will ignore. The other precipitate which had been produced by the diluted alcohol, and then collected on a filter, was dissolved in a small amount of water, and the solution then treated with double the amount of a saturated solution of ammonium sulphate, to free it from peptones. The precipitate thus formed was re-dissolved in water, freed by dialysis from the ammonium sulphate, and then again treated with absolute alcohol. This procedure of dissolving in water and precipitating in alcohol was repeated until the solution in water was perfectly clear, whereupon it was again precipitated by means of the alcohol, and the precipitate thus obtained was dried at 37° in vacuo. The substance thus obtained was a fine white powder, perfectly soluble in water,

and the solutions gave the typical reaction of the albuminous substances.

The injection of 10 milligrams, *i. e.*, $\frac{1}{6}$ grain, of this substance caused the death of rabbits in from three to four days; of 5 milligrams, in two weeks; of 3 milligrams, after more than three months. The long time required before the death of the animals is very striking; they were sick during the whole period, wasted away, took little food, and often developed paresis of the extremities before death. Further experiments were conducted by the same authors to ascertain whether they could find the same substance in animals inoculated with the bacilli. In this they were also successful. In the bodies of rabbits that had succumbed to this infection, they could, by the same methods, obtain a similar white powder, which, however, proved even more virulent than that from the cultures, for 0.2 milligram, *i. e.*, $\frac{1}{300}$ grain, injected in a vein of the ear caused the death of a rabbit in fourteen days, with the development of the most typical symptoms of diphtheria in animals.

By similar methods Brieger had obtained a toxalbumin from the anthrax-bacillus, which caused the death of animals with the same symptoms as in those inoculated with the bacilli. And Immerwahr, in a communication last July, reports his experiments with a toxalbumin obtained from animals inoculated with the tetanus-bacillus, and further relates that he succeeded in isolating the toxalbumin from the leg amputated from a man suffering with lockjaw, and with it had inoculated five guinea-pigs, all of which died within forty-eight hours, developing typical tetanus.

Another class of albuminous substances of a poisonous nature is found among the peptones. Even the peptones resulting from normal digestion, when introduced directly into the circulation, were proved by Woolridge and Schmidt-Müllheim to act as poisons, and it seems that these, in passing through the intestinal epithelium, undergo modifications necessary for their further utilization. Some years ago, Brieger obtained from peptones a body possessing actively poisonous properties, which he called peptotoxin, but the fact remained isolated. In an article in the *Deutsche med. Wochenschrift*, of December 31, 1891, Hueppe gives an account of his work with the cholera-bacillus, and describes a body obtained from cultures of it under certain conditions, possessing all the properties of a peptone, and which apparently is the specific poison of cholera.

Allied to toxalbumins, but differing from them in certain respects, is another class of albuminous substances, about which comparatively little is as yet known. These substances, which are likewise poisonous, are not destroyed by high temperature—sometimes they will even stand repeated boiling. In certain cases, at least, they seem to be the active principle of vaccines that confer a more or less lasting immunity.

These various substances so far referred to, concerning many of which our knowledge is yet so limited, are all metabolic products of the vital activity of the bacteria. In addition to this, there is evidence that the dead bodies of the bacteria themselves, as distinguished from the metabolic products of the living bacteria, exert a certain influence on the tissues in which they lie. Thus, Buchner, having subjected cultures of various bacteria to prolonged boiling, separated the dead bacteria from their products, and, having treated the former with dilute caustic potash, obtained proteid substances that possessed marked chemotactic properties, and on injection into animals, brought about reactive inflammation, and even extended suppuration. Likewise, Prudden and Hodenpyl of New York, in their extremely interesting and able papers, in a series of skilfully and carefully conducted experiments along the same lines, have shown that when dead tubercle-bacilli, freed from all their metabolic products, are introduced into the circulation of rabbits, they excite at the place of lodgment a proliferation of the connective-tissue cells in the form of small nodules made up largely of epithelioid cells, and resembling exactly small miliary tubercles, but differing in the very important particular that they show no inclination to necrosis, caseation, or other degenerative changes, but do show a decided tendency toward conversion into connective tissue. In other words, the changes brought about are those that play an active part in spontaneous recovery from tuberculosis.

Having arrived here in our discussion, it seems a proper point for the consideration of Koch's tuberculin, although we are still ignorant of its actual nature. Probably, as at present constituted, it includes various of the substances already enumerated. Tuberculin is obtained from pure cultures of tubercle-bacilli, by extracting with a 4 per cent. glycerin solution, concentrating on a water-bath to, say, a tenth of the original volume, and then filtering. The strength is determined by physiologic experiment on guinea-pigs. Perfectly healthy animals are not greatly affected by moderate doses. Those, however, that have been rendered tuberculous by inoculation eight or ten weeks before, and have reached an advanced stage of tuberculosis, are extremely susceptible, and when a certain dose is reached, die in from six to thirty hours. Their dead bodies show certain characteristic appearances, by which their death can be shown to be due to tuberculin, and other accidental causes can be excluded. As most characteristic, Koch mentions the constant occurrence of numerous small hemorrhagic

spots, or ecchymoses, on the surface of liver and spleen. The strength of the tuberculin is so graduated that 0.5 gram is just sufficient to kill tuberculous guinea-pigs. After a long series of experiments, Koch has succeeded in obtaining from tuberculin a substance that is fifty times stronger, and which he regards as the active principle in an approximately pure state. This is a grayish-white amorphous powder, soluble in water, and giving various reactions of the albuminoid substances. Koch considers it as belonging to a class of albuminoids differing from any yet known, and believes that homologues will be found among the products of other pathogenic bacteria. The purified tuberculin thus obtained differs in no respect in physiologic action from the crude tuberculin, and thus Koch's hopes that a preparation might be found retaining the curative properties, and free from the other and evil effects, have not been realized. On the other hand, Klebs, of Zurich, who has been working on tuberculin supplied him by Koch, believes that he has accomplished this task. He claims that the evil effects of tuberculin, the violent systemic reaction, the fever, the necrosis, are due to the ptomaïnes contained in tuberculin, and that, by treating it with certain reagents that free it from these, he has found a substance that will bring about the destruction of the bacilli. According to him, patients treated with this purified tuberculin, which he calls tuberculocidin, improve rapidly, the various symptoms tend to disappear with remarkable promptness, the bacilli break down, lose their staining properties, and finally disappear. It will be noticed that the very point that, for Koch, is the test of the activity of his preparation—that is, the toxic effect on guinea-pigs—Klebs attributes to the action of ptomaïnes, and seeks to avoid. On the other hand, Koch evidently has no faith in the results claimed by Klebs, and believes that the substance obtained by the latter is merely an inert albumose. Prof. Klebs is a distinguished pathologist and bacteriologist, and a fuller description of his work and his therapeutic experiments will be looked for with great interest, especially as certain British investigators, particularly Hunter, have arrived at similar views respecting the constitution and action of tuberculin. But the evident skepticism of Koch, and of Brieger, who has been aiding Koch, together with the disappointed expectations attaching to tuberculin hitherto, certainly will moderate the hopes that Klebs's announcement might otherwise have excited. On the other hand, it must be emphasized that tuberculin is by no means the utter failure that many are inclined to assume. It has been conclusively proven that it has the power to arrest tuberculosis in guinea-pigs and rabbits; and even in human beings evidence is not wanting of a curative power, although this, in the majority of cases, is more than counterbalanced by its destructive effect as ordinarily used. I am convinced we have reason to hope that the untiring zeal of the many investigators now seeking the solution of this problem will discover the modifications or the changed conditions necessary to accomplish in man the results obtained in the animals mentioned.

The non-realization of the expectations raised on the introduction of tuberculin tended to bring about a certain reaction, and in the minds of the unthinking to cast discredit on the etiologic connection of tubercle-bacilli with human tuberculosis. And yet reflection must show, on the contrary, that it would really be an additional link in the chain of evidence, were such necessary. Comparatively large doses are borne by healthy individuals, or by those suffering from other diseases, without great discomfort; and yet in individuals in whom there is even the beginning of tuberculous trouble, minimal doses bring about a violent reaction. What could more plainly establish the peculiar relation between this product of the growth of tubercle-bacilli outside of the body and tuberculosis of the human subject?

Tuberculin is, in many senses, a remarkable substance, and particularly so in its elective action on tuberculosis. Recently, however, Kalning, in Riga, succeeded by the same process in extracting from the glanders-bacillus a similar substance, which, injected in healthy horses, had but little effect; but in horses affected with even the first beginning of glanders, caused a violent reaction. Kalning was a martyr to his scientific zeal, for he died from glanders contracted in his studies; but his work was continued by others. The substance called mallein has been shown to be an invaluable reagent for the detection of glanders in its earliest stages, and offers a valuable means for stamping out this disease.

We have up to this time considered the one side of one subject—the bacterial side. But bacteria are not the disease, nor are the agents with which they accomplish their effects on the organism the disease. The reaction of the diseased individual corresponds more properly to this conception, and the organism affected demands our attention, if we are to properly discuss the subject. Do not let the bacilli make us forget the cell, was the timely warning of Virchow, the creator of cellular pathology. And attention having been turned in this direction, many remarkable facts have been brought to light by recent investigation. I fear I have already exceeded the appropriate limits of a paper for this occasion, and I shall not be able to do justice to this side of the question. The subject of chemotaxis, and its importance, is very clearly treated in the papers of Prudden, already mentioned; and in

the Croonian lectures delivered by Burdon-Sanderson the same subject is discussed, and likewise Metschnikoff's doctrine of phagocytosis—a doctrine that, by the way, in crude outlines appears to have taken a vigorous hold on the lay imagination, but the importance of which seems greatly lessened by recent investigation. Of much greater importance is the toxic power that the blood has been shown to possess on most forms of microphytes. It is a singular circumstance, and one suggestive of the all-absorbing power of certain directions of research, that this fact, although known for some years, should not sooner have excited the interest of investigators that its importance deserved. In the last three or four years, however, many remarkable and important facts have demonstrated that just here lies the field for the practical application to therapeutics of the knowledge accumulated by bacteriologic research. It has been shown that blood has a directly destructive effect, not only upon most pathogenic organisms, but also upon their toxic products; it was next demonstrated that this power resided in the serum of the blood as opposed to the morphologic elements; and, finally, that it was due to certain proteid constituents of the serum, as yet not more definitely known. Thus, in the struggle for existence, the organism combats the microphytes with their own weapons.

It has been shown that the destructive action of the blood on these parasitic organisms is decreased by conditions of malnutrition and by surroundings unfavorable to the most healthy development. Here we have what suggests the *rationale* of our modern treatment of pulmonary tuberculosis. By improving the nutrition and placing the patient in the most favorable hygienic conditions, we increase the toxicity of the blood for the tubercle-bacilli. It has been further ascertained that the blood is not equally toxic for all microbes, and that the blood of different animals differs in this respect; in certain animals it is toxic for certain pathogenic bacteria, which are not affected or are influenced in a less degree by the blood of other animals. And this brings us to the subject of immunity. Why are some animals affected by certain diseases from which others are exempt? Why are individuals who have passed through certain diseases immune from these diseases for the future? Why does inoculation of man with a certain disease of the cow render him less susceptible to a disease that otherwise might attack him? We may now confidently assert that this is due to a certain constitution of the blood.

I should like to call your attention to some of the facts relating to this subject. In considering a problem, all that simplifies facilitates a solution. From this point of view a very brief description of a few recent experiments by Ehrlich, to whom we owe so much suggestive work, is, I think, adapted to throw some light on this subject. The difficulty of obtaining bacterial toxalbumins in a pure state and in sufficient quantity suggested to Ehrlich the idea of taking toxalbumins of vegetable origin, of which recent pharmaceutic research has discovered a number. One of these—ricin—the toxalbumin of castor-oil beans, is an intensely poisonous body, of which, judging from experiments on animals, 3 grains would be sufficient to kill an adult man. Guinea-pigs are so peculiarly sensitive to this poison that 1 gram, *i. e.*, 15 grains, would be sufficient to kill 1,500,000. Ehrlich took as the subject of his experiment white mice, and by feeding them very small doses, and then increasing the dose and injecting it hypodermatically, he was able in twenty-one days to inject four hundred times the amount of the dose originally poisonous, and later to increase it to one thousand. In other words, the mice had acquired a certain immunity to the poison. Now comes the suggestive point. Ehrlich has ascertained that by mixing ricin-solution with five times its amount of the blood of animals possessing a high degree of immunity, the ricin loses its toxicity and causes no symptoms when injected into animals. Further, by injecting the blood of white mice rendered immune into the body of other white mice, he was able to confer a considerable degree of immunity, viz., forty times the original. The inevitable inference from all this is that the blood of immune animals must contain a substance that neutralizes and probably destroys the poison. This is likewise probably the explanation of the earlier experiments of Salmon and Smith, in this country, who were able to obtain immunity in pigs against pig-typhoid, by inoculating them with sterilized cultures of the specific microphyte; and of Chamberland and Roux, who rendered guinea-pigs immune from anthrax, or splenic fever, by filtering cultures of the anthrax-bacillus, and injecting the sterilized filtrate. In a more elaborate and systematic series of experiments, Behring and Kitasato have shown, in reference to tetanus and diphtheria, that it is possible with the sterile filtrate from cultures of these bacilli to render animals insusceptible to these diseases; that the blood of animals rendered insusceptible neutralized the poison of the toxalbumins; and that when the blood of immune animals is introduced into susceptible animals, the latter acquire immunity. And, further, the most suggestive point was their success in thus rendering guinea-pigs immune with the blood of immune rabbits, or, in other words, the transference of immunity from one species of animals to another. And Behring further alludes to certain results obtained, not as yet made public, indicating the possibility of isolating the active principle, or obtaining

it in a concentrated form. As, in diphtheria, the substance instrumental in bringing about the immunity seems, according to some recent investigations of C. Fränkel, to be a harmless albumose, the practical significance is almost startling.

That there is in the blood of immune animals a substance that may be termed an antitoxine, seems, in accordance with all of these investigations, established beyond doubt. This antitoxine is probably gradually developed, and only when it reaches a certain strength is the inhibitive effect apparent; but in certain diseases it would seem that when it reaches this point the effect is very rapid. Such is the case in diseases that terminate by a crisis, as pneumonia. And it is interesting to know that in pneumonia G. and A. Klemperer, of Berlin, claim that by the injection of from 4 to 6 c.c. of serum, taken at the time of the crisis, from rabbits inoculated with pneumonia-cocci, they are able to produce a critical fall of temperature in patients suffering from pneumonia.

Even more definite is the use of the antitoxine of tetanus, as described by Dr. Schwarz, assistant at the surgical clinic at Padua. He reports the cure of a boy, suffering from traumatic tetanus, by the injection of the antitoxine prepared from animals by Tizzoni and Cattani, and refers to three other cases treated by other Italian physicians with the same successful result.

I have attempted in the foregoing to give a rough outline of the present state of bacteriologic research in reference to disease, and to indicate some of the currents now agitating it. When we consider that, so far, our studies have been solely with the bacteria, and practically with only one division of these —the schizomycetes—we can recognize how much remains to be done. In only two diseases—malaria and dysentery—have organisms belonging to a higher form of life—the plasmodium and the ameba coli—been shown to be the probable cause, and our knowledge of these is of the scantiest. Until the plasmodium has been successfully cultivated outside of the body, little can be known of its biologic properties; and, as it is now considered probable that various other diseases—notably, the acute exanthemata—are due to similar organisms, our knowledge of the causation of disease presents great gaps. But what we have recently learned is immense in its suggestiveness, and the prospect opening before us of achievements in therapeutics, and the control of disease, of knowledge of the subtle processes of life, and the intimate mysteries of Nature, must, with increasing force, appeal to our imagination, rekindle our faith, and redouble our enthusiasm for our most peculiar and noble calling.

Carl Credé, the distinguished gynecologist and obstetrician, died recently at Leipzig, aged seventy-two years.

A COLLECTIVE INQUIRY CONCERNING INTUBATION.

By RICHARD B. FAULKNER, M.D.,
of Allegheny, Pa.

Intubation in diphtheria is not viewed with favor by most authorities. H. R. Wharton does not think intubation will supersede tracheotomy in diphtheria, and he thinks that it is not being as widely employed in these cases as it was a year or two ago. N. Senn does not approve of intubation for diphtheritic or any other form of septic laryngitis. Hunter McGuire says: "I have never tried intubation of the larynx in diphtheria. I have never heard of its being done in or about this city that the patient did not die. I had rather myself resort to tracheotomy."

To the question: Do you think that intubation will be able to hold its own as a resort in diphtheria? D. Hayes Agnew answered tersely, "I do not;" Thomas G. Morton, "No;" H. Tuholske, "I do not think so;" Louis Starr, "Not in severe cases;" John Ashhurst, Jr., "It will never supplant tracheotomy, and I am disposed to think that it will be less often resorted to in the future than it is at present;" A. C. Bernays, "I do not think that intubation will prove successful in diphtheria;" R. W. Lovett, "I do not believe that intubation will hold its own when contrasted with tracheotomy in severe cases of laryngeal diphtheria;" C. H. Mastin, "It has not stood the test, and I am certain it will fall into disuse. It has always appeared to me as a most unsurgical procedure, and one that I have always opposed."

The first strong criticism of intubation was by Symond (*Brit. Med. Journ.*, November 19, 1887), following the article of Macewen (*Brit. Med. Journ.*, July 24 and 31, 1880), the first of the present revival of the operation. In the late (third) edition of his work on *Operative Surgery*, Stephen Smith describes the operation of intubation, but refrains from any comment upon it. Dillon Brown (*Boston Med. and Surg. Journal*, 1891, page 437) is quoted as saying that "many of the tubes in use are badly constructed." In the ordinary tubes an artificial epiglottis introduces fresh sources of danger. Three sets of tubes are described: six for children, ten for adults, seven of large caliber for foreign bodies and false membranes.

The perplexities of the technique are well described by G. W. Gay (*Comparative Merits of Tracheotomy and Intubation*): "In young children the space in which the necessary manipulations take place is limited; the larynx is small, deep, and movable, and made more so by the struggles of the patient. If the parts are extensively infiltrated and thickened it is by no means easy to determine the different structures by touch." Extraction of the tube is even more diffi-

cult than introduction. Fifteen cases of permanent lesion, from laceration of the larynx during extraction, occurred in the practice of J. M. Bleyer alone within two years. Two cases of perforation of the laryngeal wall occurred in the practice of Joseph O'Dwyer, as related by Gay.

The glottic aperture varies greatly in children of the same age, and it is at times impossible to select a tube of the proper caliber. Hence, occasionally, the tube falls into the trachea and bronchi. In a case reported by Moll (*Annual Assembly of Belgian Laryngologists*, May 17, 1891), the child died from a tube becoming buried in the trachea. In another instance, in the practice of Bleyer, in the latter part of November, 1891, the tube fell into the trachea during an attempt at extraction, and was removed by tracheotomy, performed by Frederic S. Dennis. In two cases reported by Prescott and Goldthwait (*Boston Med. and Surg. Journal*, December 31, 1891), "the tubes were drawn into the bronchi." Both patients died. The presence of the tube diminishes greatly the normal caliber of the glottic aperture.

The death-rate in diphtheria in epidemics of average severity is 10 per cent. Three deaths of every four are occasioned by diphtheritic sepsis or exhaustion, the remaining one by diphtheritic laryngeal stenosis (Jacobi, monograph on *Diphtheria*, 1880). Accordingly, a quarter of 10 per cent., that is, 2½ per cent., of the whole number of cases admit of resort to intubation. O'Dwyer's claim of 29 per cent. of recoveries from intubation, means 29 per cent. of this 2½ per cent. Two and one-half per cent. being the number admitting of operation, it therefore requires forty cases of diphtheria to furnish one of stenosis. Based on this calculation, the fifty intubations performed in this (Allegheny) city, within the past six months, required 2000 cases of diphtheria. In 1890, Jacobi (*Internat. Med. Congress*, Berlin; paper "On Diphtheria in America") stated that the death-rate from membranous stenosis is not nearly so great as in 1880. Therefore, the number of cases now required to furnish fifty intubations would be considerably more than 2000.

Lennox Browne, in the recent (third) edition of his classical work on *Diseases of the Throat*, has written: "It is probable that, the laryngeal mirror not having been used in the majority of cases for the purpose of forming an exact diagnosis, the operation may have been performed for mere spasm."

F. E. Waxham uses the laryngoscope, in adults, to place and to extract the tubes. He says: "When done by one who is not an expert, intubation is the most brutal and unsatisfactory operation ever devised by man." Bleyer (*Internat. Med. Congress*, Berlin, 1890, "Report of 512 Intubations") states that "I cannot dwell too strongly upon the necessity of a forced or normal laryngoscopic examination before entering upon the operation." Without laryngoscopic examination it may, at least, be urged that the condition of the larynx is not proven. In Chicago, intubation is in the hands of laryngologists, and especially Ingals, Casselberry, and Waxham. The same holds true in Louisville—Cheatham, Pusey, Ray, and Dabney doing the work. Also in St. Louis the same rule holds true.

O'Dwyer has written that "The dangers of intubation are almost *nil*, but only so in the hands of an expert, and experts are not made in a week, or a month, or even a year—in fact, there are very few yet in existence. That intubation is easy is one of the delusions that still exist in regard to the operation." In the course of a debate upon intubation I heard a gentleman remark that "It is just as easy to pass a tube into the larynx as it is to pass a catheter into the urethra." As a comment upon that remark, Dr. O'Dwyer says that "Comparing intubation to catheterization of the urethra is nothing less than a crime, because it encourages everyone who has a case of croup to try it, often with the result of choking his patient to death."

In my neighborhood, lately, a child died and was buried with an intubation tube in its throat. I learned, later, that it was the common thing for those who died after intubation, to die and to be buried with the tubes in their throats. Popularity of intubation must be viewed with the gravest apprehension. The operation is dangerous, difficult, inferior to tracheotomy, and can never be depended upon. In many instances it is the literal truth that "life hangs by a thread." And when between this life and eternity a mere thread, any strand of which may be imperfect, is all that the surgeon can interpose, it shows the utter prostitution and the absurd extremity in the application of a noble art. No other operation seems, *à priori*, so in conflict with common sense. In the hands of the inexpert—and in this era of cheap medical colleges be it remembered that that genus is multiplying rapidly—the practice of intubation is the practice of manslaughter.

1. Under what circumstances occurring in diphtheria do you consider intubation necessary?

J. Lewis Smith: When there is that degree of dyspnea that the child is restless, and the suprasternal and infra-sternal regions recede during respiration.

2. In that class of cases in which tracheotomy has been considered appropriate, do you believe intubation to be a proper substitute?

J. Lewis Smith: It is a proper operation, and if the dyspnea is not relieved by it, or if it returns,

the presence of the tube does not prevent the subsequent performance of tracheotomy. E. F. Ingals: In all children under five years of age. J. Solis-Cohen: Not as a rule.

3. Do you think that in cases of diphtheritic membranous exudation we should always be prepared to perform tracheotomy?

Charles McBurney: Unquestionably. Waxham: Yes. Gay: Intubation should not be undertaken without having the facilities for tracheotomy at hand. O'Dwyer: Those with only a limited experience with intubation should be always prepared to do tracheotomy.

4. Is there, briefly, any serious objection to the performance of intubation which exists always in every instance of diphtheritic laryngeal stenosis, either inflammatory or membranous?

J. Lewis Smith: No; if the obstruction to the respiration causes suffering to the child, or any notable dyspnea. Ingals: No, providing it is done skilfully. Waxham: The difficulty of performing it. J. Solis-Cohen: Yes; the presence of pseudo-membrane, which may crowd down in front of the tube and occlude it. The absence of an attendant competent to remove the tube promptly in an emergency. Gay (This answer is interpolated chiefly from his article on the "Comparative Merits of Tracheotomy and Intubation"): Accidents are less common after tracheotomy than after intubation. While intubation is a most valuable operation, it is not so free from objections and complications as some of its advocates would lead us to suppose. It may not relieve the dyspnea; the tube may "gum;" may become suddenly occluded, and unless quickly ejected or removed, death will ensue; and there may be great difficulty in feeding the patient.

5. What do you consider the greatest objection to intubation in diphtheria?

D. Hayes Agnew: The probability of displacing false membrane and blocking up the air-passages. J. William White: Pushing membrane in advance of the tube; difficulty of feeding; plugging of the tube. John Ashhurst, Jr., C. B. Nancrede, Gay, Goldthwait: Difficulty of feeding. Wharton: Pushing membrane in front of the tube; difficulty of feeding. Louis Starr: The difficulty of feeding and the liability of food, especially liquids, entering the trachea through the tube and inducing pneumonia. The risk of the tube slipping into the trachea, or being coughed up and swallowed. The frequent non-success of intubation, subsequent tracheotomy becoming necessary, hence dangerous delay. Cheatham: A false passage; pushing of membrane; ulceration of larynx and trachea from pressure; food pneumonia. T. F. Prewitt: Pushing down of a mass of exudation into the trachea. H. Tuholske: Displacement of membrane; mechanical and continuous insult to part in a state of intense inflammation. C. H. Mastin: I am perfectly certain that the presence of the tube, in glottis and larynx, adds to the local irritation and favors ulceration. William Porter: The tube acts as a foreign body in a larynx already inflamed by disease. The current of air entering the lungs continues to pass through diseased channels. Henry H. Mudd: I believe it is a relief to the child and to the diseased throat to have the air come through the trachea tube, rather than through the diseased pharynx; difficulty of feeding. P. S. Conner: Difficulty in introducing tube; the danger of its slipping down, or being coughed out. R. W. Lovett: In contrasting intubation with tracheotomy the striking point is that when a tracheotomy tube is in place there is a tremendous discharge from it of mucus, pus, and detritus, which is continually coughed out. In intubation cases, there is little of this. It seems reasonable to suppose that this is because it is not raised so easily, and is drawn more into the lungs and bronchi in intubation cases. This seems to me a great practical objection to intubation. It has seemed to me that the percentage of pneumonia was high in the intubation cases that I have watched. In certain cases a dangerously rapid tracheotomy is necessitated by attempts to intubate. In my own experience, twice in the last month, after a careful intubation, the child has stopped breathing as soon as the tube was put in, and instant tracheotomy has been necessary to save life.

6. In desperate cases of diphtheria, accompanied by laryngeal membranous exudation, would you justify the resort to intubation equally or preferably to tracheotomy?

O'Dwyer: The only justification for tracheotomy as a primary operation, is the absence of some one competent to do intubation. Joseph D. Bryant, Cheatham, Waxham: Preferably. Smith, Ingals, Goldthwait, Gay, Bleyer, J. Ewing Mears: As a primary operation. D. Hayes Agnew: No; would resort to tracheotomy. Louis Starr: Tracheotomy; decidedly. John Ashhurst, Jr.: No; prefer tracheotomy. I feel that the patient is safer with a tube introduced through an opening below the larynx, than with one passing through the larynx itself. Lewis A. Stimson: My preference is wholly for tracheotomy. W. T. Bull: In a general way I have formed the conviction that intubation is not suitable for the grave cases. Charles McBurney: My experience is more with tracheotomy. J. William White: Do not consider intubation equal or preferable to tracheotomy. C. H. Mastin: I would not resort to intubation. I cannot convince myself that it is a judicious or proper operation. Tracheotomy is a rational operation. Tuholske: Tracheotomy is vastly superior to intubation. Wharton:

No; decidedly tracheotomy. T. F. Prewitt: Tracheotomy; decidedly. J. Solis-Cohen: All the cases in which tracheotomy is indicated do not do as well as by intubation. Thomas G. Morton: My experience with intubation has not been favorable. John B. Roberts, William Porter, John H. Brinton, A. C. Bernays, C. B. Nancrede, Henry H. Mudd, C. G. Jennings, Ernst, and Sajous: Prefer tracheotomy. R. W. Lovett: Much prefer tracheotomy. If I may quote from our Boston City Hospital figures, up to 1887 the recovery under tracheotomy was 29.05 per cent. in 327 cases. In 392 cases of intubation since that time the recovery is 20 per cent. and a fraction. As these two groups of cases were of the same class, treated in the same institution, by the same surgeons, for the most part, they give ground for the suspicion that in desperate cases tracheotomy saves more lives. My personal experience accords with these figures. ("The Boston City Hospital affords the best opportunity for the study of croup to be found anywhere in this country. When you shall have accumulated the same number of intubations that you have had tracheotomies, it will settle the question of the comparative merits of the two operations in saving life better than thousands of cases collected from other sources." J. O'Dwyer, as quoted by G. W. Gay.) In the comparison, while tracheotomy leads intubation by 9 per cent., observe that intubation starts with an advantage of a higher gross number on which to compute. Up to September 20, 1888, tracheotomy led intubation by only 5 per cent., in 327 tracheotomies, as against 107 intubations. Conant (*Boston Med. and Surg. Journal*, December 31, 1891): I have felt that intubation, which at the time it came out was claimed to have a percentage very much larger of recoveries than tracheotomy, was a thing which later on would prove to be fallacious, and the more cases of intubation that are reported the less has grown the percentage of recoveries. The recoveries from intubation are growing proportionally less every year at the Boston City Hospital. Up to January, 1890, the per cent. of recovery was about twenty to twenty-five, and then it fell to fifteen (Prescott).

A. Jacobi has abandoned tracheotomy. He has not performed intubation. From his plain talk (*Internat. Med. Congress*, Berlin, 1890; paper "On Diphtheria in America") it is evident he thinks more of mercurials than of intubation. "I learned that when the constitutional effect of mercury could be obtained speedily, cases of fibrinous tracheobronchitis got well in an unexpected manner." "During the last six years preceding 1888, I have seen no less than 200 cases, and amongst them recoveries have not been rare. In the practice of no less a man than O'Dwyer, I have seen two cases of general and laryngeal diphtheria in the same family which got well without any operative procedure." "I have never seen so many cases of tracheotomy getting well as between 1882 and 1886, when the bichloride was constantly used as detailed." "The beneficial effects of mercury are not limited to cases of stenosis, but apply also to those of sepsis." These remarks of Jacobi can be applied to the practice of many physicians in this community. I am gratified to add my testimony to his, for I know of cases of diphtheria now getting well under the mercurial treatment, small doses often repeated, to make the percentage of recovery from membranous laryngitis greater than ever before.

HYDATIDIFORM MOLE, WITH REPORT OF A CASE.

By J. E. McCUAIG, M.D.,
ASSISTANT PHYSICIAN TO THE STATE HOSPITAL FOR THE INSANE, DANVILLE, PA.

THE etiology and pathology of the so-called hydatidiform, or vesicular, mole is a subject that has always attracted the attention of the medical profession. In the infancy of the science of obstetrics it was believed that if the parts of the embryo and secundines were not separated and distinctly formed from the mixture of male and female semen, they formed a mass that, when discharged before the fourth month, was called a "false conception;" if it continued longer in the uterus, it was denominated a *mola*. Another theory advanced was that the growth was independent of conception, and was, in fact, a true hydatid, or acephalocyst, such as is formed in the liver, spleen, and other organs. In this connection Rokitansky (*Pathological Anatomy*) says: "Cysts are very rarely formed in the uterus; we have not met with a single example in Vienna, and I myself have only inspected one case of uterine acephalocysts."

The admission of this one case by such an authority is sufficient to establish the possibility of the occurrence, and raises a point of some considerable interest from a medico-legal point of view. To Cruveilhier is assigned the credit of first demonstrating that the hydatidiform mole is not due to echinococci, but is, in fact, a degenerated ovum. Velpeau traced the origin of the degeneration to the chorion, while the observations of Professor Robin showed that the envelope of the cysts is identical with the external membrane of the chorionic villi. The accepted theory of pathologists now is that the process is a proliferative degeneration of the villi of the chorion, and a hypertrophy of their investing epithelium and connective-tissue cells, which undergo mucoid degeneration. The pathology being such, it is to be regretted that this antiquated misnomer still clings to the affection,

and that it has not received a title more in accord with the process involved. Search for the primary cause of this degenerative process opens up a wide and interesting field, and one in which but little information can be gained.

Since the abandonment of the echinococcus as a causative agent, various theories have been advanced. Dr. Graily Hewitt (*Obstetrical Observations*, London) claims that the source of the evil is fetal, and not maternal; that instead of chorial disease causing disintegration of the fetus, the death of the fetus causes degeneration of the villi. This view of the case is supported by the clinical fact that in the case of twins one ovum may undergo degeneration, while the other may go on to full term, and a healthy, full-sized child be born. The contention, which if established would appear to support this view, that a retained portion of the placenta may undergo a similar degenerative process, has been disproven by clinical observation. Opposed to this theory, again, are the observations of M. Brechet, as quoted by Cazeaux (*Theory and Practice of Obstetrics*), who reported a case in which a few hydatidiform vesicles occurring on the placenta did not prevent the birth at term of a normally formed child of the usual size. The view perhaps most generally accepted, however, looks to a maternal influence as the causative agent, and this influence is thought by the greater number of observers to be the syphilitic or the carcinomatous dyscrasia. Lusk (*Science and Art of Midwifery*) says: "That the exciting cause of the hydatiform mole may be a morbid maternal condition is rendered probable by the repeated recurrence of the disease in the same patient, by its coëxistence with inflammatory decidual disease, or with extensive uterine fibroids. It has been found to be most frequent in aged and multiparous subjects."

The probable causes cited do not seem to me to account for the following case:

H., an imbecile, twenty-two years of age, unmarried, was admitted to the State Hospital for the Insane on September 28, 1891. At the examination, on admission, her temperature was found to be 98.5° F.; pulse, 84; tongue clean; and bowels regular. The patient was well-proportioned, and apparently in good physical health. There was no history of syphilitic or carcinomatous disease; a maternal aunt had died of pulmonary tuberculosis. Previously to admission, menstruation had been regular, and her general health good. She had led an immoral life, but had never conceived. A month after coming to the hospital she complained of "dyspepsia," with vomiting. Remedies directed to this indication soon relieved the symptoms. An attack of dysentery, which she had at this time, having left her in a weak and somewhat emaciated condition, and the appetite being capricious, she was given a tonic. As the menses had failed to appear since admission, an effort was made to improve the general health, but no direct medication was resorted to. On the night of January 3, 1892, I was called by the night nurse, who stated that H. was suffering severe pain in the bowels. When I reached her room I found that she had voided a mass that presented the characteristic cystic formation, and precluded any doubt that my patient had given birth to a hydatidiform mole, notwithstanding her assertion that she had passed a portion of her liver. Before my arrival the bulk of the growth had been expelled in two pieces, and at that time she was bleeding, though not profusely. I immediately passed two fingers through the os uteri, which was dilated to the size of a silver dollar, and swept the cavity of the uterus as thoroughly as I was able, removing a quantity of cysts and shreds of decidua. The uterus contracted tightly, and the hemorrhage, which had never been excessive, stopped. She was given a vaginal douche of carbolic acid, 1:40; and two days later, as the temperature had reached 103° F., and the pulse 130 beats per minute, the uterus was washed out with a solution of corrosive sublimate, 1:5000, followed by carbolic acid, 1:50, a few cysts and decidual shreds being removed; an iodoform pessary was inserted, and quinine sulphate, gr. v every four hours, administered by the mouth. To relieve the intense pain and tenderness over the lower part of the abdomen, hypodermatic injections of morphine sulphate, gr. ¼, were given and hot turpentine stupes applied locally. Under this treatment the temperature rapidly subsided, and the patient made a good recovery. The entire growth constituted a mass slightly larger than a child's head; the cystic degeneration was not complete, and the amniotic cavity was empty. No trace of a fetus could be found; evidently the process had begun shortly after conception.

The points of interest in this case, to me at least, are:

1. The absence of all the classical signs of the presence of a mole. There was nothing like a hemorrhage from the time of her admission till the birth of the neoplasm. No cysts were passed. The character of the institution renders exceptional facilities for making sure of these facts. The abdominal enlargement, usually disproportionate to the period of gestation, was so slight as to escape notice in a patient under observation for amenorrhea; there was no enlargement of the breasts. Owing to the mental condition of the patient no information could be gained as to the time of conception, and as she made no complaint and manifested none of the usual signs of pregnancy, the condition was not diagnosticated.

2. The lack of apparent cause for the degenerative process. The patient is young, a primipara, in good health until within a few weeks of delivery; and with the exception of one case of pulmonary tuberculosis, as stated, the family history shows no hereditary dyscrasia.

EXAMINATION OF SOME COMMERCIAL VARIETIES OF HYDROGEN DIOXIDE.

BY HENRY LEFFMANN, M.D.,
AND
WILLIAM BEAM, M.D.,
OF PHILADELPHIA.

HYDROGEN dioxide, generally inaptly called hydrogen peroxide, has found, in recent years, many valuable applications in preventive medicine and therapeutics. The pure article being very difficult to prepare and preserve, the commercial forms consist of dilute solutions in water, containing a very small amount of actual dioxide. Since the medicinal value of the article depends on its strength and freedom from impurities, it is important to make some comparative determinations on these points of the brands of hydrogen dioxide now offered in the market. The tests employed have been frequently described, and it will not be necessary to repeat them here. Among the impurities, free acid is the most objectionable, on account of its irritating action.

Comparative tests of commercial brands have from time to time been published in medical and pharmaceutical journals, but usually without indication of the identity of the samples, and, therefore, of but little practical value. In judging of the strength of any sample, the unavoidable liability to decomposition must be regarded. On the other hand, the proportion of free acid and of metallic salts will not be appreciably affected by the lapse of time.

In the following examination care was taken to secure fresh samples, and they were all in the original, unbroken packages when delivered to us. The proportion of hydrogen dioxide is expressed, as is customary, in volumes of oxygen, determined by the standard method with potassium permanganate:

Brand.	Volumes of oxygen.	Barium salts.	Earthy salts other than barium.	Acidity expressed in milligrams of KHO required for 25 c.c. of sample.
O. C. (Oakland Chem. Co.)	15.6	None	None	3.8
Béné	11.8	"	"	3.36
Lehn & Fink	10.5	"	"	4 08
Marchand (1st sample) .	10.1	"	Present	34.08
" (2d sample)[1] .	Not determined	"	"	22 00
Powers & Weightman .	9.02	"	"	23.04
Merck	12.09	"	Large amount	16.32
Mallinckrodt . . .	9.14	"	Traces.	8.64

[1] This sample was one that had been purchased for some laboratory experiments in bleaching, and, having been kept without any precautions to preserve its strength, the determination of the volume of O would have been of no value in indicating the original quality; but since the amount of free acid and earthy salts will not be affected by such treatment, they were determined. The volume strength claimed for the sample originally was less than that claimed for sample No. 1.

ORIGINAL LECTURE.

ENDOMETRITIS: UTERINE DILATATION AND DRAINAGE.

A Clinical Lecture delivered at the Medico-Chirurgical Hospital, February 2, 1892.

BY E. E. MONTGOMERY, M.D.,
PROFESSOR OF OBSTETRICS AND GYNECOLOGY IN THE MEDICO-CHIRURGICAL COLLEGE; OBSTETRICIAN TO THE PHILADELPHIA HOSPITAL; AND GYNECOLOGIST TO ST. JOSEPH'S HOSPITAL.

I PROPOSE to-day to consider the subject of dilatation of the uterus and the conditions that indicate it. We will first discuss the indications for dilatation and the advantages to be derived therefrom. In many cases the knowledge that we are able to obtain by means of conjoined manipulation and examination with the speculum, and in rare cases the introduction of the sound, will be insufficient to determine exactly the character and condition of the cavity of the organ. In such cases it may be necessary to examine still further to determine what is its condition and the lesions that give rise to certain symptoms that may be present. Such an exploration of the uterus will be indicated particularly when hemorrhage is a marked symptom. It is well to remember that hemorrhage may be due to a variety of causes: thus, for instance, to a diseased condition of the endometrium, which is known as hemorrhagic endometritis, in which the mucous membrane is swollen, its vessels distended, the surface abraded, the epithelium lost, and the capillaries so engorged and their walls thinned that they rupture easily. Not unfrequently we have papillary growths on the uterine mucous membrane, a condition such as I have shown you at different times during my clinical lectures, cases similar to the one on which we operated a week ago. These growths may extend from the uterus into the vagina, forming what is known as small granular, mucous, or vascular polypi; or they may be situated at any part of the uterine mucous membrane, and in some cases give rise to considerable hemorrhage.

Again, hemorrhage may be the result of inflammation in the structures about the uterus; thus, inflammation of the broad ligament on one side, in which extensive exudation occurs, may give rise to a passive congestion of the uterus and a resultant hemorrhage independent of any disease of the uterine mucous membrane, or in which such disease is secondary to that outside of the organ; in cases in which the ovaries have undergone what is known as cystic degeneration, hemorrhage is also a marked symptom. In such cases, notwithstanding everything that may be done in the way of local applications to the uterus itself, the patient will continue to bleed until the congestion is arrested by the removal of the offending organs.

Another source of hemorrhage, and one that should ever be kept in mind, is the result of degeneration of a malignant character of the uterine mucous membrane.

This, in the majority of cases, results from disease about the cervix, and, when so situated, is readily recognized by touch or examination through the speculum. There are cases, however, in which malignant disease of the uterus occurs, and the body is the seat of its development; this takes place in about 2 per cent. of the cases in which malignant disease is situated in the uterus. Again, hemorrhage may result from sarcoma situated either in the walls of the organ or in its mucous membrane. Probably the most frequent cause of uterine hemorrhage is the development of growths within the walls of the organ itself, which in their subsequent development are forced into the cavity. These growths are known as fibromata, or fibro-myomata. As such a growth develops and is situated near to the internal lining membrane, it is pushed into the cavity, taking with it a covering of the mucous membrane. The vessels in this mucous membrane become distended, their walls thinned, the epithelium lost, the papillæ become enlarged, points of ulceration are found, and hemorrhage of a serious character, often sufficient to endanger the life of the patient, may take place. In such cases, the hemorrhage is either an exaggeration of the menstrual flow, known as menorrhagia, or one that occurs indedently of it and known as metrorrhagia. The enumeration of these various conditions illustrates the importance of further examination in order to be able to determine exactly the cause of hemorrhage in an individual case.

The degree of dilatation will depend, of course, upon the purpose for which it is accomplished; if it is with a view of removal of the growths within the cavity of the organ, a greater dilatation will be required than simply for the exploration of the cavity for diagnostic purposes.

Independently of the indications for dilatation of the uterus for diagnostic purposes, the uterus is also dilated with a view to therapeutic effect—as when the uterus is flexed, or its canal is contracted as a result of congenital conditions, or from the existence of inflammatory trouble. Inflammatory conditions may be the sequelæ of either septic infection following parturition, or of long-continued catarrhal disease of the uterine mucous membrane. Again, dilatation may be said to be indicated in those cases in which endometritis has existed for a considerable length of time, has given rise to swelling of the mucous membrane of the outlet or cervical canal to such a degree that the drainage of the uterus is defective, and there is a constant tendency to regurgitation into the tubes, thus developing tubal trouble. Indeed, in the treatment of inflammatory diseases of the uterus, the first and prime consideration should be to secure thorough and efficient drainage. We need but to investigate the history of long-continued inflammation of the uterus to recognize the close association of tubal and ovarian disease.

The patient I bring before you to-day is a woman who is suffering from a disease that has been in existence for some length of time, and in whom I consider that the indication for dilatation of the uterus from a therapeutic standpoint is amply indicated. The woman has been married twelve years; she has one child, eight years of age; the menses are irregular, sometimes occurring every six weeks, and attended with pain in the abdomen and back, with headache, and followed by slight leucorrhea. She also suffers from constipation. Patients that have an inflammation existing in the mucous membrane of the uterus have not only pain at menstruation, but the pain usually occurs during the entire period, and in some cases, particularly when the inflammation has extended beyond the uterus into the tubes, it is likely to be followed by pain of a spasmodic character. The condition is due to the muscular contraction of the Fallopian tubes, in their effort to force out and carry the secretion into the uterus. In this patient we have the uterus contracted; the mucous membrane of the neck is so swollen that the discharges cannot readily make their exit from the organ, and the patient has to go into labor in order to rid the uterus of them. The result is that these discharges will oftentimes make their exit more readily into the tubes than through the cervical canal, and the result is a dilatation of the uterine orifice of the tubes, oftentimes of the tubes themselves, increased intensity of the inflammatory condition, and largely increased secretion. When women have suffered for a considerable length of time from uterine disease, it is exceedingly common to find that there is a diseased condition of the tubes and of the ovaries. This disease is secondary; partly a result of the defective drainage from the uterus and regurgitation of the contents into these organs, and partly from reflex effect upon the circulation. Supposing such a patient, with the pelvic organs in a state of irritation, falls into the hands of a physician whose routine practice is by touch to ascertain the presence of the cervix, introduce the speculum, and through it the sound. The result will almost certainly be a carrying of the infection into a soil ready for its nurture and development, and the occurrence of an acute attack resulting in tubal and ovarian trouble so serious as possibly to threaten the life of the patient. So frequently has this been the case, that some physicians have been led to condemn all local treatment as injurious and detrimental; have been led to deride and condemn any treatment directed to the inflamed surfaces of the uterine tract. The difficulty is not that a plan of treatment has been pursued, but that an improper one has been exercised. It is just as important to religiously adopt aseptic measures in the treatment of the uterine mucous membrane as it would be in the practice of abdominal surgery. Those who have condemned plans of treatment directed to the uterus, have rendered a service in directing attention to the danger resulting therefrom, and awakening in the minds of the profession the importance of most careful and proper procedures in treating such difficulties.

Instead of the presence of the conditions described contra-indicating uterine treatment, however, they should be considered as urgently demanding the appropriate measures, in order to prevent more serious trouble. Even though there may be ovarian or tubal trouble, by proper and judicious measures we may be able to arrest its further progress, and save the patient from the necessity of a sacrificial operation. Within the last two years I have operated upon a number of patients upon whom sacrificial operations had been advised, and have been successful in restoring them to health without the loss of their organs.

You remember, this patient gave a history of having had a child eight years ago, and we find that there is in her case some indication of tubal disease, as presented

by tenderness, by some thickening of the tube, the result possibly of distention and of peri-salpingitis. I propose to operate upon her to-day with a view of overcoming this condition and possibty saving her from a sacrificial proccdure. As a preliminary to this, we have had the alimentary canal thoroughly evacuated, the vagina has been irrigated with antiseptic solutions twice daily, and once every hour for the last three hours—this with a view of disinfecting, as thoroughly as possible, the vaginal tract, and particularly the discharges that take place from the uterus. It is important to remember, however, that irrigation alone will not entirely remove the débris, so that the vagina should be thoroughly swabbed or brushed with a disinfectant solution such as acid sublimate, or the peroxide of hydrogen, before the speculum is introduced and the operation begun.

The instruments have been as carefully prepared as if for an abdominal operation; the care and precaution in this direction really constitute the secret of success in all operations of this character.

With the patient under the influence of an anesthetic, before proceeding to the operation, I examine carefully about the uterus to determine whether the inflammation is too extensive to permit us to proceed safely with the plan we have in view. Finding the uterus to be movable —that, notwithstanding the thickening and enlargement of the tubes, they are not bound down—we shall proceed as intended. My object in examining carefully in this matter is, that we may not run the risk of having our patient infected from accumulations that are already within the cavity of the uterus, as in tubes distended with pus or other infectious material. The operation is performed as follows: We introduce a Goodell speculum for the reason that it may be made to dilate laterally or antero-posteriorly, and its blades are less in the way. The cervix is grasped with the volsella forceps and drawn upon sufficiently to straighten its canal, and the dilatation is begun by the use of graduated bougies. These instruments are so arranged that there is a bougie upon either end; the circumference of each bougie about two centimeters greater than the one preceding. It is astonishing how rapidly and safely, with instruments of this character, the cervical canal can be dilated, from an opening through which a very small instrument can be passed to one sufficiently large to permit the introduction of the finger. I prefer the bougies to the ordinary parallel dilators, for the reason that the pressure is made upon all parts of the uterus equally, and there is less likelihood of tearing. Then, too, in the bilateral dilatation, the pressure is made entirely upon the sides of the uterus, which gives rise to severe bruising and subsequent danger of a slight slough that may lead to the infection of the cavity of the uterus. After the dilatation of the organ and introducing the blunt curette, we find that the cavity of the uterus is quite roomy and large, showing evidence of its dilatation by retained secretion. The curette is passed over the mucous membrane upon all sides, with a view of dragging off any granulations, pressing out of the glands their secretion, breaking small cysts that may be present, and in this way changing an unhealthy into a healthy inflammation. Recently in a case in which the hemorrhage was quite marked, and we supposed there was a possibility of malignant disease, the dilatation and the use of the curette following resulted in the dragging off of a polypus the size of a hazel-nut, and the relief of the patient from the condition that had given rise to her discomfort. We go over the mucous membrane here with the curette, but find nothing more than the evidence of some granulations and the increased bleeding. This patient has been twice advised that an abdominal operation would be necessary, with a view to the removal of the ovaries and tubes. While it is possible that the plan of treatment we are now instituting may not be entirely successful, and that such an operative procedure might yet be necessary, it is still important that the patient should have the opportunity to escape, if possible, from a sacrificial operation.

After the curetting, we wash out the cavity of the uterus with either acid sublimate, or, what I like better, the peroxide of hydrogen. This may be done either by the use of the double catheter or by taking a swab of cotton, dipping it in the solution, and in this way mopping out the cavity of the organ. If there is reason to suppose that considerable infectious material is within the cavity of the uterus, the irrigation will by all means be the most desirable method to pursue. As we were satisfied that in this patient the condition resulted from defective drainage, we will supplement the dilatation, curetting, and irrigation of the uterus by the introduction of the drain through which the discharges of the organ may be able to make their exit. For this purpose I use a drain recommended by Wylie, of New York; it consists, as you see, of a hard-rubber plug with a groove on its side. What I. like still better, is the one recommended by Boldt, in which there are three grooves. With this placed in the cavity of the uterus, we feel perfectly certain that there will be no reason for the locking up within the organ of the discharge. Having carefully wiped out the vagina, we introduce an iodoform-gauze tampon to hold the instrument in place. This gauze is rapidly saturated with the discharges, and does not consequently obstruct their exit from the uterus. It will be permitted to remain there for forty-eight hours, and after its removal the uterine cavity will be irrigated twice daily with a disinfectant solution.

Dilatation of the uterus is not by any means a new method of procedure. It has long been recognized as a necessary plan of treatment in many cases, though the methods of its accomplishment were formerly quite different. The usual method recommended is the introduction of either a sponge, laminaria, or tupelo tent, permitting this by the absorption of the discharges to increase in size and thus dilate the uterus.

Although the sponge may be saturated with carbolic acid, or precautions taken at the time it is introduced to render it antiseptic by the use of salicylic acid, it is still an objectionable method of procedure. The sponge rapidly absorbs the discharge from the uterus and very quickly decomposes, and at the same time the rough sponge irritates the mucous membrane and offers the most favorable soil for the development and absorption of septic material. When this method of dilatation was a frequent one, I have seen numbers of cases in which there had been an extensive inflammation in the uterus, extending to the tubes, and even resulting in the death of the patient. Consequently, I do not only not recommend the use of the sponge tent as a means of

dilatation, but would earnestly condemn it as being far too dangerous for ordinary practice. The laminaria and tupelo tents are less objectionable than the sponge, but they are slower methods of dilatation of the uterus, and consequently, from inability to keep the parts continuously disinfected, are also attended with danger. The use of the sponge tent in increasing the amount of serous discharge from the surface of the uterus, was found very beneficial in reducing the size of the organ. In this way the therapeutic influence of the tent was certainly worthy of consideration, but this result of the treatment can be accomplished by other and less dangerous means.

Dr. Vulliet, before the International Medical Congress in Washington, in 1887, read a paper on a plan of treatment which consisted in tamponing the uterus with antiseptic gauze, preferably iodoform, and repeating this until the uterus was thoroughly dilated; by this plan of procedure he was able not only to dilate the uterus, but also to dilate it so efficiently that the cavity of the entire organ could be inspected. The method consists in packing in the cervical canal iodoform-gauze, which, by capillary action, serves as a vent for the discharges within the uterus. It leads to dilatation of the cervix, to retraction of the uterus, and in this way the organ is rapidly dilated. It is a plan that is slow in action, but the drainage of the uterus with it is perfect, and the increased serous secretions and activity in the uterine walls lead to rapid completion of the process of involution in subinvoluted uteri. If the dilatation is not sufficiently complete by the first introduction of gauze, the cavity of the organ can again be rendered aseptic and a new application of gauze made, in this way enabling the most thorough examination to be made of the cavity of the organ, and in some cases having of itself a marked beneficial effect on the size and condition of the uterus.

A number of years ago a plan of treatment was introduced by Simpson, and extensively followed in this country by Sims, that consisted in bilateral incision of the cervix. In this way the opening was enlarged; patients who had formerly suffered from dysmenorrhea were in the majority of cases relieved, and it not unfrequently had a beneficial effect upon sterility. Sims's plan was to plug up the cavity of the uterus with cotton, sometimes saturated with a styptic with a view of arresting hemorrhage and preventing the reunion of the divided surfaces. This plan of treatment, however, interfered with drainage and in some cases was attended with and followed by the development of septic trouble. The observation of this work led Dr. Wylie to introduce the drainage-tube, an instrument that serves not only to drain the organ, but by its presence stimulates muscular contraction of the uterus with a view to secure its expulsion, and the activity of the circulation thus engendered brings about a reduction of its size.

By the plan of treatment that we have thus pursued in this patient, more is accomplished in the treatment of endometritis than was formerly obtained by months of local treatment. I would recommend this plan in every case of inflammation of the uterine mucous membrane, as by the rest in bed, the increased secretion, and change of surroundings the condition of the patient is rapidly improved. This plan of dilatation and curetting of the uterus is one that is particularly applicable to those cases of septic inflammation following parturition. I have several times been called upon to treat a patient suffering from such trouble and have urged the importance of prompt dilatation and curetting of the organ, thus removing débris that affords a source for putrefactive changes and absorption of the ptomaïnes or products.

In every such case, treatment should be prompt, with a view to limit the extension of the disease to the uterus. If it has extended into the tubes, there is danger of the development of purulent salpingitis, and the formation of large pus-collections. Such cases are ordinarily treated by vaginal, or even intra-uterine irrigation, and with a large accumulation of débris, the germs multiply beneath this, are not reached or affected by the irrigation, or only to a limited degree, and the products are absorbed, giving rise to marked elevation of temperature.

In curetting, the finger is by far the safest and most judicious instrument, as by it the thickness of the uterine walls, their consistency, and the amount of force required to bring about the separation, and the parts affected are more rapidly determined. The curetting should be followed by irrigation with an antiseptic solution. A very good plan is to use, first, the acid sublimate solution, 1 to 2000, then sterilized water, and finally peroxide of hydrogen, following this again by sterilized water. As the surfaces of the uterus are large and flabby, likely to fall against each other and interfere with the subsequent drainage of the accumulations from the organ, the preferable plan of procedure is to introduce a gauze tampon, consisting of a twist of iodoform gauze, to the fundus of the uterus, letting this be sufficiently large to fill up the canal. By its presence this acts as a drain, keeps the surfaces separated, promotes capillary action and secretion, and, as a foreign body, causes contraction of the uterus. The process of reduction in the size of the organ is very rapidly accomplished by this means, and if the temperature has before been high, it will be found to fall nearly, or quite, to normal.

CLINICAL MEMORANDA.

FRACTURED CLAVICLE: A NEW DRESSING.

By EDWARD S. STEVENS, M.D.,
of Cincinnati.

That very common seat of fracture, the clavicle, has furnished the text for many a paper, and the dressings for fractured clavicle are almost without number, yet there is still something to be learned in the way of the proper treatment of this form of injury.

In considering the deformity that is usually present in fractured clavicle, surgeons have generally limited their observations to the immediate seat of the fracture and the muscles acting directly upon the fragments. The more rational method would appear to be that looking to the displacement of the shoulder for the cause of the lapping of the fragments. The weight of the shoulder, and the action of the pectoral muscles and the latissimus dorsi have been given as the forces contributing to drag the shoulder downward, forward, and inward. Another factor in the production of this displacement, which I do not remember to have seen mentioned elsewhere, is the action of the serratus mag-

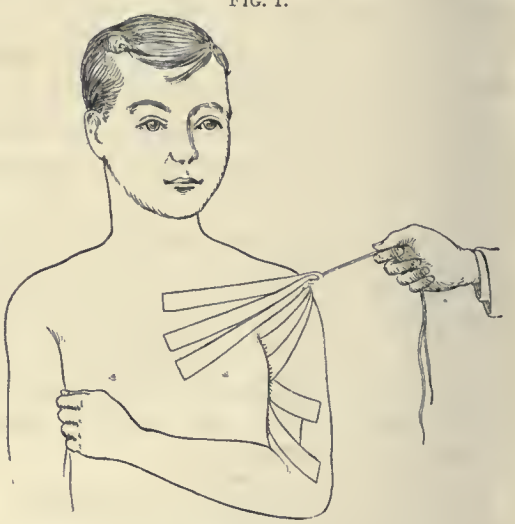
nus. This muscle, acting from the sides of the chest-wall upon the vertebral border of the scapula, will by itself produce the displacement of the shoulder which is to be counteracted in treatment. This view of the injury presents the clavicle as a brace to the shoulder.

The usual plans of treatment have employed a sling for the elbow, a wedge for the axilla, and a retaining bandage, and there have been many modifications of this plan. The method I have to offer is the employment of direct extension and counter-extension.

The late Dr. I. L. Drake, of Lebanon, Ohio, had, for many years, made fractured clavicle a special object of study. The dressing I describe is the result of his earnest work, though I believe he never made use, in a case of fracture, of the dressing to which he had given so much study. The case I report is the only one in which it has been tried.

The extension apparatus consists of six strips of adhesive plaster, each about one yard long and two inches wide, and a cord. The strips of plaster are applied in

FIG. 1.



The extension apparatus.

the following manner: The first is applied directly under the clavicle along its whole length. At the acromio-clavicular articulation the plaster is cut sufficiently from each edge to permit a fold of the adhesive side to be turned upon itself until covered. The strip is then continued spirally around the arm to the elbow. The second and third strips are applied similarly but lower down over the pectoralis major.

The other three are arranged over the back in a similar manner and are wound around the arm in front. The cord is then tied to the strips of plaster where they are folded over the acromio-clavicular articulation.

The apparatus for counter-extension consists of a metallic plate, five or six inches wide and about eight inches long, concave from side to side, so that it will fit the side of the chest; from one end of it a stiff wire is bowed from one side to the other and bent out so that when the plate is fitted to the side the wire, which has been slipped over the arm, will be above and beyond the shoulder. An indentation is made in the wire bow a little back of its central point.

This gives us a fixed point above, behind, and without the line of the clavicle and supports the broken brace to the shoulder. The indentation prevents the cord, which is tied to it, from slipping. To the lower

extremity of the plate there is soldered on each side a wire loop.

The extension-apparatus being applied, the apparatus for counter-extension is arranged and applied as follows: A wide strip of plaster is fastened to the concave side of the plate, the strip being long enough to pass

FIG. 3.

Dressing as applied.

under the elbow and up the outer side of the arm. The plate may then have a light pad of some soft stuff applied to each side. The wire is slipped over the arm to the shoulder; a band is passed over the uninjured shoulder, through the wire loops at the lower end of the plate, and securely fastened; and the plate is bound to the chest by a roller bandage.

Being assured that the fracture is reduced, the cord is firmly tied to the indentation in the wire bow, the arm is placed at the side, and the strip of plaster carried from the plate to the arm. The forearm being permitted to rest in a sling, the dressing is completed.

The foregoing corresponds very closely with the dressing as originally designed by Dr. Drake. In my use of it I did not employ the strip of plaster extending under the elbow between the plate and the arm. Indeed, I believe that if it was thought necessary to keep the arm immovable a roller bandage would answer a better purpose than the strip of plaster. In another case, if I found it best to have a new plate made, I should modify it in this way: Let the bow be made plain, without indentation. At about three-quarters of an inch, or an inch, on each side of the middle let a small ring be fastened to the under side of the bow (Fig. 2, *C*). This will permit of the apparatus being used on either side of the body. As originally designed, it can be used on one side only.

I believe that this dressing could be used with advantage in certain cases of dislocation of the sternal extremity of the clavicle, in which, if one can accomplish reduction, it is ordinarily difficult to maintain it.

The following case demonstrated the practicability of this form of dressing.

Sunday morning, July 26, 1891, Mr. H., aged about sixty-three, in crossing a lot, fell, bruising his arm and the right side. Believing the injury to be simply a bruise, the family made local applications and did not call me in until the next day. I found the right side of the chest and right arm very much discolored, and there was so much swelling over the clavicle and upper ribs that it was difficult at first to tell whether there was a fracture or not. There was the characteristic posture, however, and pressure over the inner portion of the middle third of the clavicle, where there was the most swelling, elicited crepitus. I applied the dressing described, leaving the arm free and the forearm in a sling. Immediately he expressed himself as being more comfortable. Owing to the great swelling, I could not be sure that the fracture was perfectly reduced, and for this reason the case is not entirely satisfactory to me. In the course of a week or ten days the swelling had almost disappeared and showed as little deformity as is usually seen with the old dressings. Indeed, the patient and his wife could see no difference between the two sides, although there was a distinct, though slight, angle at the situation where crepitus has been found. During the nearly three weeks in which he wore this dressing, the only attention needed was on two or three occasions to readjust the bandage that bound the plate to his side, and to tighten the cord at the indentation in the wire bow. Each time the cord was tightened he spoke of feeling more comfortable. The patient removed the dressing himself on the eighteenth day, although I had intended leaving it on for a week longer.

THREE SHOULDER-JOINT AMPUTATIONS.

By GEORGE S. BROWN, M D.,
of Birmingham, Ala.

Case I.—Henry W., colored, fourteen years of age, was a driver of a coal-hopper at the Sloss Coke Ovens. The hopper is a large iron vessel on a small flat car of four wheels, weighing 1500 or 2000 pounds. On January 12, 1890, the boy went to sleep on the track in front of the hopper and the mule pulled it over him, producing the following injuries: The arm was crushed through the surgical neck of the humerus; the acromion process of the scapula was broken off and hanging in the wound; there was fracture of the second and third ribs; an abrasion, half an inch in width, apparently made by the wheel-flange, almost encircled the neck. There was double internal strabismus, which his friends said he did not have before, and hemorrhage from both ears, with profound unconsciousness. No meningeal fluid was seen in the discharge from the ears. The crushed bone and tissues were trimmed from the wound, the axillary artery tied, and the wound dressed. There was no flap to cover it. There was not enough tissue of any kind to cover the glenoid cavity, which occupied the center of the wound. On the third day the boy recovered consciousness, and though from then on he was perfectly rational, he was constantly cross and irritable, and complained of head-pains for about three weeks. On the seventh day an abscess was evacuated two inches anterior to the stump over the site of the fractured ribs. After this the temperature, which had ranged from 101° to 103°, went to normal, and did not rise again. The abscess-cavity was washed out with hydrogen peroxide, and a few minutes afterward, in a fit of coughing, he expectorated what seemed to be the effervescing peroxide; but the washing was repeated daily and he did not again show any evidence of lung-complications. The amputation-wound healed rapidly by granulation, and, what was noticed with interest, independent granulations began exactly in the center of the glenoid cavity, and, when first noticed, were only the size of a pin's head. This point spread to meet the granulations from the borders of the wound and rolled over the edge of the cavity until it was filled to a level. This point of granulation was evidently an accidental epithelial graft which hung there from the washing. I again saw my patient in January, 1892, two years after the accident. The double squint persists unchanged; otherwise he is in good health.

Case II.—J. W. B., white, twenty-one years of age, brakesman, was run over by a freight car January 23, 1890, and the right arm was crushed off two inches from the joint. The axillary artery was tied, the mangled tissues trimmed out, and the drainage-tube used was removed on the second day. The stump completely healed without suppuration in twelve days.

Case III.—H. W., white, twenty-eight years of age, a telegraph operator, was run over by a freight train at 2 A.M., January 16, 1891. The right arm was crushed off three inches from the shoulder-joint. Disarticulation was performed, the artery tied, the flaps approximated, a drainage-tube inserted, and the wound sutured with large-sized catgut. On the sixth day a little rise of temperature had been observed for a day or two; so the dressings were removed; the drainage-tube having been removed on the second day. The line of union was perfect, except at each extremity where the drainage-tube had been; this was suppurating, and every stitch-hole was a suppurating sinus. Water injected into either angle of the wound spurted through the stitch-holes, but did not appear anywhere in the line of incision. The stitch-

holes that were not deep enough to communicate with the track of the drainage-tube were suppurating independently. A few days later a deep abscess over the ligated artery was opened, and two days after this the catgut knot, which had held the axillary artery, came away in the washing. The line of incision of the stump was perfectly healed and the whole trouble was clearly traced to the commercial carbolized catgut, the soaking in alcohol that it had undergone during the time of the operation not having improved it. The healing was complete in three weeks and the result perfect.

In all three of these cases, as the first step in operation, the bruised and twisted axillary arteries were found in the wound, traced up and tied above the clot, which in each case was a full inch from the torn extremity.

MEDICAL PROGRESS.

Two Cases of Thomsen's Disease.—DELPRAT (*Deutsche medicin. Wochenschr.*, 1892, No. 8, p. 158) has recorded two interesting cases of Thomsen's disease, or myotonia congenita, in two brothers in a family in many members of which abnormal muscular contraction seemed to be a common feature. One of the patients was nineteen and the other fourteen years old. In both, attempts at muscular movement were attended with stiffness and spasm, which gradually grew less and disappeared as the movement was accomplished and repeated. Muscular development was excessive. There was some shortening of the flexor muscles of the hands, so that perfect extension was impossible. Muscular mechanical irritability was but little increased; irritation, however, was followed by contraction that persisted for some time. The small muscles of the hand contracted *in toto;* the long muscles presented elevations and depressions at the site of percussion, which gradually disappeared. The knee-jerks were preserved; ankle-clonus was wanting. There was no ataxia. Fibrillary contractions were not observed. The action of the sphincters was not deranged. Sensation was preserved. The reactions of muscle and nerve to faradism and voltaism were at first tardy, but on repeated stimulation or after voluntary movement the responses were ready and active. Tetanic contraction was readily induced. In the first case rhythmical wavy contractions, passing from the kathode to the anode, followed voltaic stimulation of some of the muscles.

Death in an Infant from Laryngeal Obstruction by Vomited Milk-curd.—DEMME (*Bericht des Jenner'schen Kindersp.*, Berne, 1891) has reported the sudden death of a dyspeptic child, ten months old, without recognizable cause, in which at the autopsy the esophagus and entrance to the larynx were found occluded by a coagulum of cows' milk ejected from the stomach by vomiting and causing asphyxia.—*Centralbl. für die gesammte Therap.*, x, 3, p. 171.

Orchitis following Influenza.—BRISCOE (*Lancet*, No. 3569, p. 192) reports the case of a laborer, thirty-two years old, in which, after an attack thought to have been influenza, orchitis developed, without other complication.

THERAPEUTIC NOTES.

Puncture for the Relief of Anasarca.—GERHARDT (*Deutsche medicin. Wochenschr.*, No. 7, 1892, p. 138) proposes to obviate the wound-infection that so often follows the various modes of puncture for the relief of obstinate and intense anasarca by the observance of rigid surgical asepsis and antisepsis. The extremities are cleansed with soap and water and douched with sublimate solution. With a knife, sterilized in carbolic acid solution or in a hot 2 per cent. soda solution, from four to eight punctures are made through the skin. The limb is then wrapped in antiseptic gauze and cotton, and the dressing is carefully renewed as soon as it becomes saturated.

Inunctions of Iodoform in Pulmonary Tuberculosis.—The following are two forms in which FLICK employs iodoform by inunction in the treatment of pulmonary tuberculosis:

℞.—Iodoformi	. . . .	ʒj.
Ol. rosæ	. . . .	gt. j.
Ol. anisæ	. . . .	fʒj.
Ol. morrhuæ	. . . .	fʒij.—M.
℞.—Iodoformi	. . . .	ʒj.
Ol. rosæ	. . . .	gt. j.
Ol. anisæ	. . . .	fʒj.
Ol. olivæ	. . . .	fʒiij.—M.

Asafetida for Habitual Abortion.—In support of the utility of asafetida in the prevention of habitually repeated abortion not dependent upon a recognizable cause, such as syphilis, tuberculosis, disease of the uterus or its appendages, TURAZZI (*Centralbl. für Gynäkol.*, 1892, No. 9, p. 164) has collected forty-one cases from various sources, in thirty-seven of which the use of the remedy was followed by normal labor. Three grains of the gum-resin are given daily from the beginning of pregnancy, the quantity being gradually increased to fifteen grains, with a subsequent gradual diminution in the dose.

Sodium Ethylate in Dermatologic Practice.—Sodium ethylate may be obtained by boiling sodium with alcohol at 122°. Inunctions of the agent (2 parts to 100 of olive oil) have been found useful in psoriasis. Applications of a 10 per cent. aqueous solution in cases of lupus, following curetting, have been followed by permanent improvement.—*La Méd. Mod.*, 1892, No. 9.

For Pruritus Ani.—An ointment containing—

Creasote or carbolic acid .	1 dram.
Lard	2 ounces.
Camphor	1 dram.

Applied topically, is a safe and often effectual remedy for the relief of pruritus ani. WHITLA.

Deodorized Chloroform.—The ethereal oil of coriander-seed is recommended as a deodorant for iodoform. Two drops of oil are thoroughly mixed with each fifteen grains of iodoform.—*Deutsche med. Wochenschr.*, 1892, No. 7.

The Medical News.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to The Medical News will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

SATURDAY, APRIL 9, 1892.

AKROMEGALIA AND ALLIED CONDITIONS.

In bringing together the essays of Marie and Souza-Leite upon akromegalia, together with the bibliography of the subject, and an appendix of cases by other authors, the New Sydenham Society has conferred an important benefit upon English medical literature.

It must be conceded by all that physiologists are far from understanding the complex and varied relations existing between the nervous system and nutrition; while the influence that disease of one organ may exert upon the nutrition of distant and apparently unrelated organs, from failure of proper metabolism, with deprivation of necessary anabolins, or from perversion of metabolism giving rise to the production of poisonous katabolins, is almost an unsurveyed field.

By the careful study of unusual cases, by recording the facts, even without attempts at explanation, all clinicians have it in their power to advance our knowledge of this subject. All cannot be Newtons, to discover by a sudden flash of genius, illuminating previous careful and long-continued study, the great generalization that shall explain the multitude of data; but all can help to accumulate the jots and tittles that a future Newton may combine into a word of light.

Marie is entitled to lasting gratitude for the keen observation and patient industry by which he has erected into a separate group of diseases the trophic lesions of the extremities. There can be little doubt that these cases have been seen from time to time by others, less keen-sighted than Marie and the observers whose cases he has quoted, and have been diagnosticated, perhaps, as chronic rheumatism, or rheumatoid arthritis; or, perhaps, not diagnosticated at all.

It is a common mistake of inexperienced men to see a new disease in every case that differs from the type of a special disease as laid down in the books; but it is no less a mistake on the part of experienced men to force into the Procrustean bed of established nosologic classes every case that comes under their observation.

Charcot, Paget, Marie, Morvan, and others, who have studied the trophic lesions of the extremities, have given us a number of new classes, and doubtless we shall make the same error of forcing too many cases into these classes, as we had done with the cases properly belonging to them, before the industry of the observers cited had given us the new names.

As now established, it seems justifiable to apply the name of *akromegalia*, or enlargement of the extremities, to cases presenting thickening and elongation of the bony structures, especially of those of the hands, feet, and face, associated with overgrowth of the related soft parts, with kyphosis, with a number of more or less constant disturbances of sensation, general and special, with polyuria (sometimes albuminuria or glycosuria), and almost constantly with alteration of the thyroid gland. There is a peculiar shape of the face, which serves to discriminate this disease from the disease described by Sir James Paget under the name of osteitis deformans, and from that described by Virchow under the name of leontiasis ossea, as well as from myxedema, to which it bears some superficial resemblance.

In myxedema the face is round—"moon-shaped"; in akromegalia the facial outline is an elongated, irregular oval. In osteitis deformans, the increase in the size of the head is produced by overgrowth of the bones of the cranium rather than of those of the face, giving an outline somewhat resembling that of a triangle, with the base above, in contradistinction from the lengthened ellipse, almost equal in transverse diameters above and below, of

akromegalia. In PAGET'S disease, moreover, it is the long bones that are chiefly affected, the hypertrophy rarely attacking the hands or feet, or, if so, only to a slight extent. There is likewise a tendency to deformity of the bones, manifested by an outward and forward curving of the tibias and femurs, more rarely of the humeri and the bones of the forearm. This is not seen in akromegalia.

In a certain number of SIR JAMES PAGET'S cases the patients became shorter from this curving of the bones of the leg. In akromegalia, on the contrary, there is more often an increase in the height.

The condition to which the name of "pulmonary hypertrophic osteo-arthropathy" has been given is likewise to be differentiated from akromegalia. It is a condition of deformity and distortion of the fingers, toes, and spinal column, in association with pulmonary or pleural disease. The principal deformity of the digits is a thickening and elongation of the terminal phalanx, with that peculiar parrot-beak-like curvature of the nail to which the term "Hippocratic finger" has long been applied. The nails are longitudinally striated, and exhibit a tendency to split longitudinally. Practically, the condition seems to be an exaggeration of the clubbing of the fingers and disturbance of the nutrition of the nail, long recognized as a frequent accompaniment of empyema and of pulmonary tuberculosis. In akromegalia the deformity affects all of the phalanges, the hand becoming spade-like, and the soft tissues with the bones enlarging laterally, rather than longitudinally. The nail is short and broad, and does not reach to the end of the finger. The kyphosis in akromegalia is rather cervico-dorsal; in pulmonary osteo-arthropathy it is rather dorso-lumbar.

In pulmonary osteo-arthropathy, while there is sometimes a slight projection of the lower jaw, the upper lip is not thickened, the prognathism is less marked than in akromegalia, and the countenance, as a whole, appears to be smaller rather than larger than usual; the nose is sharpened rather than enlarged and flattened, and the facial outline more nearly resembles that of PAGET'S disease than that of akromegalia. In pulmonary osteo-arthropathy, moreover, there is a slight degree of epiphyseal enlargement of the bones of the forearm, and often enlargement of the bones of the leg, both of which conditions are unusual in akromegalia.

The condition called akromikria (STEMBO: *St. Petersburger med. Wochenschrift*, xvi, Nos. 45 and 46, 1891) presents many points of contrast with those just described. There is a diminution in the size of the extremities, of the nose and of the chin. The case described by STEMBO presented features somewhat resembling the condition termed by the French sclerodactylia. The morbid processes began in the terminal phalanges of the fingers, near the root of the nail, and were, in brief, cyanotic discoloration, bullæ, and ulceration, resulting in cicatrization, with loss of finger-substance and of the nails. Microscopic examination of the remains of the nails disclosed the presence of the achorion Schönleinii. The condition differs from MORVAN'S disease in everything but the paronychia and its results.

Similar, but not identical, conditions have been observed in cases of tuberculosis. In this connection reference may be made to recent observations upon the connection of rheumatoid arthritis with suppurative foci in the body, to the series of cases of distortion and atrophy of the fingers reported as of "affinity to RAYNAUD'S disease," by WARDROP GRIFFITH (*Medical Chronicle*, November, 1891), to the arthropathies of spinal disease, and to the muscular atrophy associated with joint-disease. The conditions must have a more or less intimate relation, and that relation is to be found either in the trophic nervous system, in the metabolic cycle, or in both.

To go a step further, cretinism, myxedema, exophthalmic goiter, and rheumatism are not entirely unrelated with one another and with akromegalia and the conditions resembling it. The whole subject offers an attractive field for clinical and pathologic research, and especially for research in that line which is destined to be productive of the most brilliant results in the pathology of the future, namely, pathologic chemistry. B. W. RICHARDSON has long taught that in "perverted zymosis" will be found the explanation of the "synthesis of disease." He has pointed the way, but it has not yet been more than opened to the explorer. Bacteriology has absorbed too much of the energies of medical observers, but perhaps the stimulus that it has given to the institution and organization of laboratories, and the fact that it has now reached a point where chemistry must be invoked to explain the pathogenetic action of bacteria, and the continuing results thereof, will prove of great advantage in furthering the important line of research that still awaits its KOCH.

HYDROGEN PEROXIDE AND THE "CHICAGO TRIBUNE."

Physicians have learned to expect from the secular press, wise and weighty comments on medical matters; but rarely do they find in the columns of a newspaper, comments *so* wise or *so* weighty as those quoted from the *Chicago Tribune* by the *Evening Telegraph* of Philadelphia, on that day long sacred to such wisdom, the First of April.

We allude to the affair as an illustration of the existing widespread and deep-seated cantankerous grudge against scientific medicine on the part of a large portion of the public, the combination of ignorance, impudence, and suspicion always popping up in the newspapers, and even in the best magazines and reviews, itself one of the products of the power of modern quackery in literary and social life.

The learned editor of the great Chicagoan daily does not pretend to have made a new discovery when he states that "the doctors are still groping blindly." The quacks whose advertisements so largely support many newspapers, proclaimed this long ago, in much more picturesque phaseology. It is gratifying to learn that "a few of their (the doctors') number are becoming alive to the truth of the matter;" and although this gratification is for the moment dampened by the information that "the schools still fight shy of it, and their older graduates are averse to investigation in a direction where loss of caste looms up in the distance as a reward for any who may commit themselves to a novelty in theory or practice," joy returns with the confident prediction that "the professional *vis inertia*, cannot, however, avail much longer. Opposition must give way before the pressure of public opinion in favor of rational treatment."

Now comes, however, the announcement of a great discovery of which the sole honor does belong to the learned editor of the Chicagoan newspaper; for surely no pathologist, no botanist, no bacteriologist known to fame has yet taught what this supreme scientific authority of the boundless prairies asserts "there is now no room to doubt"—namely, that the "bacterial causes of disease are mostly composed of albumin eliminated from the tissues of the larger organisms on which they feed."

In the light of this discovery, of course, "The next step is an easy one. If some material can be found that will coagulate these albuminous forms, thus killing them off without destruction of the tissues that have supported them, the problem will have been solved for more than half the diseases that flesh is heir to." Just so!

An ordinary editor would have been content with one such epoch-making discovery; even an extraordinary editor might have considered one revelation so stupendous as this, material sufficient for one editorial; but the genius who presides over the destinies of the great educational sheet of the Windy City, is not an ordinary editor, or even an ordinary extraordinary editor. In the very next sentence he piles Pelion on Ossa, and tells us:

"Such a remedy has been found in the so-called peroxide of hydrogen, or oxygenated water. It can be, and is, produced about as cheaply as soda water, and is a veritable microbe killer, both internally and externally. In the latter respect it is already being used in some of the hospitals and by a few medical men in their private practice. They find it invaluable as a cleanser of wounds, ulcerations, etc., not only destroying the bacterial forms that produce inflammation, but seeming to exert a really renovating action on the tissues, and especially in gradually, though rapidly, stopping the formation of pus. This success may be interpreted as indicating at least a possibility that the oxygenated water can be used with splendid effect in cases of kidney trouble, liver complaint, dyspepsia, diarrhea, rheumatism, etc."

Not to be too ungrateful to the source of his information, the editor graciously remarks that:

"Of course, the best mode of using the remedy in these and other diseases must be indicated by the more intelligent and progressive members of the medical profession. If too strong, it would act injuriously on the tissues of the human frame as well as on the bacteria that infest it; but if it can be thus controlled there is no good reason why the remedy should not be hailed as the long-sought specific which will rid the human race of its deadly burrowing pests, and give man a chance to live out the natural term—which is indicated, by comparisons of growth with longevity for other animals, to be not far from one hundred and twenty years."

A political organ may be successfully conducted by one who believes in spontaneous generation, and is unfamiliar with the researches of Tyndall, Pasteur, Cohn, Koch, Vaughn, Prudden, and their co-laborers—none of whom has yet "lost caste" by his contributions to science. Excellent leaders on the tariff may be written by one who thinks that

hydrogen peroxide was invented by some Chicagoan quack the day before yesterday, and is unaware that this most useful agent was introduced into medical practice in 1858, its beneficial powers fully recognized and its practical limitations accurately pointed out, by BENJAMIN WARD RICHARDSON, "the HUMBOLDT of Medicine," than whom none is more highly or more deservedly honored by "the schools" and by educated physicians the world over. The British lion's tail may be vigorously twisted, and salt sprinkled most gracefully on that of the German eagle, by one whose knowledge of chemistry recognizes no difference between H_2O_2 and "oxygenated water"; whose attainments in physiology warrant the opinion that so unstable a compound undergoes no change in the stomach or the blood; and whose extensive acquirements in pathology enable him to identify the conditions present on a suppurating mucous surface with the profound structural alterations of varied visceral lesions. But when one thus learned in biology and experienced in therapeutics writes a supposably serious article on the causes, prevention, and treatment of disease, it is extremely likely that the product of his lucubrations will be just so wise and just so weighty as the editorial of the *Chicago Tribune*, appropriately quoted by the *Evening Telegraph* on April 1st.

MEDICAL NIHILISM IN OHIO.

A MEDICAL practice bill, described as "a moderate one," that had been formulated under the combined advice of the physicians, the homeopaths, and the eclectics, of Ohio, was lately defeated by the Ohio Legislature—the whole matter being treated as a "screaming farce" by these worthy examples of American nineteenth century politics. In Europe, and, as we have seen, even in Chicago, it has been shown that a half-dozen half-insane cranks can endanger the whole structure of civilized society and bring social life to the point of barbarism. In Ohio, then, we have an example of the same fact in a medical way. Following the Cincinnati *Lancet-Clinic*, let us name these Nihilist crank-legislators of Ohio: PRICE, of Hocking County; DOTY, of Cleveland; JAMES, of Wood County; ELY, of Fulton County; BAIRD, of Ashland. Of course, the newspapers were generally on the side of the "physio-medicals," the patent-medicine men, the drug-stores, and a horde of nondescript quacks, who combined to laugh down the bill through *their* representatives here named. Let us specialize as guilty of this infamy, besides the hounds' chorus of the county newspapers, the Cincinnati *Commercial Gazette*, the Columbus *State Journal*, and the Toledo *Blade*. These should be well remembered. On the other hand, the Cincinnati *Enquirer*, the Cleveland *Leader*, and the Cincinnati *Times-Star* are mentioned as in favor of the bill.

What a revelation of the depths of ignominy and ignorance this fact discloses! The only consolation that can be gotten out of it is that lower depth can hardly be reached, and we may hope that the inevitable progress upward may at last be begun.

And this consolation also: the folly of compromise and the shame of it! After the disgrace of combining with the homeopathic and eclectic quacks in the desperate game, and then to be beaten! The only compromise with certainty of immediate success is that single one still left—to clasp hands with *all* the patent-medicine syndicates and the humbugs and deviltries that sail under our benign-malign laws, and as a body of physicians without a spark of honor, suicide in the open legislative market. Better to have been defeated with honor than thus besmirched with the shame of an ignoble and useless compromise.

CORRESPONDENCE.

THE VALUE OF TUBERCULIN IN THE DIAGNOSIS OF TUBERCULOSIS IN CATTLE.

To the Editor of THE MEDICAL NEWS,

SIR: The last number of THE MEDICAL NEWS contained a notice of the slaughter of a large number of Jersey cows suffering from tuberculosis, belonging to Mr. J. E. Gillingham, of Villa Nova. It was stated that tuberculin had been of assistance in making the diagnosis.

In order to appreciate the value of an agent used for this purpose, it is necessary to have an idea of the difficulties that stand in the way of making the diagnosis of tuberculosis in cattle in the ordinary way; that is, by means of the physical examination. The veterinarian has numerous difficulties to contend with in making physical examinations of his patients that do not trouble the ordinary medical practitioner. Still, except in the case of cattle, these difficulties are not insurmountable. In the cow, bred for milking, and the ox, for beef, the digestive function is all-important, and nature and breeding have developed the digestive organs at the expense of the thoracic cavity. The voluminous rumen is sometimes so distended with solid food that it presses forward against the liver and diaphragm, forcing them into the thoracic cavity, and giving rise to a dull percussion sound over the area where we expect to hear the clear sound yielded by percussion over a thick layer of healthy lung tissue.

This encroachment on the thoracic space is so irregular and sometimes so great that percussion of the posterior portions of the cow's lungs gives results of but little value. Auscultation also is interfered with by the very soft and indistinct breathing, and by the sounds arising in the thick layers of connective tissue separating the lobules of the lungs.

Again, tuberculosis in cattle is by no means confined to the lungs, and frequently exists in other parts of the body, as the bronchial glands, liver, intestinal walls, and mesenteric glands, leaving the lungs perfectly healthy.

In these cases, and they are not at all rare, it is next to impossible, except in the most advanced stages, to diagnosticate the disease by the physical signs. These circumstances have rendered laws dealing with tuberculosis and with other bovine scourges inoperative, or their passage inadvisable. It has been impossible for the veterinarian to detect the disease in its early stages, before it became dangerous to other cattle and to the consumers of the milk and beef.

I met this same difficulty when called upon to inspect Mr. Gillingham's herd of seventy-nine cattle. It was possible, relying upon the physical symptoms, to detect five cases of tuberculosis among all of the animals. It stood to reason that more were affected, for all had been exposed, and it is well known that the disease is contagious among cattle. But which of the animals were diseased? All, even those in which the disease had been detected, seemed, to the superficial observer, to be in good health. They were in good flesh; their appetites were regular and good; they were giving milk normal in color, taste, and quantity.

In this extremity it was decided to use tuberculin. This substance had already been used many times in European countries, and the reports concerning its use as a diagnostic agent were almost uniformly favorable.

The tuberculin used had been sent to Philadelphia about a year before, and it was perfectly clear.

The cows were given injections of doses ranging from 0.2 to 0.4 c.c., diluted with nine parts of a 1 per cent. solution of carbolic acid. The seat of injection was the right scapular region, and the skin was always carefully disinfected with creolin before the operation. The temperatures were taken at the time of injection, again after five hours had passed, again three hours later, and again for the last time after another period of three hours. To avoid possible error the observations were made at night, as the cattle were then quiet, and there was nothing to cause an accidental rise of temperature. It was observed after the injections that in some of the animals the temperature remained stationary, in some there was a slight rise, in some a decided rise, and in some a very great elevation of the temperature. Six of the cows that showed decided febrile reactions were killed publicly at Mr. Gillingham's farm March 16th. All of them were clearly tuberculous, as was demonstrated by the macroscopic and microscopic examinations. Drs. John Guitéras, E. O. Shakespeare, and A. C. Abbott kindly coöperated in the post-mortem examinations, and in each case were fully satisfied as to the tuberculous nature of the lesions.

The twenty-one remaining suspected animals were sent to the Veterinary Hospital of the University of Pennsylvania, and at this writing thirteen animals that reacted to tuberculin have been killed. The autopsies have showed tuberculosis in each case. As the full reports will be published in The Medical News when the investigation is completed, it is unnecessary to go into details of the particular cases in this communication, but the following will indicate the action of the tuberculin in two of the cows:

Cow No. 13. Injected with 0.25 c.c. tuberculin on March 8th, at 6.15 P.M.

Time.	Temp.	Time.	Temp.	Time.	Temp.	Time.	Temp.
6.15	101⅘°	12.30	101⅘°	3.15	101⅘°	6.15	102⅕°

Killed March 30th. The bronchial glands were slightly enlarged, and contained small, cheesy nodes. One cheesy tubercle the size of a pea was found in the left lung. Two small tubercles were discovered in the liver.

Cow No. 35. Injected with 0.25 c.c. tuberculin on March 8th, at 6.50 P.M.

Time.	Temp.	Time.	Temp.	Time.	Temp.	Time.	Temp.
6 50	102°	12.50	101⅘°	3.40	103°	6.45	106⅘°

Killed March 29th. A few cheesy nodules were found at the root of the right lung. The liver contained many small, cheesy tubercles. The uterine mucous membrane was thickly studded with tubercles the size of shot—some fresh, some cheesy. Many nodules were found on the peritoneum covering the spleen. The sublumbar lymphatics were tubercular.

So far as my experience goes, tuberculin seems to be a safe agent for the diagnosis of tuberculosis in cattle.

Very respectfully yours,

Leonard Pearson, B.S., V.M.D.

Veterinary Department,
University of Pennsylvania.

AS TO LACTOPEPTINE.

To the Editor of The Medical News,

Sir: Not long since a travelling salesman called on me in the interest of his preparations. After showing me a number of his leading articles, he brought out his samples of lactopeptine, saying that it was hardly necessary to show this, as all physicians used it. I told him that I had never prescribed a grain of it, and, moreover, I never intended to do so. A very sarcastic and much surprised smile passed over his face, while he said that I was the first physician he had found that did not use it. He told me of one physician in North Carolina who employed it so extensively in his practice that his medical brethren had dubbed him "Lactopeptine Smith."

I have had experience in my student days with the prescription departments of several drug-stores, North and South, and have known something of the practice of several physicians, both of high and low standing. I found his remarks to be in a great degree true—some allowance, however, being made for the exaggeration of drummers. I am not surprised at medical men who are ignorant of all physiologic laws, and have no knowledge of scientific medicine, using lactopeptine. I am, however, very much astonished at a great many of the leading physicians of this country, together with a vast number of well-informed and intelligent medical men, for using and recommending to be used a compound nostrum that is contrary to physiology, thoroughly unscientific, and, as Austin Flint has expressed it, "a

therapeutic absurdity." Notwithstanding all this, one will find testimonials from some of the most prominent men that we have. A no less light than J. Lewis Smith, in his work on *Diseases of Children*, sixth edition, recommends a number of prescriptions containing lactopeptine. These men claim to be reasoners, having the facts before them, and to only act in anything after having found out, as nearly as possible, the reasons why. I can only explain it by thinking that they had been so engrossed with what they consider the "weightier matters of the law" that they have overlooked the simpler and plainer laws of digestion.

The only good thing that I can say of lactopeptine is that it is pleasant to the taste, and, provided it is free from all putrefactive ptomaïnes, that it is about as harmless a drug as can be used. Whenever a placebo is required the elixir will do admirably well.

The Pharmacal Association says that lactopeptine contains pepsin, pancreatin, ptyalin, hydrochloric and lactic acids. These agents are said to be combined in the same proportion as is found in the digestive apparatus. It further adds that they are all the agents necessary for perfect digestion, so that this compound is a remedy for indigestion in any form. What a priceless boon this would be to the sufferers from this almost universal malady if these absurd and preposterous statements were true. Lactopeptine, truly, is a gunshot prescription, which makes it useless for us to bother with accurately diagnosticating any particular form of indigestion. It promises to cure, regardless of the special trouble. Most of us are ready to pay considerable homage to anything promising to save us work, while, at the same time, giving us the desired results.

On looking into the formula of lactopeptine, it must appear to every scientific man at the most casual glance that it contains one agent not probably necessary for digestion, others that are chemically incompatible, and still others that have no relation to the subject or influence upon the malady.

I will make these statements plainer by going somewhat into details:

1. Lactic acid is probably a by-product of digestion, and not essential to it. The most approved analysis of the gastric juice does not contain any mention of lactic acid (analysis by Bidder and Schmidt). Landois and Sterling, in the second edition of their *Physiology*, say that "lactic acid is usually met with in the gastric juice, but it arises from the fermentation of carbohydrates in the food." In the third American edition of Foster's *Physiology*, in speaking of the composition of gastric juice, it is said: "Lactic and butyric and other acids, when present, are secondary products arising by their respective fermentation from articles of food or from the decomposition of their alkaline or other salts." Arising, as it does, from the fermentation mostly of the carbohydrates, one can always safely depend on lactic acid being present, so that if it fills any office its place will not be vacant.

2. Pepsin acts only in an acid medium on proteids. Ptyalin and pancreatin act only in an alkaline medium on proteids, carbohydrates, and hydrocarbons. Thus it is seen that we have two sets of agents combined of which the chemical and physiologic properties and functions are entirely opposed.

3. If the muriatic acid be put in lactopeptine in sufficient quantity to be of any value in indigestion, it will probably destroy the properties of pancreatin and ptyalin by the prolonged contact, especially during the heat of summer. This may not, however, take place.

4. If the pancreatin and ptyalin escape the muriatic acid in the compound, certain death and absolute destruction await them in the stomach, for there the hydrochloric acid is in sufficient amount, and will surely destroy all of the properties previously possessed by these agents. It may be argued that they are not entirely destroyed, but that their functions are simply held in abeyance while in the presence of gastric digestion, and that they resume their activity as soon as they pass into the duodenum, where they find an alkaline medium. To all who would thus argue, allow me to cite some authority which will tend to substantiate the correctness of the aforesaid statement. Landois and Sterling (quoting Chittenden, Griswold, and Langley) say: "Ptyalin is destroyed by hydrochloric acid or digested by pepsin." Foster, in his *Physiology*, in speaking of the action of saliva, says: "Indeed, the presence of even a small quantity of free acid, at all events of hydrochloric, not only suspends the action, but speedily leads to permanent abolition of the activity of the juice."

It is presumed that pancreatin means an extract of the whole juice, and is supposed to contain the main agents, namely, trypsin, amylopsin, and steapsin.

Foster, in speaking of trypsin, says that "it is destroyed by heating with dilute hydrochloric acid to 40° C." (slightly above the body temperature). The same authority says the "amylolytic ferment is identical with ptyalin," therefore it would meet the same fate when brought in contact with the hydrochloric acid.

Landois and Sterling say: "As trypsin is destroyed by gastric digestion, obviously it is useless to give extract pancreas to a patient along with his food." They say, speaking of amylopsin: "All conditions which destroy the diastatic action of the saliva similarly affect its action." Bartholow, in his *Materia Medica*, says: "Pancreatin differs from pepsin in that its action is promoted by an alkaline medium and destroyed by strong acidity." Yeo, in Hare's *System of Therapeutics*, quotes Chittenden, thus: "Hence it is obvious that pancreatic extracts or ferments given by the mouth can be of no value whatever, since the proteolytic action will at least be undoubtedly destroyed in the stomach before it reaches its normal sphere of action." W. W. Johnson, in THE MEDICAL NEWS, March 12, 1892, says: "The objections to giving pancreatin after a meal are so obvious that few have much faith in its efficacy; even a short stay in the stomach on its way to the duodenum will expose it to the action of the gastric juice, and its activity as a ferment will be destroyed."

It may be said that hydrochloric acid cannot have a destroying influence on pancreatin for the reason that dilute acid is used officinally in its extraction. This is true, but it is done at a moderately cool temperature. Heat it up to 98.6° F., and then see how much active pancreatin there is left. If there be any, add a little pepsin and some proteid substance, thus producing artificial digestion; now test for pancreatin, and it will be found that it will take a creative hand to bring back that which was lost.

5. Hydrochloric acid is in too small amount to be of any material value as a pepsin-aider.

6. The pepsin also is in too limited quantities to be of much worth except on the principles of homeopathy, and in that case the stomach would be convulsed with fear of being digested itself.

The pepsin in the compound may possibly be of some value. The same can hardly be said of the muriatic acid on account of the small quantity. These two agents are the only ones that possess any show of merit; the others, as has been shown, are absolutely worth nothing thus combined and given. The foregoing are facts, and I challenge scientific contradiction. They are not by any means new, yet in the light of all these our physicians in these United States have thus caused to be sold a proprietary preparation the very composition of which proves physiologic ignorance and the prescription of which is quackery.

Some physicians will say that lactopeptine may be wrong from a chemical standpoint, but that they are justified in its use from practical experience. Allow me on this point to relate a little incident occurring during my clerkship in a drug-store in Baltimore. One of the most prominent physicians of that city used very frequently to come into our store and get a dose of elixir of lactopeptine to relieve him of indigestion. He prescribed it extensively in his practice, and got from it, he told me, excellent results. On one occasion he came in and took a tablespoonful to relieve him of an attack of indigestion caused by an excess of oysters. Two hours later he came back on some other business. I asked him if he was relieved. He said, "Why, certainly; lactopeptine acts on me like magic." The elixir that we gave him, and that he dispensed in his prescriptions, was all right save in one particular, that it contained absolutely no lactopeptine. For economic reasons the proprietor always left this out. If the elixir relieved him or any of his patients by virtue of the contained drug, it must have been by some unknown dynamo-homeopathic force. Thus, in a limited way, one may see the value of competent human testimony as to practical results.

I would like the editor of The Medical News to expose in his characteristically fearless manner not only this worthless nostrum, but several others in the use of which the medical profession is gulled.

George Walker.

Yorkville, S. C.

URIC ACID AND RHEUMATISM.

To the Editor of The Medical News,

Sir: The Medical News of March 19, 1892, contains a criticism by Dr. James Wood on the article, "Is Uric Acid a Prime or Sole Factor in the Causation of Rheumatism?" in The Medical News of February 13, 1892. Dr. Wood denies that uric acid is produced in the system by a stimulating, nitrogenous diet and the use of alcoholic beverages. The statement, however, is substantiated by good authority. I might add that certain nervous influences, sedentary habits, too free ingestion of carbohydrates and hydrocarbous, CHO compounds, are also etiologic factors in its production. I made no assertion, as claimed, that a nitrogenous diet is stimulating.

Dr. Wood finally arrives at the same affirmative conclusion in his theoretic reasoning as myself, viz., that the suboxidation of proteid or nitrogenous foods by too free ingestion of the CHO compounds, and alcohol, results in the production of uric acid, which circulates through the tissues of the body.

Reasoning from cause to effect, the greater the amount of nitrogenous foods, CHO compounds, and alcohol ingested, the larger the quantity of uric acid that must be produced. The excess of uric acid in the urine above normal, as shown by examination, is the expression of the amount of these foods ingested above that oxidized and assimilated in the system.

It is also denied that "uric acid by its irritating influence upon the lower-grade tissues of the body gives rise to the rheumatic attack;" it is stated, however, that lactic acid is the factor producing it. The statement and reasoning are purely hypothetic, and so acknowledged by standard authorities. It is a well-known fact that uric acid is a purely excretory substance, eliminated from the system as a dangerous factor to its well-being—when produced under normal conditions; if present in excess of the power of the system to eliminate, then it circulates through the tissues as a powerful, irritant poison. Is it not logical to infer that many inflammatory processes, viz., rheumatism, neuritis, endocarditis, endarteritis, tubal nephritis, etc., result from this irritation?

These deductions are substantiated by clinical observations *that cannot be ignored.* These inflammatory processes are often associated, the urine at the same time showing an excess of uric acid, which is but the reflection of what is taking place in the body, viz., the excessive production of uric acid.

The treatment of rheumatism helps to confirm these deductions: limiting the quantity of nitrogenous foods, CHO compounds, and alcoholic beverages, so that the amount is not greater than the system can properly care for, assisting assimilation by change of habits (sufficient exercise and outdoor air), attention to the digestion and regulation of the functions of the liver by appropriate medication, and the administration of remedies to clear out the excess of uric acid from the system. If such a course be followed, the result is seen in the checking or "curing" of the rheumatic attack.

The final objection of Dr. Wood is to the education of our rheumatic patients in an intelligent watchfulness over the citadel of their souls: in the selection of proper food, abstinence from too free a nitrogenous diet and the imbibition of alcoholic beverages. I may also add that the CHO compounds should be used sparingly.

I regard the condition of the urine, as regards quantity, appearance, hyperacidity, etc., an almost infallible guide in rheumatic affections. The use of the mineral waters—Vichy, seltzer, Carlsbad, and the Manitou soda of my own State—is to be commended. The habitual use of the mineral waters by rheumatics is the best treatment (medicinal) to maintain a healthy equilibrium in the system.

Finally, Dr. Wood asserts that "If humanity should receive the education, all diseases of which the great etiologic factor is decreased nutrition and vitality would be greatly increased." Such an hypothesis seems to me absurd and not sustained by chemico-physiologic or pathologic facts. On the contrary, such an education,

if followed out, would tend to restore an already weakened nutrition and vitality, caused by the imperfect oxidation and assimilation of food-products, of which uric acid is but the expression, and prevent the dire results predicted by my critic.

Very respectfully,

W. E. SHOTWELL, M.D.

DENVER, COLORADO.

REPORTS OF CONTAGIOUS DISEASES.

To the Editor of THE MEDICAL NEWS,

SIR: There is no question that "an ounce of prevention is better than a pound of cure," and if, in the administration of the Health Department of a great city like Chicago, the spread of contagious diseases can be prevented by enforcement of the health laws of that city, there is compensation enough in the good health of the citizens to justify whatever measures are used to hold these diseases in check. Whether it be the "barbaric placard nailed to the door," or the rigid quarantine which temporarily houses the inmates of a home in which such contagious disease exists, or whether it be isolation in some contagious hospital, the end justifies the means. We have the satisfaction of knowing that the public health, at least, will not suffer. Chicago physicians should feel proud of their Health Warden, and lend him all honorable means and methods at their disposal to purge that city of its plague of contagious diseases. It is opportune, in the interest both of scientific medicine and public health, that statistics be gathered regarding the prevalence of typhoid fever in that great city. If some prominent physicians refuse to return statistics or reports of contagious diseases, because they are not paid for it, it will lead the medical world to believe that they too are a part and parcel of the cartoon presented in the *Inter-Ocean's* contest, representing Chicago as grasping for the "almighty dollar." If love for his profession and the record of its scientific progress, and the welfare of his own city, are not motives enough to prompt any Chicago physician to let the dollar question drop, then we believe that the old Hippocratic oath is entirely too barbaric for Chicago. The question, "What right has the city to ask a physician to do its work for nothing?" is answered by saying that the love of home, of city, of country, and of scientific medicine ought to make a physician regard his services as complimentary and above money value, when the knowledge he possesses is capable of being utilized to their good.

FRANK P. NORBURY, M. D.

JACKSONVILLE, ILLINOIS

A REQUEST FOR EMBRYOLOGIC MATERIAL.

To the Editor of THE MEDICAL NEWS,

SIR: During the last few years the kindness of several physicians has enabled me to procure for study about a dozen human embryos less than six weeks old. As a specialist in embryology, I ask if you can aid me in procuring more material. I would be indebted to any readers of THE MEDICAL NEWS who would send me such specimens.

Care should be taken that the specimen be not injured by handling; nor should it be washed with water. It may be carefully placed in a tumbler, and as soon as possible preserved in a bulk of alcohol (eighty per cent.) at least five times as large as that of the ovum. If the ovum is not larger than a pigeon's egg, it should not be opened before hardening. When a specimen is to be sent by express, it should be placed in a bottle completely filled with alcohol, with a very loose plug of absorbent cotton both above and below it.

Thanking you in advance for any aid that you may be able to give me,

I am, very truly yours,

F. MALL.

CLARK UNIVERSITY, WORCESTER, MASS.

REVIEW.

A SYSTEM OF PRACTICAL THERAPEUTICS. Edited by HOBART AMORY HARE, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia; assisted by WALTER CHRYSTIE, M.D. In three volumes. Volume II.: Fevers; Diseases of the Respiratory System, Circulatory System, and Hematopoietic System; Diseases of the Digestive System. Large octavo, 1148 pages, with 96 illustrations. Philadelphia: Lea Brothers & Co., 1892.

IN an exhaustive treatise like that under review, in which the different sections represent the work of different writers, it is inevitable that there should be some inequality among its various parts. The very arrangement of the book tends to bring out in full force the points of contrast and comparison between the different articles. These differences were less marked in the first volume than they are in this, the second, partly because of the smaller number of subjects there considered and the smaller number of contributors. Even the casual reader cannot escape being struck by the fact that there is a good deal of repetition, not at all harmful, but perhaps obviable. This is particularly so with regard to the acute infectious diseases, in consideration of which, especially in indicating the lines of prophylaxis, a good deal of the same ground is gone over several times. The individual articles are not thereby weakened, but the interest of the consecutive reader is likely to lag. It is obvious that in many instances a mere recitation of the therapeutic procedures to be employed in a given condition could be made in a few lines; but interest is given to the subject by appropriate clinical and pathologic considerations. The work is not solely a Therapeutics in the narrow sense of the word. Its practical bearing must constitute its most valuable feature. A little more care in editing might have prevented several typographic and grammatic errors. We can only refer to the more important articles. Dr. Robert W. Taylor contributes an aggressive article on Syphilis. He speaks from a large experience; and while some may differ with him on certain points, it must be admitted that his opinions carry with them the weight of authority. Dr. J. Lewis Smith in an able manner discusses the treatment of Scarlatina, Measles, Rötheln, and Varicella. The article of Dr. William H. Welch on the treatment of Smallpox is a most valuable one. Dr. Frederick P. Henry presents a most thoughtful consideration of the treatment of Typhoid Fever. The article is one of the best in the volume. One statement is worthy quotation: "A bedsore has no

legitimate place in the clinical history of typhoid fever. It is neither a complication nor an intercurrent affection: it is a blunder." Dr. George Dock explains the mode of activity of quinine in malarial diseases, and describes the different methods of administering the remedy. Dr. J. C. Wilson presents a concise *résumé* of the measures to be employed in the treatment of Cerebro-spinal Fever. In his article on Diphtheria and Croup, Dr. J. Chalmers Cameron accepts the identity of the two affections, and necessarily advises a common treatment for both. Dr. James T. Whittaker contributes interesting papers on Asthma, Acute and Chronic Bronchitis, and Whooping-cough. The subject of Diseases of the Pleura has been most ably and fully handled by Dr. Rudolph Matas. Dr. T. Lauder Brunton presents a most interesting consideration of the Nervous Diseases of the Heart. The article on Acute and Chronic Gastric Catarrh, Gastric Atrophy, Gastric Ulcer, Gastric Cancer, and Gastric Dilatation, by Dr. D. D. Stewart, is most creditable to its author, and shows evidence of much careful thought. Dr. Edward Martin contributes a practical paper on Obstruction of the Intestines. Dr. Roswell Park furnishes the indications for treatment in Peritonitis, Appendicitis, and Perityphlitic Abscess. Dr. Charles B. Kelsey fully considers Diseases of the Rectum and Anus.

NEWS ITEMS.

On the Death of Dr. Agnew.—At a meeting of the Medical Faculty of the University of Pennsylvania, held Thursday, March 24th, the following minute was adopted:

The Faculty of the Medical Department of the University of Pennsylvania desires to place on record its profound grief at the irreparable loss sustained in the death of Dr. D. Hayes Agnew, and to express its thorough appreciation of the nobility of his personal character and the enduring excellence of his professional achievements.

Dr. Agnew was for years a regular attendant at the meetings of this Faculty, and his wise counsel, his unswerving advocacy of every progressive movement, and of all that tended to raise the standard of teaching and of the profession, have left their indelible mark on the history of its proceedings.

As a didactic lecturer he was unsurpassed. Without apparent effort and with a skill born of thorough knowledge and perfect mastery of his theme, each subject was presented to the student so clearly, simply, and directly, that it remained a part of his medical knowledge.

As a clinical lecturer, his enormous experience and his diagnostic and operative skill made him preëminent. That skill, which amounted to genius, was the foundation of his scientific greatness, and often enabled him at a glance to detect conditions which had eluded the search of others. No clinical observation, even in times long past, escaped his memory, and his experience, almost without exception, furnished a parallel to the rarest and most obscure cases. He had, in addition, the faculty of elucidating in a few words the methods by which he reached his conclusions, and this unusual combination of qualities gave him his unquestioned position as the leading teacher and practitioner of surgery in this country. His colleagues can bear witness to his warm friendship, which never failed in time of need; to his genuine love for his work and his eager desire to acquire every new fact that might benefit his patients; to his generous support of the feeble, the halting, and the unfortunate in the profession; to his respect for every honest opinion, even if it differed from his own; to his quick and ready sympathy and his tender treatment of all those who claimed either his personal or his professional help. His gentle courtesy and kindly bearing won the love of all with whom he came in contact. To the members of this Faculty—his students of years gone by, his colleagues of yesterday, and always his loving friends—his death comes as a personal bereavement.

At a meeting of the graduating class of the Medical Department of the University of Pennsylvania the following preamble and resolutions were adopted:

Whereas, It has pleased the Inscrutable to take from us our most beloved Emeritus teacher and counsellor D. Hayes Agnew;

Resolved, That the members of the medical class of 1892, of the University of Pennsylvania, do hereby express their sincere sorrow at the termination of this noble and mature, yet still fruitful life.

Resolved, That the memory of his pure, unselfish character shall be cherished by them as an inspiration in their life-work.

Resolved, That a copy of these resolutions be forwarded to the bereaved widow, and that they be published in the *University Medical Magazine*, in The Medical News, and the daily papers.

The Pan-American Medical Congress.—A legal form of application for Articles of Incorporation of the Pan-American Medical Congress was made in Cincinnati on March 15, 1892. At a meeting of the Incorporators held on the following day, regulations recommended by the Committee on Permanent Organization were adopted. The first Congress will be held at Washington, September 5, 6, 7, and 8, 1893. The following countries will be represented:

Argentine Republic, Bolivia, Brazil, British North America, British West Indies (including B. Honduras), Chili, Honduras (Sp.), Mexico, Nicaragua, Paraguay, Peru, Salvador, Colombia, Costa Rica, Ecuador, Guatemala, Haiti, Hawaiian Islands, Santo Domingo, Spanish West Indies, United States, Uruguay, Venezuela, Danish, Dutch, and French West Indies.

The languages of the Congress will be Spanish, French, Portuguese, and English.

There will be Sections in: (1) General Medicine, (2) General Surgery, (3) Military Medicine and Surgery, (4) Obstetrics, (5) Gynecology and Abdominal Surgery, (6) Therapeutics, (7) Anatomy, (8) Physiology, (9) Diseases of Children, (10) Pathology, (11) Ophthalmology, (12) Laryngology and Rhinology, (13) Otology, (14) Dermatology and Syphilography, (15) General Hygiene and Demography, (16) Marine Hygiene and Quarantine, (17) Orthopedics, (18) Diseases of the Mind and Nervous System, (19) Oral and Dental Surgery, (20) Medical Pedagogics, (21) Medical Jurisprudence.

Contributors are requested to forward abstracts of their

papers, not to exceed six hundred words each, so as to be in the hands of the Secretary-General, Dr. C. A. L. Reed, Cincinnati, Ohio, not later than the tenth of July, 1893. These abstracts will be translated into English, French, Spanish, and Portuguese, and will be published in advance of the meeting for the convenience of the Congress.

The following have been elected Trustees: Dr. W. T. Briggs, Tennessee; Dr. George F. Shrady, New York; Dr. P. O. Hooper, Arkansas; Dr. S. S. Adams, District of Columbia; Dr. H. O. Marcy, Massachusetts; Dr. J. F. Kennedy, Iowa; Dr. H. D. Holton, Vermont; Dr. L. S. McMurtry, Kentucky; Dr. N. S. Davis, Illinois; Dr. Levi Cooper Lane, California; Dr. I. N. Love, Missouri; Dr. Hunter McGuire, Virginia; Dr. J. C. Culbertson, Illinois; Dr. A. Walter Suiter, New York; Dr. C. H. Mastin, Alabama.

Drs. L. S. McMurtry (Ky.), I. N. Love (Mo.), and W. W. Potter (N. Y.) were designated to act as members of the Executive Committee.

A Laryngectomy in Jefferson Medical College Hospital.—At his regular clinic, on April 1st, with the assistance of Professor W. W. Keen and the Surgical Chief, Dr. O. Horwitz, Professor J. Solis-Cohen excised the entire larynx and the first ring of the trachea from a man forty-five years of age, leaving the epiglottis in position. The case was one of extensive sarcoma of the larynx, protruding externally. Prophylactic tracheotomy had been performed for Dr. Cohen by Professor Forbes at one of the clinics of the latter, and subsequently Dr. Cohen, with the assistance of Dr. Forbes, had removed an external growth with a large circumference of integument, and had then split the larynx and shelled out the intra-laryngeal portion of the growth. Recurrence ensuing, laryngectomy was practised as the sole procedure adequate to effective removal.

The operation was quite difficult on account of changes due to the previous operations. It consumed one hour, two ounces of chloroform, carefully administered by Dr. Williams, sufficing to keep the patient anesthetized.

A tampon-canula was introduced, and the trachea was packed with gauze above this. A soft stomach-tube was introduced through the wound, the edges of which were loosely stitched without any dressing in the pharynx, Dr. Cohen having observed that dressings in the pharynx produce a continuous desire to swallow, which is very annoying to the patient. The patient was put to bed with his head lower than the shoulders, so as to secure drainage through the mouth.

As we go to press we learn that the patient has been fed by enemata; that the tampon-canula was removed from the trachea on the third day and replaced by an ordinary double canula, and that the patient was able to swallow a few ounces of milk on the fourth day, so that thus far there has been no use for the stomach-tube. The case is progressing very satisfactorily.

Philadelphia Polyclinic Hospital.—An examination for the position of two internes and two externes in the Hospital of the Philadelphia Polyclinic will be held May 3, 1892. The Committee will meet and examine the candidates on the date named, at 8 P.M., in the Hospital building, Lombard Street, west of Eighteenth.

A number of clinical assistants will be appointed. Application should be made to the Committee: G. E. de Schweinitz, M.D., H. Augustus Wilson, M.D., S. Solis-Cohen, M.D., T. S. K. Morton, M.D., and Harris A. Slocum, M.D.

The Association of Military Surgeons of the National Guard of the United States will hold its second annual meeting at St. Louis, Mo., April 19, 20, and 21, 1892. Papers will be read and discussed by regular Army and Navy and National Guard medical officers.

Teaching the Deaf.—The annual summer meeting of the American Association to Promote the Teaching of Speech to the Deaf will be held from June 22d to July 1st inclusive, at Crosbyside Hotel, Lake George, N. Y. This will in no wise conflict with the proposed conference of principals and superintendents of deaf and dumb institutions in Colorado.

WHAT RELATIONSHIP HAS CHRONIC NEPHRITIS TO PULMONARY TUBERCULOSIS?

BY S. J. RADCLIFFE, M.D.,
OF WASHINGTON, D. C.

WHEN a person has suffered in early life from all of the symptoms of pulmonary tuberculosis, the progress of which was soon arrested or aborted, leaving behind no sufficient physical signs to indicate its former existence, and he afterward lives apparently a comfortable and healthy life for a long period, dying later of chronic nephritis we are naturally inclined to wonder at the circumstance, to look for the cause of the transition from the one to the other, and to think that there must have been some connection between the two diseases, or that the one was the sequence of the other. It is in this sense that I view the relationship of chronic nephritis to pulmonary tuberculosis, and I give the following cases in illustration of my meaning:

A medical student, with no especial family history of pulmonary disease, was during youth sparely built and delicate. He had a cough and frequent slight hemorrhages from the lungs, during his medical pupilage, and every symptom pointed to early incipient pulmonary tuberculosis. After graduation, his condition growing markedly worse, he was compelled to seek outdoor exercise and fresh air by horseback-riding, seeing his patients on horseback, and under treatment he gradually improved in general health, the hemorrhages ceased, all the physical signs abated or disappeared, and toward his fortieth year he became quite stout, weighing about one hundred and sixty-five pounds, and seemed quite robust, giving his friends no further uneasiness on account of any tuberculous tendency. At about his forty-seventh year, symptoms of nephritic trouble began to reveal themselves, with increased flow of urine, albuminuric retinitis, and loss of sight of the left eye and impaired sight in the right, palpitation and irregular action of the heart, and dyspnea; and his urine was loaded with albumin and granular and fatty casts. How long this condition had lasted could not be ascertained. His friends were first apprised of it by his loss of sight, and the ophthalmoscope revealed its true nature. Knowing his condition he refrained from speaking of it, as he well knew the fatal issue. He continued to attend to his practice until about a month before his death, when he took advice and gave up all business. His symptoms grew rapidly worse, the secretion of urine almost ceased, convulsions came on, in one of which he died, at the age of fifty years. At no time was there any evidence of dropsy.

The second case was that of a man, a civil engineer by profession, with a history of tuberculosis in some portions of his family. So far as he knew there had been no cases of kidney-disease in his family. He was not particularly strong during youth and maturity, but finished his time in learning his profession without serious difficulty. At twenty-two years of age he began to cough and expectorate, and occasionally spat blood, amounting sometimes to slight hemorrhage. He lost appetite and flesh and had night-sweats. Auscultation and percussion revealed a limited area of dulness at the left apex, with moist râles. He was advised to spend the winter in the South, to be out in the open air as much as possible, with moderate exercise on horseback, if possible, and to have a certain amount of treatment. On his return, after an absence of three or four months, his condition had greatly improved, and he was able to resume his occupation. In the course of the next five years he gradually gained in health, and at the end of that time had apparently recovered from his lung-trouble. The area affected had seemingly not extended, and the examination showed what was possibly a mere cicatrix of the former diseased portion. In his thirty second year, he had pain in the back, of a gnawing, disagreeable character, with blinding headaches and stiffness of the calves of the legs, and great despondency. On examination he was found to have albumin and granular casts in his urine, but not to any great extent; the diagnosis was chronic nephritis. His trouble increased during the next three years, preventing his continuous attention to business, at the end of which period he died in a state of uremic coma, in his thirty-fifth year. He had occasionally edema of the lids and cheeks and stiffness of the calves, but no distinct dropsy was observed at any time during his illness.

The third case was that of a man of extensive business habits and great energy. He had a decided family history of pulmonary tuberculosis, which he always feared. During his youth and early manhood he was tall and spare and inclined to stoop. At about his twenty-fifth year, while dancing at an evening entertainment, he suddenly felt a free gush of hemorrhage from the lungs. He felt sick and alarmed, went home, and made up his mind that he was about to die, but by advice he began treatment. He walked and rode a great deal, and was much of his time in the open air. The hemorrhages stopped after a few months, and gradually the lung-affection ceased to occasion any uneasiness, and there was left at the end of the next three years only a slight dul-

ness at the right apex and some dry bronchial breathing, somewhat cavernous. He became stout in his thirtieth year and seemingly strong, and was able to attend to his large business interests. He was not aware of any kidney-disturbance until about his fiftieth year, when he became convinced that something was wrong. He began to drink mineral waters recommended to him, and went several times to the Springs, but with varying results. He went on in this uncertain way for nearly two years, losing much time from business, often not able to attend to any. On examination he was found to have chronic nephritis in the form of contracted or cirrhotic kidney, the progress of which had been slow and had continued for probably ten years. During the last few years of his life he had variable health, but it rapidly declined toward the last, and he died in uremic coma, at the age of fifty-nine years, no dropsy having been discovered at any time.

I am not aware that any extended notice has been taken with reference to the relationship of chronic nephritis to tuberculous disease of the lungs. Pulmonary tuberculosis has frequently been observed as a complication of chronic nephritis, and the latter is often seen as an associated condition, and also as a result of certain wasting diseases, such as scrofula, caries, necrosis, syphilis, and general tuberculosis; but as to the causal relation of the two affections, to the etiologic significance of those things that bear equally and alike upon either or both—in the sense that, while each may be an independent affection, both are each subject to the same etiologic factors—this view of the subject seems to have been in a measure overlooked, or perhaps passed by as a subject not promising any especial compensating results. While these complications may exist—chronic nephritis with tuberculosis, and tuberculosis with chronic nephritis—it is also true that tuberculosis of the kidney may occur alone, as the result of general miliary deposit, or independently of disease of the lungs, just as tuberculous disease of the lungs may be confined entirely to those organs without complications in other organs.

It often happens that disease of the kidneys—chronic nephritis—is not discovered in persons dying from tuberculosis of the lungs until a post-mortem examination is made; during life, examination of the urine of patients suffering from tuberculous disease of the lungs will frequently disclose the existence of chronic nephritis, which had not previously been suspected. It is in the sense therefore of total independence of the two affections and total distinction as to locality, and yet governed by the same law of contact and development, and placed in the same etiologic category, that I use the words relationship of chronic nephritis to pulmonary tuberculosis; and based upon this as a predicate, I would say that either chronic nephritis or tuberculous disease of the lungs may occur in a subject predisposed, or by contact; that the exciting cause may alight upon either the lungs or kidneys indiscriminately, whichever at the time may be the most vulnerable, just as one may have from the same exposure a tonsillitis, or an articular rheumatism, or a peritonitis, or dysentery.

I have often thought of the subject in this light, and from frequent clinical experience or observation, I have been strongly impressed with the thought that some such connection exists. Of course, this connection would be difficult of proof or demonstration, but not more so than many other problems in medicine—not harder than the distinction of tuberculosis of the lungs itself or its therapy, or the true pathology of diseases of the kidneys. We know that these affections are accompanied by certain signs and symptoms, are of certain or uncertain course during life, and reveal certain anatomic changes after death; beyond this we know comparatively nothing. Why the bronchioles, air-cells, and parenchyma of the lungs should be attacked by a particular form of inflammation of a destructive character, with a particular kind of suppuration in which bacilli are found, and why the tubules, vessels, glomeruli, Malpighian tufts, and cortical substance of the kidneys should be the subject of another peculiar inflammatory process of an equally destructive nature, the chief characteristics of the discharge from which are albumin and certain tubular, granular, fatty, or waxy casts, cannot be said to be "in a nutshell," or explained in a few words. And it is just as probable, if bacilli are the cause of pulmonary tuberculosis, that chronic nephritis, "consumption of the kidneys," may have the same or similar origin, for it is just as probable that bacilli could have ingress by way of the alimentary tract, through the circulatory channels, and find a lodgment in the kidneys, as that bacilli should find their way to the lungs by way of the respiratory apparatus. Whether the bacilli are the same is another question. Tubercle-bacilli have been discovered, but I am not sure if bacilli have been found in the kidneys or its discharges, or, indeed, whether any attempt has been made to find them, or even if attention has been directed that way.

Grainger Stewart says, in his *Treatise on Bright's Disease of the Kidneys*, under the head of Causal Complications: Tubercle of the lungs (he says he employs tuberculosis in the old sense, as including all the forms of "phthisis," and not in the more accurate sense now generally recognized) existed in about one-half of all the cases of waxy kidney which I have examined in the Infirmary; tubercle of the intestines in about 18 per cent. In a very considerable proportion of these cases it appeared that tuberculosis was the cause of the renal disease. When we analyze, he says, the relationship more closely

we find that tubercle of the lungs was especially associated with the earlier stages; for, of those fatal in the first stage it was present in 66 per cent.; of those in the second, in 60 per cent.; and of those in the third, in 35 per cent. When we compare, he continues, this with what we find in other forms of renal disease, the relationship between tubercle and the waxy degeneration becomes manifest, for, with the inflammatory forms it was present only in 7 per cent.; with the contracting, in 23 per cent.

These post-mortem examinations were made with reference to, and mainly to discover the extent of, the renal lesions following fatal cases of chronic nephritis and only incidentally that of the pulmonary disease. It is more than probable that if such systematic investigations were made in all cases dying from pulmonary tuberculosis, in a majority of them, doubtless, extensive lesions of the kidneys would be found, showing a certain amount of changeability or compensating action, which would be very remarkable, and which, so far, has not been accounted for. It shows, however, that this conjoint or conjugate pathologic condition is common if not general—much more so, indeed, than has been supposed or admitted; and if this changeability is proved or admitted, then a common bacillary origin must also be admitted. And the question that would chiefly concern this inquiry would be whether the same morbid material, whether bacillus or other infection, missing the lungs in its ingress, can pass on and set up in the kidneys the same pathologic process, produce an organic lesion such as it would have developed if it had obtained a lodgment in the lungs, or if the same lesion, having been eradicated from the lungs, is capable of being fully reproduced in the kidneys. I know of no answer to these questions from present knowledge. Clinically speaking, we make a wide difference in the treatment of the two affections—chronic nephritis and pulmonary tuberculosis—we treat them as quite distinct and separate diseases, and from very different standpoints, and without reference to any apparent similarity, either in origin or symptoms. The question would come up later, whether or not we should employ the same therapeutics for both diseases, and what would be the result of such treatment.

RECENT ADDITIONS TO THE MATERIA MEDICA.

By W. A. N. DORLAND, M.D.,
INSTRUCTOR IN GYNECOLOGY, PHILADELPHIA POLYCLINIC.

In preparing this review of the more recent additions to the materia medica, the main difficulty has consisted rather in the selection, out of the embarrassment of material at hand, of those remedies that have been proved of real worth, than in any lack of material from which to draw. Care has been taken, so far as was possible, to throw aside all drugs of doubtful merit, in order that room might be given to those that experimental and clinical therapeutics have demonstrated to be valuable acquisitions to the materia medica of the day. Following in the wake of the rapid strides that are being made in organic chemistry, these newer remedies are necessarily largely synthetic in character. Only a few are the result of botanic research.

Antisepsin, $C_6H_4BrNHC_2H_3O$. Para-mon-brom-phenyl-acetamide, or bromated antifebrin, occurs as tasteless, odorless crystals, melting at 328° F., insoluble in cold water, and with difficulty soluble in hot water, slightly soluble in glycerin, but readily so in alcohol and ether. In large doses it gives rise to evanescent cyanosis, and will produce death by paralysis of respiration. Applied to wounds and ulcers in the form of a powder, rapid improvement ensues, the granulations flattening and cicatricial centers appearing, with relief of pain and itching. In its analgesic action it resembles antifebrin. It is also an antipyretic. *Dose*—one grain, four times daily. *Antipyretic, analgesic.*

Antithermin, $C_6H_5N_2HC - (CH_3) - CH_2COOH$. Phenylhydrazin-levulinic acid, a coal-tar derivative, allied to antipyrin, but feebler in action, is prepared by the direct combination of phenylhydrazin with aceto-propionic acid. It occurs as colorless crystals, insoluble in water, and with difficulty soluble in alcohol. It has been found to reduce temperature by diminution of heat-production with increased heat-dissipation, but its administration is likely to give rise to gastralgia; hence it is not much used. *Dose*—from 4 to 8 grains, in pill or wafer. *Antipyretic, analgesic, antiseptic.*

Aseptol, $C_6H_4OHSO_3OH$. Sulphocarbolic acid, orthophenol, sulphonic acid, sozolic acid, or sulphobenzidic acid, as it is variously termed, is prepared by the direct combination of carbolic acid and concentrated sulphuric acid. It occurs as a heavy, syrupy, reddish liquid, with an astringent taste and a slight odor of phenol, an acid reaction and a specific gravity of 1.400. It crystallizes in small deliquescent needles, which are very soluble in water, alcohol, and glycerin; a 33 per cent. solution is recommended in preference to carbolic acid as an antiseptic, being less caustic than the latter, and hardly at all toxic. Tucker regards it as a weaker antiseptic than carbolic acid. A 3 per cent. solution has been recommended in gingivitis and pyorrhea; under its action the swelling is reduced, the flow of pus arrested, and the gums restored to their natural condition. It may be advantageously employed for some time in affections of the skin, eye, and bladder. Internally it may be exhibited in relatively large doses in the treatment of pharyngitis and dipbtheritic laryngitis. *Dose—internally* Vigier employs a lemonade in the proportion of a dram and a half of aseptol to a quart of water; *externally*, a solution of from 1 to 10 per cent. *Antiseptic.*

Benzo-naphthol or naphthol-beta benzoate, $C_{10}H_7O(C_7H_5O)$ is prepared by combining benzoic acid with naphthol-beta, and occurs as a whitish, crystalline, odorless, and tasteless powder, melting at 110° C., almost insoluble in water at ordinary temperature, very slightly soluble in ether, more so in alcohol, and readily soluble in chloroform. It has but slight toxic effects, and its antiseptic properties are comparable with those of any other

substance in use as an intestinal antiseptic. In the body it is broken up into naphthol-beta, which remains in the intestinal tract, and benzoic acid, which is eliminated in the urine after having formed alkaline hippurates. It favors diuresis and markedly diminishes urinary toxicity. Burton has used it with marked benefit in typhoid fever and tuberculous bowel-ulceration. *Dose*—daily 75 grains to an adult, 30 grains to a child, administered in from 2 to 8 grain doses in a cachet or suspended in a vehicle. *Intestinal antiseptic.*

Benzosol, $(O.COC_6H_5)C_6H_4(O.CH_3)$. Benzoyl-guaiacol, which is prepared from guaiacol, is an agreeable and harmless substitute for creasote in tuberculous affections. It occurs as a white crystalline powder, tasteless, with a faint bitter-almond odor, almost insoluble in water, soluble in ether and chloroform. It is decomposed in the digestive tract into guaiacol and benzoic acid, and the former is eliminated in the urine and saliva within half an hour after ingestion. It exerts a beneficial influence upon the general nutrition and consequently increases the resistance of the patient to the disease. It is also recommended as an antipyretic and antiseptic. *Dose*—from 4 to 10 grains by the mouth; as it is decomposed by hot water it must be exhibited in powder form. *Antituberculotic, antipyretic, antiseptic.*

Bromamide, $C_6H_2Br_3NH.HBr$. A bromine-compound of the anilide group, containing 75 per cent. of bromine. It occurs as colorless, acicular crystals, almost odorless and tasteless, melting at 243° F., and volatilizing at 310° F. without change, subliming in beautiful, feathery crystals. It is insoluble in benzine and hot or cold water, slightly soluble in cold, and more so in boiling alcohol, readily soluble in chloroform, ether, and the fixed oils; its solution is neutral in reaction. It has been adminis- as an antipyretic and antineuralgic in typhoid fever, acute and chronic articular rheumatism, rheumatic fever with acute endocarditis, chronic nephritis with dropsy, and various forms of neuralgia, and has been found to have the power of reducing the temperature in most febrile diseases from 1° to 2.5° F., without producing excessive sweating. It has no pronounced diuretic action, and is free from any unpleasant symptoms as regards the digestive tract. *Dose*—to adults, from 10 to 15 grains several times in the day; to children, from 1 to 5 grains. It may be given in capsule or wafer, dry, upon the tongue, or suspended in a fluid. *Antipyretic, antineuralgic.*

Burra Gookeroo. The spring carpels of *Tribulus lanuginosus*, a plant belonging to the typophyllaceæ or guaiacum order, and growing extensively throughout the East. It has been used largely as a diuretic, and has also been employed as a remedy for the relief of nocturnal emissions. It is possessed of tonic and aphrodisiac properties, and has been found to exert a beneficial effect in gonorrhea and dysuria. In the form of the infusion or decoction it has been employed, together with other remedies, for painful micturition and impotence. *Dose*—of the fluid extract, from 20 to 50 minims; of the infusion, from 1 to 2 drams; of the syrup, which is an excellent form of the drug for administration to children, from ½ to 1 dram. *Diuretic, aphrodisiac.*

Chinolin (*Quinolin*), C_9H_7N, is prepared synthetically from aniline, nitrobenzol, glycerin, and sulphuric acid, but may also be obtained as a derivative of cinchonine and quinine by dry distillation. It is a transparent, oily liquid, slightly tinted, with a peculiar, penetrating odor, slightly soluble in water, but freely so in alcohol, ether, and oils. Its color deepens on keeping. The *tartrate*, being more soluble, is better adapted for use in medicine. It occurs in odorless, white crystals, with a nauseating taste, soluble about one in forty of water. Chinolin is a powerful antiseptic and antipyretic. Internally it is used in enteric fever and in intermittent fever, and in periodic neuralgias. An aqueous solution forms an excellent antiseptic injection for gonorrhea, while it is highly recommended as a gargle for diphtheria in the following formula: One part of chinolin in 50 of rectified spirit and 500 of peppermint water. A solution of 4 scruples of chinolin in 3½ ounces of alcohol may be applied with a brush to the diphtheritic membrane. *Dose*—of chinolin, from 3 to 10 minims; of the tartrate, from 5 to 15 grains. *Antiseptic, antipyretic.*

Chlorethyl, C_2H_5Cl. Mono-chlor-ethane or ethyl chloride, is prepared by saturating an artificially cooled alcoholic solution of zinc chloride with hydrochloric acid gas. At ordinary temperatures it exists as a gas, but it may be readily compresed into a colorless, mobile liquid, with a pleasant etheral odor and a sweetish, burning taste, a specific gravity of 0.9214, boiling at from 50° to 53.6° F., and burning with a green flame. It is slightly soluble in water, but readily so in alcohol. Owing to its low boiling-point it is admirably adapted to the rapid production of local anesthesia, and for this purpose it is furnished in glass tubes holding ten grams of the fluid. When used, the end of the tube is broken off and the latter held at a distance of from six to ten inches from the spot to be anesthetized, thereby avoiding excessive and useless cold. Chlorethyl is of service in all forms of minor and dental surgery and in the treatment of facial and intercostal neuralgias. Its only drawback is its great inflammability. *Local anesthetic.*

Chlorphenol, $C_6H_4Cl.OH$. Mono-chlor-phenol is a very volatile fluid with a vapor heavier than air. It is possessed of marked antiseptic and antituberculotic properties. When applied to wounds, ulcers, and discharging glands remarkable improvement follows. It has been strongly recommended for inhalation in diseases of the respiratory passages. Ozena, laryngitis, bronchitis, and more particularly tuberculous affections are beneficially influenced after commencing the inhalations. The bacilli rapidly disappear from the sputum, the cough diminishes, fever is reduced, appetite and sleep soon return, and the body-weight increases. Passerini has thus treated five cases of tuberculous disease of the lungs, all recovering in from two to six months from the beginning of the treatment. The inhalations are easily borne in advanced pulmonary tuberculosis, no injurious effects arising from their continuous use. *Antituberculotic, antiseptic.*

Cineraria Maritima. Freshly expressed juice of the leaves is employed in the treatment of cataract without operation. Its use occasions no irritation or inflammation beyond a slight sense of burning pain that lasts for a minute or two. Several reports of steady improvement following its employment are noted, and one case is quoted in which a cure was affected in two months. *Dose*—2 minims, to be dropped into the eye three times daily.

Dermatol, $C_6H_2(OH)_2.CO_2Bi(OH)_2$. Bismuth subgallate is an extremely fine, non-hygroscopic, odorless, saffron-yellow powder, stable in air and light, insoluble in ordinary solvents. On account of its insolubility, its antibacterial action is limited to the area in which it comes in contact with the pus-microbes, the drug in this respect resembling iodoform. In addition to its direct antiseptic action, it has a desiccating influence, so that the development of bacteria is inhibited by the drying of their pabulum. Dermatol gives rise to no irritation and is not absorbed. It has been largely used in surgery, dermatology, and gynecology. It is of special service in affections or lesions associated with copious secretion. Under its influence the secretion rapidly diminishes. It is effective in purulent affections of the eye and ear; ulcers of the legs and feet that have resisted all other treatment promptly yield to it. Glaeser, of Breslau, reports favorably of it as an application for superficial wounds. In various skin-affections a 10 per cent. ointment with vaselin or lanolin, or a powder diluted with starch or talc may be employed. The following formula may be employed as an ointment: Bismuth subgallate, 10 parts by weight; vaselin, 10 parts; and lanolin, 80 parts; to be applied to ulcerations. Dermatol is not as serviceable in local tuberculous affections as iodoform, nor should it be used on torpid wounds and ulcers, for which stimulating remedies are indicated, nor in fresh phlegmonous wounds and freshly-opened abscesses. *Internally*, it is said to be of value in affections of the stomach and intestines. It is non-poisonous and well borne. *Dose*—two drams daily. *Antiseptic.*

Disinfectol. A substance analogous to creolin and lysol. It is a brownish-black, oily liquid, having a specific gravity of 1.086, and with an alkaline reaction. It contains hydrocarbons, soaps of resin, and combinations of soda and carbolic acid. It has very energetic disinfectant properties, and is used in the form of from 2 to 5 per cent. emulsion. *Disinfectant.*

Diuretin is a double salicylate of theobromine and sodium, containing 50 per cent. of the former. It is a white powder, with a very bitter taste, freely soluble in water. It is very unstable, and is decomposed by all acids, even by CO_2 of the atmosphere. Internally it causes no irritation of the stomach or kidneys; nor does it increase arterial tension. It has been found useful in pleuritic effusion, its diuretic action usually manifesting itself within the first twenty-four hours. No cumulative effects have been observed, but occasionally a slight diarrhea is produced. Under its influence, dyspnea, bronchitis, and anorexia, together with the general condition, are improved. When administered in acute nephritis, the quantity of urine voided is greatly increased. It decreases cardiac dropsy and strengthens the pulse. *Dose*—90 grains daily in 15-grain doses. It is best administered in cachets, or as a clyster, dissolved in lime-water to prevent interference with its action by the gastric juice. It may be given in solution in warm water, or in gelatin-coated pills. The bitter taste may be disguised by the addition of some aromatic oil. *Diuretic.*

Ethylene Bromide, $C_2H_4Br_2$. A light brownish-colored liquid with an odor resembling that of chloroform, and a taste sweetish at first, but afterward burning. Its specific gravity is 2.163, and it contains 90.9 per cent. of bromine. It is insoluble in water, but readily mixes with alcohol and oil. It boils at 300° C., and at the freezing-point solidifies into a snow-white crystalline mass. It has been used with great benefit in epilepsy, the convulsive attacks under its influence becoming rarer, shorter, and milder. *Dose*—from ¼ to 2¼ minims two or three times daily. It may be administered in milk, according to Donath, his favorite formula being: Ethylene bromide and spirits of wine, of each 32 minims; oil of peppermint, 2 minims; of this from 5 to 15 drops may be administered two or three times daily. A 5 per cent. emulsion may be employed thus: Ethylene bromide, 35 minims; emulsio oleosa (containing two parts of expressed oil of almonds, one part of powdered acacia, seventeen parts of water), 3¼ ounces; oil of peppermint, 2 drops. Of this, adults take 30 drops in a small wineglassful of sugar-water twice or thrice daily, increasing the dose every third day successively to 40, 50, and then 70 drops. A child of eight or ten years should begin with from 10 to 20 drop doses twice daily. An oily solution may be used subcutaneously. *Anti-epileptic.*

Eucalyptol is composed of 6 parts of salicylic acid, 1 part of carbolic acid, and 1 part of essence of eucalyptus. It possesses an aromatic odor and a burning taste, is almost insoluble in water, but is soluble in alcohol, chloroform, ether, glycerin, alkaline solutions, and ammonia. It is said to be an excellent dressing for wounds, since it does not produce albuminates, which inhibit antisepsis. Internally, it may be administered in acute rheumatism, typhoid fever, pulmonary catarrh, and affections of the urinary passages. *Dose*—from 2 to 2½ drams per diem. *Antiseptic.*

Euphorin, $C_9O_2H_{11}N$. Phenylurethane, or ethyl phenylcarbamate, is prepared by the action of chloroxycarbonic acid upon aniline. It occurs in fine white needles, with a slightly acrid taste, melting at 52° C. It is sparingly soluble in cold water, and slightly so in boiling water, but is soluble in all proportions in alcohol and ether. It is recommended as a safe and rapid antipyretic, the antithermic action being due to dilatation of the peripheral vessels, with elevation of the peripheral temperature, and at the same time a diminution of the central temperature. Its action is attended with profuse sweating and flushing of the surface. It has no influence upon the normal temperature. It is largely consumed in the body, only a small portion being eliminated in the urine as para-oxyphenylurethane. Santoni regards it as an energetic antipyretic without any attendant danger, and exerting a favorable action upon the general condition. It has also been employed as an antirheumatic, and successfully by F. Adler in pulmonary tuberculosis. As an analgesic it has been largely used in the various forms of neuralgia, and in ovarian and uterine pains. According to Oliva it is a true antiseptic, being as efficient as iodoform. G. Peroni has used it in dermatologic practice in powder or alcoholic solution (from 10 to 50 to 100) or in the form of a pomade with lanolin. He has used it successfully in lupus, burns to the second degree, herpes zoster, seborrhea, eczema, and syphilitic ulcers. It corrects unpleasant odor; granulations become healthy; and the diffusion of venereal virus is hindered. No toxic effects

are noted. *Dose*—from 5 to 30 grains daily, in medicated cachets, in solution in white wine, or suspended in a mucilaginous potion. *Antipyretic, analgesic, antiseptic.*

EUROPHEN. Isobutylorthocresol iodide, a preparation of iodine, occurs as an amorphous, fine, yellow, somewhat sticky powder, which should be protected from light and moisture. It has a moderately strong aromatic odor, is insoluble in water and glycerin, but readily soluble in ether, alcohol, chloroform, and oils. It is five times lighter than iodoform, and possesses the same anti-tuberculous effect. It adheres readily to the skin and to wounds, and is excreted in the urine in the form of iodine. Insufflations of europhen promptly cause the healing of chancroids and chancres. Europhen may also be used hypodermatically in syphilis, a 1 per cent. solution in olive oil being employed, of which from 7 to 15 minims are injected daily. In tuberculous abscesses, injections of a glycerin emulsion may be used. From 5 to 10 per cent. ointment is recommended in skin-diseases. *Antiseptic, antituberculotic.*

EXALGIN, $C_6H_5NCH_3C_2H_3O$. Methylacetanilid, a benzene derivative allied to phenacetin, occurs as colorless, slightly bitter needles, or large tablets; it is slightly soluble in cold water, more so in hot, and freely in dilute alcohol. It is a valuable analgesic, and also an antipyretic and antiseptic, but to a less degree. In toxic doses it produces trembling and paralysis of the respiration, with collapse. It causes diminution in the quantity of urine and of sugar in diabetes, and has been suggested for employment in influenza. *Dose*—from ½ to 4 grains, not exceeding 14 grains, in twenty-four hours. It may be given in the form of a mixture, 5 grains to the ounce, or in an effervescing salt, 8 grains to the ounce—1 dram being the dose. *Analgesic, antipyretic.*

FUCHSIN, $C_{20}H_{10}N_3.HCl$. Rosanilin hydrochlorate, or anilin red, occurs in brilliant elongated crystals having a green luster, readily soluble in water, and forming a bright-red solution. In toxic doses it produces salivation, vomiting, diarrhea, and yellow vision. It is excreted by the kidneys, liver, and salivary glands; imparts a yellow color to the urine and stools; is efficient in reducing albuminuria and in retarding the growth of carcinoma. Bogroff advocates its use in chronic tuberculous laryngitis and pharyngitis, employing for this purpose a spray of 2 per cent. boric acid solution saturated with fuchsin. The spray forms an impermeable layer over the epithelial lining, and shields the tissues from further irritation. *Dose*—from ½ to 4 grains, best administered in pill with a vegetable extract, such as gentian or licorice. *Antimycotic.*

GALLACETOPHENONE, $CH_3CO.C_6H_2(OH)_3$. Prepared by treating pyrogallic acid with acetic acid in the presence of zinc chloride. It is a light yellowish powder, which readily crystallizes in yellowish needles, soluble in hot water, alcohol, ether, and glycerin, and absolutely innocuous. It is a most efficacious antimycotic, and of pronounced value in psoriasis and similar skin affections. It is used as a 10 per cent. ointment, applied twice daily, and acts more promptly than chrysarobin, and without discoloration of skin or linen. *Antimycotic* and *in dermatology.*

GUAIACOL, $C_6H_4OH.OCH_3$. The methyl ether of pyrocatechin, obtained by the destructive distillation of guaiacum resin or beech tar. It is a colorless liquid, with a taste and odor similar to, but more agreeable than, those of creasote; it is soluble in alcohol, ether, and oils, but only slightly so in water; it boils at 392° F.; it has a specific gravity of 1.1171. It should be kept in dark bottles, protected from the light. Guaiacol has been much used as a substitute for creasote in pulmonary tuberculosis, administered with cod-liver oil, which disguises its taste. It has been recommended for tuberculous diarrhea in the form of the following enema: Guaiacol, 10 drops; olive oil, 6 drams; water, 8 ounces; yolk of one egg. Schueller frequently administers it by inhalation, employing for this purpose weak aqueous solutions (5 : 3000 to 5000). These inhalations must be constantly controlled by the physician, and over-exertion in inhaling must be strictly avoided. General improvement follows. It has also been successfully employed in so-called surgical tuberculosis in the form of an aqueous solution, in combination with a 10 per cent. iodoform-glycerin solution, injected at the seat of the disease. Lupus and tuberculous joint-disease have been so treated with marked success. As an antipyretic a solution containing from 5 to 7 per cent. of guaiacol in almond oil may be injected hypodermatically in doses of from 15 to 20 minims per diem. *Dose*—from ½ to 2 minims in pill or capsule. *Antituberculotic, antipyretic.*

HYDRACETIN, $C_6H_5N_2H_2(C_2H_3O_2)$. Acetyl-phenylhydrazin is a white, odorless, almost tasteless, crystalline powder, derived from coal tar; it is soluble in 50 parts of water, and freely so in alcohol, chloroform, and benzine; it fuses at 262.4° F. It is a powerful antipyretic, and must be administered with caution, and not continuously, as it very readily produces toxic effects—cyanosis of the face, chills, profuse sweats, arrest of pulse and respiration, and collapse. Conti considers it a powerful blood-poison with a destructive action upon the red blood-corpuscles, analogous to that of potassium chloride. A 10 per cent. ointment has been used with success in psoriasis, but the effect must be watched. *Dose*—from ½ to 2 grains daily, in one or two doses. *Antipyretic, analgesic.*

IODO-NAPHTHOL-BETA. Naphthol-beta diiodide is prepared by the action of iodine on naphthol-beta, and occurs as an inodorous, tasteless, greenish-yellow powder, insoluble in water, slightly soluble in ether, alcohol, and acetic acid, but freely soluble in chloroform. It has been suggested as a substitute for iodoform in the dressing of wounds and ulcers. *Antiseptic.*

IODOPHENIN is formed by treating a cold, saturated solution of phenacetin, acidulated with HCl, with iodine. It occurs as a chocolate-brown powder, or in steel-blue crystals after recrystallizing from glacial acetic acid, possessing an acrid, burning taste, and a feeble odor of iodine; it is insoluble in water, slightly soluble in benzol and chloroform, more so in hot glacial acetic acid, and freely soluble in alcohol; it melts at 266° F., decomposing at the same time. Wittkowsky has found that iodophenin is a most efficient bactericide, but Siebel concludes that no specific action can be ascribed to it that iodine itself does not exert. The objection to its use is its strong evolution of iodine. Introduced subcutaneously, it causes inflammation; taken internally, it affects the digestive tract, and iodine intoxication is possible even after small doses. *Antiseptic.*

Iodopyrin, $C_{11}H_{11}INO_2$, is a chemical compound of iodine and antipyrin, in which one atom of hydrogen is replaced by one of iodine. It is a tasteless and odorless powder, slightly soluble in cold water and alcohol, but readily soluble in hot. Munzer has used it in typhoid fever and pulmonary tuberculosis. "Five cases of typhoid fever are recorded, and in each instance the temperature was rapidly lowered to normal. In cases of pulmonary tuberculosis the administration of the drug caused profuse sweating, and in every way the antipyretic action was all that could be desired." When taken into the stomach, iodopyrin is decomposed into iodine and antipyrin. *Dose*—from 1 to 5 grains. *Antipyretic.*

Lysol is a saponified phenol derived from cresols by the action of nascent soap. It occurs as a dark-brown, syrupy liquid with a faint aromatic odor; it is freely miscible with water and alcohol, forming a clear solution which lathers when agitated; its specific gravity is 1.042. It is possessed of powerful deodorizing properties, and has been introduced as a soluble antipyretic and disinfectant. All agree that it is superior to the disinfectants commonly in use, possessing, as it does, higher antimycotic powers than carbolic acid or creolin, while it is less variable in constitution than the latter, and less poisonous than either. It produces marked improvement in lupus when applied freely by means of a cotton probe, after removal of the crusts, and allowed to dry, the application being repeated daily, or every second day. The pain of the application is acute for one-half hour, but entirely disappears in two or three hours. Dr. Unna has used lysol in the form of a plaster mull, and appears to have been favorably impressed with it; in this form it is nearly painless. Intra-uterine and vaginal injections have been repeatedly made without any toxic effects. Michelsen has used a ½ per cent. solution in twelve cases of celiotomy with the happiest results, healing by first intention following. It has also been used in the same strength in abortion. Szuman advises a ½ per cent. solution for irrigation of the pleural and peritoneal cavities. In the bladder it gives rise to vesical pain and tenesmus. Höffler recommends a 2 per cent. solution in diphtheria, and Gerlich employs it in the following prescription as a gargle for foul breath or diseased conditions of the mouth and throat: Lysol, 2.5 grams; water, 50 grams; alcohol and glycerin, each 25 grams. It acts as an efficient general disinfectant for the walls of a room by spraying with from a 1 to 3 per cent. solution, while for the hands, sutures, instruments, irrigation, and field of operation from 1 to 2 per cent. solution suffices. *Antimycotic.*

(*To be continued.*)

HOSPITAL NOTES.

CASES FROM THE CLINIC OF PROFESSOR J. M. DA COSTA,

At the Jefferson Medical College Hospital.

[Reported by Augustus A. Eshner, M.D., Clinical Recorder.]

TWO CASES OF GASTRO INTESTINAL NEUROSIS, WITH PECULIARLY INDUCED BOWEL-MOVEMENTS.

H. S., a salesman, thirty years old, for as long as he could remember had had from two to thirty stools daily. The stools were usually small, thin, and slimy, and occasionally blood-streaked; less commonly they were normal. The ingestion of liquids was invariably followed in from twenty to thirty minutes by a watery intestinal evacuation. Solid food occasioned no excess of movements. There was occasionally a desire to have the bowels moved, with ineffectual efforts at stool. The appetite was good. Digestion was attended with no discomfort. The patient alternately lost and regained weight. The urine had a specific gravity of 1036; it contained a precipitate of urates, but neither albumin nor sugar.

There was a history of prolapse of the bowel from birth or infancy, but this had corrected itself without therapeutic intervention, and for four years had occasioned little or no inconvenience.

The patient was given a pill containing an eighth of a grain each of silver nitrate and belladonna extract, to be taken after each meal, and he was told to restrict the use of liquids as much as possible. He returned in the course of a short time, reporting himself, even when on mixed diet, as cured; but he failed to present himself again, and the ultimate result is not known.

A. L. H., a girl, aged twenty-four years, who lived at home, complained for four years of severe colicky pain in the abdomen of progressively increasing intensity, invariably following the ingestion of food — less after liquids than after solids, and often occurring after the mere smelling of food. After taking food the abdomen became distended, and in the course of five minutes there was an urgent desire to go to stool. The stools were usually liquid, but were never observed to contain blood. The movements of the bowels were attended with pain and bearing down. The frequency of movement was not perceptibly influenced by restriction to a liquid diet. The bowels were never moved unless food or drink was previously taken. The appetite was preserved. Occasionally a greenish, bitter fluid was vomited in considerable quantity; blood was never vomited. There were flatulent eructations, but little loss of flesh and of strength was noticed. Menstruation was painful and was attended with headache.

The urine was of acid reaction; it had a specific gravity of 1034, and contained neither albumin nor sugar.

The patient was placed upon a pill of silver oxide, gr. ⅓, and opium extract, gr. ⅙. The ultimate result of this case could not be ascertained.

PHANTOM-TUMOR AND VALVULAR HEART-DISEASE.

A. R., a girl, aged fifteen years, had for four years observed an enlargement in the epigastric region, which progressively increased in size. The tumefaction was inconstant in size but was never wholly absent, and was generally as large as a child's head and attended with pain. Menstruation had previously been profuse, but was now absent. The appetite was impaired, but there was neither nausea nor vomiting. Obstinate constipation existed, and there had been slight loss of flesh. No hysterical symptoms had been manifested.

On examination, a tumor was found in the epigastrium, prominent, tender to the touch, and dull on percussion. The mass was influenced by the position of the patient and could be made to disappear by strong

flexion of the thighs on the abdomen. When the thighs were flexed the dulness on percussion gave way to a tympanitic note. The mass also disappeared when respiration was checked at the end of expiration; the sensitiveness, however, persisted. The heart was enlarged and overacting. A harsh, blowing, systolic murmur was heard in the mitral area. The urine was acid in reaction; it had a specific gravity varying from 1018 to 1022, and contained neither albumin nor sugar.

The valvular disease of the heart rendered it risky to administer ether with a view to ascertain the exact nature of the tumor. The results obtained by the forced flexion of the thighs on the abdomen, relaxing the upper portion of the recti and causing the tumor to disappear, were, therefore, especially valuable.

The following prescription was given:

℞.—Aloin . . . . . gr. ij.
Pulv. capsici . . . . gr. ij.
Ext. belladonnæ . . . . gr. j.—M.
Ft. pil. no. xvi.
S.—One to be taken three times a day.

One drop of tincture of aconite three times a day was also prescribed.

The improvement was most decided. The abnormal abdominal manifestations ultimately entirely ceased.

TWO CASES OF ARTERIAL THROBBING SIMULATING ANEURISM.

A. M. K., a housekeeper, aged fifty years, had been told that she had an aneurism. For more than four years she had observed palpitation of the heart and shortness of breath on exertion. Eighteen months before coming to the clinic she had noticed throbbing in the supra-sternal notch, which, under treatment, had become less decided. For sixteen months there had been irritative, "rasping" cough, which had also become less frequent and less distressing. The patient perceived a sound like the ticking of a watch, referred to the right sterno-clavicular articulation. There was no difficulty or pain in swallowing. Laryngoscopic examination detected no abnormality. The appetite was impaired and the digestion deranged. The face flushed on excitement—on both sides equally. There was subjective impairment of vision on the right side, with doubtful contraction of the visual field. The right pupil acted in convergence, but failed to respond to light. No lesion of either fundus was found. The patient stated that fifteen years previously the right eye was "paralyzed." No history of syphilis was elicited.

At the root of the neck there was evident throbbing. There was no pulsation in the chest. At the aortic cartilage a systolic murmur was heard, followed by a distinct second sound. The impulse of the heart was extended. The first sound at the apex was heavy. The pulses were equal. The urine was acid in reaction; it had a specific gravity of 1022 and contained neither albumin nor sugar.

Two drops of tincture of aconite three times daily were prescribed. The patient returned but once, reporting that the sense of beating had become much less decided.

J. M., a salesman, aged twenty-four years, for a year had felt a sensation, vaguely described as "jumping," a little to the left of the median line between the level of the umbilicus and that of the ensiform cartilage. It was least noticeable in the recumbent posture, most so when erect, and was intensified by active exercise. There were also palpitation of the heart, ringing in the ears, disturbance of sleep. The appetite was variable, and languor and drowsiness followed meals. The bowels were irregular. The man was concerned about himself and had lost twelve pounds in weight. He had never received a blow in the abdomen, but for a period of thirteen years he had had frequent occasion to employ the abdominal walls in making pressure. He used tobacco to excess. There was no history of venereal infection.

On examination, a pulsating area, as large as a man's fist, was found between the umbilicus and the ensiform cartilage. On auscultation, a systolic murmer, intensified by pressure, was heard in the epigastrium. No murmur could be heard in the back; nor was there pain in the back. The temporal arteries were large. The heart was acting strongly. The pulse was full and tense. The urine had a specific gravity of 1030; it contained neither albumin nor sugar.

The patient was given the following prescription:

℞.—Tinct. capsici . . . . gtt. xxiv.
Tinct aconiti . . . . gtt. xlviij.
Tinct. cinchonæ co. . . ad f℥iij.—M.
S.—A teaspoonful to be taken three times a day.

The patient returned improved, but seen at a later date the symptoms had returned to their previous intensity.

In both of these cases the throbbing simulating aneurism was the result of the disease of the heart; in the first case hypertrophy with aortic narrowing, in the second case simple hypertrophy in a nervous man, in whom very likely, too, the local pressure on the abdomen aggravated the throbbing. In the diagnosis of the second case the absence of pain was very significant; in the first case, the absence of pressure-symptoms.

THREE CASES OF VISCERAL SYPHILIS: PULMONARY SYPHILIS; PULMONARY AND HEPATIC SYPHILIS; CEREBRAL SYPHILIS.

PULMONARY SYPHILIS.

H. L. S., a clerk, aged twenty-five years, presented a history of winter cough for many years. Three years before coming under observation he had been infected with syphilis. For three months he had had persistent cough, with mucous but never hemorrhagic expectoration. He had lost fifteen pounds in weight, and had been in bed with what was said to have been malarial fever. There were irregular and infrequent chills, and for a time there had been night-sweats. The sputum was examined, but tubercle-bacilli were not detected. Ophthalmoscopically, nothing abnormal was noticed in either fundus. Laryngoscopic examination disclosed no evidence of syphilitic or tuberculous disease.

There was a history of pulmonary tuberculosis in the father and paternal grandmother. Irregular and scattered areas of percussion-dulness were found upon both sides of the chest, with harsh inspiratory and prolonged expiratory murmur.

The patient was placed upon potassium iodide and mercuric chloride; he was for a time also given cod-liver oil with malt. Under this treatment he progressively improved.

The following is a record of his weight:

September	120	pounds.
December 12th	127¼	"
December 24th	128¼	"
January 1st	130	"
January 9th	131	"
January 15th	130¾	"
January 30th	130	"
February 20th	131½	"

PULMONARY AND HEPATIC SYPHILIS.

O. S., a waiter, aged thirty-five years, had for six years complained of palpitation of the heart, shortness of breath, and precordial pain. For five years and a half he had had pain and tenderness in the epigastrium and vomiting. Five years before coming under observation he lost consciousness, and, as he was told, lay in convulsions, the face, lips, and hands being blue. This attack was not followed by palsy. Six months later the feet, hands, and eyelids were swollen for two months and a half; the swelling occasionally recurred thereafter. A second attack of unconsciousness, with convulsions and cyanosis, occurred a year and a half after the first. For three years there was cough, with scanty expectoration; there had never been hemoptysis. The man had lost twelve pounds in weight. He gave a history of syphilitic infection fourteen years before appearing at the clinic, and had been told that five years previously he had had bilateral pleurisy with effusion.

On palpation, a smooth, resistant, non-fluctuating tumor of peculiar shape was found extending to the umbilicus on the right and an inch and a half below the umbilicus. The area of hepatic percussion-dulness extended just below the margin of the ribs laterally. The mass seemed to project below and to pass lower down. There was also considerable dulness on percussion and resistance in the epigastrium, with tenderness. The upper border of the liver was difficult to map out on account of the dulness on percussion over the lung. The lungs were dull on percussion in areas of irregular size and distribution. On respiratory percussion the pulmonary resonance was elicited. The area of hepatic percussion-dulness was thus found to begin at the fifth intercostal space. There was percussion-dulness at the apex of the right lung, as well as bronchial breathing. Râles were not heard. Vocal resonance and fremitus were increased. There was substernal tenderness. No eye-lesion existed. The urine was acid in reaction and contained neither albumin nor sugar. One-twenty-fourth of a grain of mercuric chloride and ten grains of potassium iodide were directed to be taken three times daily, but the patient failed to return, and the result of treatment is not known.

CEREBRAL SYPHILIS.

M. B., a messenger, thirty-seven years old, had for three months, principally after noon, suffered with a sense of heaviness in the head and a tendency to stagger. The gait was unaltered; the station was firm; there was no ataxia. The knee-jerks were preserved. There was no gross derangement of sensation and no history of crises. The special senses and mental functions were subjectively unimpaired. There was no headache and no vertigo. The appetite was preserved. Digestion was well performed; the bowels were regular. There was no derangement of micturition. Neither cough, expectoration, shortness of breath, loss of flesh, nor chills, fever, or sweats were noticed. The action of the heart was regular; the sounds clear. The urine contained neither albumin nor sugar. On ophthalmoscopic examination evidences of optic neuritis were found, without limitation of the visual field and without scotomata. Six years previously to coming under observation the patient had had a single venereal sore on the penis, followed by unilateral enlargement of the inguinal glands; other secondary symptoms were not recognized.

The patient improved greatly upon treatment by means of mercuric chloride, gr. $\frac{1}{10}$ (subsequently increased to gr. $\frac{1}{24}$) and potassium iodide, gr. x (subsequently increased to gr. xv), three times daily.

A CASE OF PULMONARY TUBERCULOSIS AND MALARIAL FEVER.

G. C., a salesman, forty years old, presented himself at the clinic with a distinct history of malarial fever seven months previously, and irregular chills, fever, and sweats since. The spleen and liver were enlarged. For five months there had been cough, with muco-purulent, occasionally blood-streaked, expectoration. The man had lost twenty-five pounds in weight and had night-sweats. There was impairment of the percussion-resonance at the apices of both lungs, less marked on the right. At the left apex expiration was prolonged; at the right, the respiratory murmur was harsh.

The urine was acid in reaction; it had a specific gravity of 1026, and contained neither albumin nor sugar.

The patient was ordered a pill containing quinine sulphate, gr. ij, and arsenious acid, gr. $\frac{1}{10}$; and cod-liver oil. He failed to return.

A CASE OF MEDIASTINAL TUMOR.

L. K., a carpenter, forty-six years old, for four months had observed pain at the upper portion of the sternum and in the upper precordial region. For three months there had been a noticeable swelling at the upper portion of the sternum with dyspnea; the latter was relieved by inclining the head forward and was aggravated by the recumbent posture, so that sleep was prevented. There was metallic cough, with scanty muco-purulent expectoration. Deglutition was interfered with and was attended by a sensation of lodgment of solid food at a point about an inch and a half below the upper border of the sternum. A month previously to the onset of the symptoms the patient had been crushed by a heavy weight which he was engaged in lifting. He suffered no immediate distress, nor was he incapacitated for work.

The chest was deformed, the sternum prominent, the lower part of the chest retracted. There was some heaving of the upper part of the chest, but no strong beat or altered sound or murmur existed, and marked pulsation of the vessels of the neck was visible. The cardiac impulse was diffused, but most decided in the seventh interspace, one inch without the nipple line. The pul-

monary percussion-resonance was impaired in the upper lobes, especially on the right side. At the upper part of the sternum was an area of dulness on percussion about two and a half by three and a half inches in extent. At the apex a low-pitched presystolic murmur was heard. The pulses were unequal; the right was the feebler. The urine was of acid reaction; it had a specific gravity of 1026, and contained neither albumin nor sugar.

Under treatment with solution of potassium arsenite the patient gained six pounds in weight. He was subsequently placed upon potassium iodide, but did not do well, and failed to return.

HYPERTROPHY OF THE HEART FROM THE EXCESSIVE USE OF TOBACCO.

W. N., a barber, nineteen years old, had been an excessive smoker of tobacco for eight years, smoking from eight to twelve cigars a day. Three years before appearing at clinic he was seized with a paroxysm of palpitation of the heart, and thereafter the paroxysm had been often repeated. There also had been frequent attacks of vertigo, at times so intense as to cause staggering when he walked along the street. Three months before the patient was seen, after engaging in active physical exercise, he was suddenly seized with hemoptysis, expelling three or four mouthfuls of pure blood. In the following month he had, within a short period, at different times, five further attacks of pulmonary hemorrhage. The last attack had occurred two weeks prior to the appearance of the patient at clinic. The appetite was preserved. Digestion was well performed. The bowels were constipated.

The area of cardiac percussion-dulness was increased, beginning at the right border of the sternum and at the upper border of the left third rib. There was slight relative impairment of the percussion-resonance at the left apex. The vesicular murmur was roughened at both apices, in greater degree on the right.

The urine was acid in reaction; it had a specific gravity of 1020, and contained neither albumin nor sugar.

The patient was put upon the following prescription:

℞.—Sodii bromidi . . . . ʒiv.
Tinct. aconiti . . . . ♏xlviij.
Syrup. zingiberis . . ad fʒiij.—M.
S.—fʒj three times a day, in water.

At the expiration of two months the symptoms had disappeared, the pulse was 84, and the patient considered himself cured, although the physical phenomena of enlargement of the heart persisted.

FOUR CASES OF EXOPHTHALMIC GOITER: ONE IN A MALE; TWO IN GIRLS IN WHOM MENSTRUATION WAS RETARDED AND OTHER NEUROTIC MANIFESTATIONS WERE PRESENT.

C. P., a waiter, thirty-two years old, had for six years suffered with dyspnea and palpitation of the heart, aggravated by exertion or excitement. Only for six months had he noticed protrusion of the eyeballs, which was progressively increasing. The neck was full and presented a distinct swelling at its lower part, which proved to be the enlarged thyroid gland. The carotids throbbed, but presented no murmur. Over the goiter an intermittent murmur was heard. The heart was enlarged and overacting. The first sound was rather dull, the second distinct. The pulse in recumbency was 128. There were headache, vertigo, and tremor of the extended extremities.

The patient gave a history of venereal infection. He was immoderate in the use of tobacco and of alcohol.

The urine was of acid reaction; it had a specific gravity of 1032, and contained neither albumin nor sugar.

Some improvement followed the administration of aconite tincture in doses of from two to five drops, but the patient was soon lost to observation.

M. H., a dressmaker, sixteen years old, had never menstruated, although retarded menstruation was not a family feature. Nine months previously to presenting herself at clinic she had had sore-throat, with enlarged glands. Four months later, she again had sore-throat, also with glandular enlargement. It is thought that the thyroid gland was then enlarged, and that the eyes began to protrude. There was no palpitation of the heart and no tremor of the extended upper extremities. There was shortness of breath, increased on exertion or on excitement. Headache occurred from six to ten times a month. There was no vertigo. The girl was readily frightened. Digestion was well performed. The action of the heart was strong and regular. The pulse was 128. Both lobes of the thyroid gland and the isthmus were enlarged, the left lobe in greatest degree. Over the goiter an almost continuous murmur was heard.

The patient suffered from nocturnal incontinence of urine. A brother, a maternal uncle, and a maternal male cousin, also had nocturnal incontinence of urine.

The mother of the patient presented enlargement of the thyroid gland, which appeared after the birth of her first child and increased with each subsequent birth. The maternal grandmother and great-grandmother, as well as a maternal aunt and grand-aunt, all at one time or another presented goiters. Three sisters of the patient, married and having borne children, present no goiter.

The parents of the patient have noticed changes in her behavior, such as playing with children and walking about the streets when she should have been otherwise engaged.

The urine was of acid reaction; it had a specific gravity of 1024, and contained neither albumin nor sugar.

Tincture of aconite, two drops, and subsequently tincture of strophanthus, from three to five drops, three times a day, were prescribed, with improvement in the subjective condition.

K. D., a cloth-sorter, fifteen years of age, had for more than a year noticed prominence of the eyes, together with "nervousness," restlessness, and irregular jerking movements. The symptoms were much intensified, soon after their appearance, by the death of a sister. For six or seven months it had been observed that the throat was enlarged. From time to time the enlargement underwent additional increase, which sudsided in from twenty-four to thirty-six hours. For a period of six months there had been pain alternating in situation between the precordium and the right mammary region. There had been moderate palpitation of the heart during four months. Saliva was secreted and discharged in excess. The girl complained of thirst and dryness of the throat, and took considerable quantities of

water. For three months there had been frequent epistaxis. Menstruation had not appeared. On several occasions the abdomen had been distended, with attacks of colicky pain. When the upper extremities were extended at right angles to the trunk, the hands were rather over-extended at the metacarpo-phalangeal joints and slightly flexed at the phalangeal joints. There was no tumor, but there were choreoid movements giving rise to a coarse incoördination. The action of the heart was regular; its sounds were distinct; the pulse was 140. The station was firm. The knee-jerks were feeble. The pupils were equal, regular, and responsive to light. There was no nystagmus. The upper lids followed the eyeballs when the patient looked downward. The mental functions and special senses were unimpaired. The appetite was preserved. Digestion was deranged. There was slight cough, with muco-purulent expectoration, but no abnormality was detected in the lungs. The patient was not long enough under treatment to observe any results.

J. C., a housekeeper, fifty-seven years of age, had for two years suffered with palpitation of the heart and a sense of pulsation in the epigastrium. She also complained of weakness and "nervousness." There was tremulousness of the upper extremities. The thenar eminence of the left hand was swollen, and there was also slight swelling on the dorsum of the left hand. The hand was held in partial flexion. The first phalangeal joint of the left ring-finger showed a contracture. There was slight over-extension of the terminal phalanges of both hands, most marked in the middle fingers. There was neither flushing nor sensation of abnormal heat. The thyroid gland was enlarged, in greater degree upon the right. The eyeballs protruded. The extremities were swollen. There was shortness of breath, occasional headache, considerable vertigo, and loss of flesh. The appetite was good; digestion was fairly well performed; the bowels were regular. Sleep was undisturbed. The menopause had taken place ten years previously. The urine was acid in reaction; it had a specific gravity of 1018, and contained neither albumin nor sugar. Tincture of strophanthus, in doses of from three to five drops, was at first administered, but afforded no relief to the distressing palpitation. Subsequently five minims of the tincture of digitalis, with two drams of the infusion of digitalis, in conjunction with one drop of a 1 per cent. solution of nitro-glycerin, were prescribed to be taken thrice daily, but the patient did not return.

THREE CASES OF DIABETES MELLITUS: ONE IN A BOY, NINE YEARS OF AGE; IN TWO OF WHICH AN ODOR OF CHLOROFORM WAS PRESENT; IN ONE OF WHICH THE KNEE-JERKS WERE ABSENT.

C. B. N., a school-boy, nine years of age, was brought to the clinic with a diagnosis of diabetes. Two months previously it was noticed that he was passing unusually large quantities of urine that had a sweetish odor and stiffened the linen on which it dried. There was some weakness of the sphincter vesicæ, with slight incontinence of urine. For five weeks the appetite had been inordinate and the thirst excessive. Though the patient ate and drank largely, he had, however, lost ten pounds in flesh. There were no boils. There had been no itching of the skin. The bowels were regular. The boy was irritable, became readily fatigued, but slept well; no unusual odor was detected. Nothing abnormal was found in heart or lungs. Ophthalmoscopic examination revealed no lesion. There was no family history of diabetes. The urine had a specific gravity of 1042, and contained sugar.

The diet was strictly regulated, and phenacetin (gr. ij) and quinine sulphate (gr. j) in pill, and tincture of the chloride of iron, ten drops, three times a day, were prescribed, but the case did not remain under observation long enough to show the results of treatment.

R. S., thirty-six years old, an oysterman, came to the clinic bringing a specimen of urine, with a diagnosis of diabetes. A little less than nine months previously he had rather suddenly noticed that he was passing excessive quantities of urine, and that he was losing flesh and strength. He had marked thirst, but by restraint he succeeded in restricting the quantity of fluid taken almost within normal limits. He thought that on about two days of seven he passed but little more than the ordinary quantity of urine. The appetite was excessive. Digestion was well performed. The bowels were regular. There was itching of the skin, but no history of boils. A faint odor of chloroform was detected about the patient, of which he was unconscious. Sleep was poor; the patient complained of "nervousness." Vision was subjectively fairly good; there were muscæ volitantes.

The patient denied venereal infection. Fifteen years ago he had an attack of typhoid fever, attended with convulsions. Twenty years ago he was struck in the occipital region by the handle of a revolving crank, losing consciousness for fifteen minutes, and being incapacitated for work for a week.

The urine had a specific gravity of 1036, and contained sugar; albumin was not present.

Fluid extract of jambul was prescribed, beginning with five drops, three times daily, to be progressively increased.

V. L., thirty-nine years of age, a driver of a beer-wagon, presented himself at clinic with a history of over-indulgence in malt liquors, having for a period of six years drunk from ten to fifteen glasses of beer daily. He denied any venereal history. Nine months previously he had had rheumatism for three months. Fifteen years previously he had been wounded by bullets in the left temporal region and on the left lateral aspect of the chest, the bullets, it was stated, being retained. For a year before applying at the clinic he had observed progressive loss of flesh and increasing weakness; he had lost thirty pounds in weight. For two months vision had been failing. The appetite was impaired. The tongue was moist, red, and fissured. For six months there had been persistent thirst. By the patient's statement he drank a pitcherful of water in an hour or two during the morning. During the day he drank considerable milk (several quarts, it was thought) and coffee (two cups); in the evening he took tea. The thirst was so intense that the patient was compelled to arise at night to quench it; otherwise the mouth and throat would become dry and parched. Digestion was well performed. The bowels were regular. There had been no boils and no itching of the skin. The patient slept well. Hearing was lost on the right, following ex-

posure to cold fifteen years previously. The gait was normal. The station was firm. There was no ataxia. The knee-jerks could not be elicited. The pupils were equal, regular, and responsive to light. On ophthalmoscopic examination the discs were found pale, but there was no coarse lesion. The fields of vision were limited in greater degree upon the right. There was central scotoma, especially for red. There was no lesion of the cerebral nerves. An odor of chloroform was perceptible about the patient. He had not observed an increase in the frequency of micturition or in the quantity of urine evacuated, although he arose twice at night to urinate. Measurement, however, disclosed the fact that he was passing from sixteen to nineteen pints of urine in twenty-four hours, the urine containing a large proportion of sugar. He was placed on the usual antidiabetic diet. Treatment with jambul and afterward with sodium salicylate was followed by some but not by permanent improvement.

ABDOMINAL NEURALGIA SIMULATING RENAL CALCULUS.

S. D., a stevedore, forty-one years of age, three weeks before presenting himself at clinic, and shortly after having been engaged in lifting a heavy weight, was suddenly seized with intense lancinating pain in the lumbar region of the spine. The pain radiated to the left and around the abdomen to the umbilicus. The paroxysm was followed by excruciating abdominal cramps. During the remainder of the day, and on the following day, a sense of soreness persisted. Two days later the man suffered a second paroxysm, the pain, however, being umbilical from the outset, radiating to the anterior superior iliac spine and the inguinal region. The attack lasted four hours. Ether and morphine were administered for the relief of the pain. After an interval of four days, a third attack occurred, lasting also for four hours. The pain was referred to the crest of the ilium, and radiated to the anterior superior spine and the inguinal region. There was a fourth attack, lasting twelve hours, the pain occupying the same situation as in the preceding attack. The urine, it was stated, had an offensive odor, but had never contained blood. It had a specific gravity of 1022, and was of acid reaction; it contained neither albumin nor sugar. The patient did not pass gravel. There had never been jaundice. The stools had not been observed. There was general abdominal tenderness.

Belladonna tincture was prescribed for the patient.

PROGRESSIVE MUSCULAR ATROPHY AT AN EARLY STAGE.

F. P., a clerk, thirty-four years of age, five years previously to presenting himself at clinic had observed slight loss of power in using the right hand in writing. The symptom disappeared in the course of two weeks. Two years later the manifestation was repeated. Thereafter there was gradual loss of power in the right arm. For two years there had also been gradual loss of power in the left upper extremity. The chest and the upper extremities were conspicuously wasted. There was no pain, nor was there loss of power in the lower extremities. The patient had lost twenty pounds in weight. There was no cough; no shortness of breath; no palpitation of the heart. Micturition had become increased in frequency; the urine was acid in reaction, had a specific gravity of 1024, and contained neither albumin nor sugar. The heart-sounds and the breath-sounds were normal. There was no increase in the areas of splenic and hepatic percussion-dulness. There was no blue line on the gums. The hands were cyanotic, the right especially. There was wrist-drop on the right side. The station was firm. The knee-jerks were exaggerated. At times tremor became apparent in the extended right upper extremity.

Mild faradic applications to the wasted muscles were advised. The patient, however, failed to appear a second time, so that the electric reactions could not be taken and the results of treatment be learned.

CHOREA, RHEUMATIC PAINS, AND VALVULAR HEART-DISEASE.

F. L., a school girl, seven years old, presented herself at clinic in the fourth week of an attack of chorea that had developed three weeks after the patient had been abed with what was described as "rheumatic" pain in the extremities and trunk. The movements were for a time so violent that speech was interfered with. The station was firm. There was no ataxia. The knee-jerks were preserved. The pupils reacted to light. There was nocturnal enuresis. The urine was acid in reaction, had a specific gravity of 1008, and contained neither albumin nor sugar.

In the precordia a loud, blowing, systolic murmur was heard, propagated to the axilla and to the angle of the left scapula.

A younger sister of the patient had had an attack of chorea a few months previously, following a fright. A maternal aunt had also had chorea, following a fright.

The following prescription was given, with excellent results, the chorea gradually disappearing:

℞.—Tinct. belladonnæ . . . fʒj.
Liq. potassii arsenitis . . . fʒij.
Syr. hypophosphit. comp. . ad fʒiij.—M.
S.—A teaspoonful to be taken three times a day.

CLINICAL MEMORANDA.

THREE CASES OF NEUROTIC EDEMA FOLLOWING TRAUMATISM.

By ORVILLE HORWITZ, B.S., M.D.,
LECTURER ON GENITO-URINARY DISEASES AND DEMONSTRATOR OF SURGERY IN JEFFERSON MEDICAL COLLEGE, AND SURGEON TO THE PHILADELPHIA HOSPITAL.

THE only papers referring to the subject of neurotic edema that I have been enabled to find are, one read before the Philadelphia Neurological Society by Dr. William Osler, and a report of several cases detailed by Dr. Allen J. Smith, in THE MEDICAL NEWS for March, 1889, under the title of "Angeo-neurotic Edema." The cases reported by these gentlemen were not due to traumatism, and it is, therefore, presumed that those herein referred to may not prove uninteresting.

During the latter part of June of last year a man in the prime of life presented himself at the out-patient surgical department of the Jefferson Medical College

Hospital, giving the following history: Five years previously he had contracted a chancre, which was followed by secondary syphilis, for which he was under treatment for several months. He was apparently perfectly cured, and had no further trouble until the latter part of the preceding January, when a small hard nodule made its appearance under the skin of the penis just back of the right side of the glans. The nodule was somewhat larger than a pea and firmly attached to the deeper structures. There was no pain, and the man paid no attention to the circumstance for four or five weeks, at the end of which time the swelling began to increase. It became indurated, hot, red, and painful. In this condition he applied to a physician, who punctured the part with a needle, and informed him that he was suffering from an abscess, and that he should be operated upon as soon as possible. Not being satisfied with this diagnosis, he applied to a notorious quack, who told him that he was afflicted with cancer, and undertook to cure him by means of a plaster applied to the part. Under this treatment ulceration rapidly supervened, accompanied by swelling, and, as the patient expressed it, the penis began rapidly to "melt away." When he came under my observation I found the organ to be in a state of subacute inflammation, with enlargement and thickening. On the right side there was a large indurated ulcer, with ragged undermined edges; the base was covered with a dirty-white pultaceous slough; the right half of the glans penis was entirely destroyed, and the urethra opened behind the head of the penis. The glands in the groin were not involved. The general condition was fair; the patient was somewhat anemic. The diagnosis of gumma was made, and the patient was placed upon the usual specific treatment, with appropriate attention to the local condition; the ulcer cicatrized. The patient was discharged, in course of some six weeks, cured. During the latter part of last August he again presented himself at the hospital and complained of an inability to pass water. On examination, it was found that the scar resulting from the ulceration had contracted, the urethra closing, so that it was with difficulty located; when found the passage was too much diminished to permit the passage of even a small silver probe. The bladder was very much distended with urine. The urethra was freely opened by means of a curved tenotome, and a No. 26 F. meatus bougie was inserted as far as the peno-scrotal junction. The man was directed to go to the closet and pass his water. In a few moments he returned very much alarmed. He stated that the urine started without any trouble, but his penis began immediately to swell, and the tumefaction soon increased to such a degree that complete phimosis supervened with stoppage of the flow of the urine. The penis was found to be enormously swollen; it was at least three times its natural size, the edema extending over the whole organ, involving the upper portion of the scrotum, and extending to the peno-scrotal junction, where the swelling took the form of a pouch. The skin was very tense and shiny; it did not pit on pressure, and it was absolutely painless.

At first I was puzzled to account for the condition of affairs. I argued that it could not be a rupture of the urethra, with extravasation of the urine, because of the short space of time it had taken for the whole penis and scrotum to become edematous. The patient was perfectly free from pain, which indeed was the most noticeable point. There had been no manipulation of the urethra of any moment, and the canal was unobstructed from the bladder to the orifice of the urethra at the time the swelling took place. I knew that if a rupture of the canal had taken place the percolation would at the outset have been localized. The man had had a long-standing inflammatory lesion of the penis, with syphilitic history; hence I thought there might be a diseased condition of the veins, and that probably the slight manipulation necessary to perform the needed operation might have resulted in a clot in the damaged vessels. Keeping in mind the great rapidity with which swelling had supervened; that there was no pain; no tenderness over the course of the veins, and that there was an absence of engorgement of the superficial veins, I came to the conclusion that the case was one of edema, due to nervous influence.

The skin was slightly punctured with a needle, and the resulting drop of fluid that exuded was found to be perfectly clear. The patient was put to bed and ordered an eighth of a grain of pilocarpine, together with a saline purgative; direction was given to elevate the penis against the abdomen, and an application of lead-water and laudanum was ordered. The next morning the swelling had completely disappeared, and the patient was discharged.

This case is particularly interesting from the fact that it might be repeated in practice at any time, and if not understood might prove a cause of great anxiety to the physician, and be a subject of alarm to the patient. The swelling could not have been due to inflammation, as at the time of the operation the onset of the effusion was almost instantaneous. It could not have been due to embolism, or the patient would not have been convalescent by the following day. There is only left, therefore, the theory of disturbance of the vasomotor system of nerves to account for the phenomena.

The second case is that of an old gentleman whom I found suffering from a small furuncle, about the size of the little-finger-nail, situated on the top of the scalp. I incised it and pressed out a drop of pus, and dressed the wound with a little vaseline. In a very short space of time I received an urgent message to come to the hotel as soon as possible to see my patient, as he was very ill. I found him sitting up in bed with the right side of his face and ear enormously swollen. The affected part did not pit on pressure, and was neither hot nor painful. The temperature was normal; the tongue clean. I ordered a poultice to be applied to the face, and directed a Seidlitz powder to be taken, and in the course of forty-eight hours the swelling had entirely disappeared.

The third case came under my observation at the Philadelphia Hospital. The patient was a man well advanced in years, who had been admitted to the surgical wards, and who was supposed to be suffering from surgical erysipelas. The man had been drinking for a day or two previously to his admission to the hospital. Whilst under the influence of liquor he had fallen in the street and received a very slight superficial wound of the occiput. On the following day, his face began to swell, and he was brought to the hospital. There was

extensive edema of the eyelid and upper lip, but no fever, no pain, and the bowels were regular; the effusion was firm and elastic; the tissues did not pit on pressure. A cathartic was ordered, to be followed by a dose of bromide of potassium at bedtime, and the wound, which was slight, was directed to be dressed antiseptically. By the next evening the effusion had been absorbed.

The diagnosis of neurotic edema is readily made if the practitioner bears in mind its sudden onset, the absence of pain, and that the effusion is unaccompanied by the usual symptoms of inflammation, together with non-pitting on pressure, which is probably due to the fact that the swelling is principally confined to the dermal structure, and not to the sero-cellular tissue, as is the case in edema from inflammatory causes.

In the case first reported the swelling took place long before inflammation could have set in; in the second case, there was a small spot of localized inflammation present, but the effusion did not occur until the slight incision had been made, and then it followed at once; and in the third case the wound was a mere scratch upon the occiput, yet it was followed by extensive swelling of the face.

These cases, together with the reports of Drs. Osler and Smith, would go to show that this form of edema is not so rare as it is generally supposed. I have been consulted by several patients, who have awakened after a night's sleep and found either one or both eyelids swollen without any apparent cause, there being neither heart-disease nor kidney-disease present. The swelling would usually disappear in the course of an hour or so, and the patient being placed on an iron and tonic treatment for a couple of weeks, no further trouble resulted.

The question naturally arises how far the swelling in those parts of the body that have loose connective tissue may be due to nerve disturbances. In operating by the open method on varicocele and hydrocele, in spite of using drainage, I have always found that there has resulted an immense amount of swelling, that is usually hard, elastic, giving rise to no pain, and not pitting on pressure, the patient's temperature being at the same time normal. In many cases the swelling has been so great that were it not for the fact that the subjective symptoms were natural, and that scarcely any discharge presented itself, a looker-on might easily be led to believe that the drainage-tube was blocked, or that it was inefficient. The swelling, however, readily subsides, leaving the inference that the edema is due to nervous disturbance.

No doubt the lymphatic system is somewhat involved in these edematous conditions, but as to this it is impossible to decide positively.

Neumann has demonstrated experimentally that the lymphatic vessels are narrowed by pressure, and that the lymphatic corpuscles are banked up in the canals, and that they thus aid in the general swelling. This would seem to be substantiated by the fact that an examination by the microscope shows the effused fluid to be composed of leukocytes and clear serum. That in some cases there is an angiomatous condition of the lymph-vessels of the corium, due to an altered nerve-supply, would seem highly probable. For this latter variety Dr. Smith suggests the name of acute neurotic lymphangioma.

A FATAL CASE OF LARYNGISMUS STRIDULUS IN AN INFANT SIX DAYS OLD.

BY W. SINCLAIR BOWEN, M.D.,
OF WASHINGTON, D. C.

ON Monday night, July 28, 1891, I was called to see Mrs. H., aged twenty, a primipara, and found her in the first stage of labor; vertex presentation; position, left mento-anterior variety. The first stage lasted twelve hours; the second, one hour; and the third, ten minutes. The infant, a female, breathed well as soon as born, was well formed, weighing fourteen pounds. Chloroform was used during the delivery of the head and shoulders; there was no laceration of the perineum or indeed any accident to mother or infant, the labor being normal in every respect. So soon as the mother was made comfortable, the infant was put to the breast; it seized the nipple, but obtained little else than colostrum, until the end of the second day, when the milk flowed freely, but was of an unusually yellow color for twenty-four hours. For five days all went well; the infant nursed, emptied its bowels and bladder regularly; at the end of this time the umbilical cord had dropped off. On the sixth day, at my usual morning visit, I noticed that the infant did not nurse regularly or with the same ease as it had; it would seize the nipple for only about a minute at a time, its breathing seeming to be interfered with. I instructed the nurse to hold its head in front of a large window, and with the aid of a small spoon as tongue depressor, I was able to secure a fairly good view of the pharynx, but could see nothing abnormal; nor was there anything to be found by external examination of throat and neck; no glandular enlargements whatever were present. A slight rhinitis was the sole abnormal condition to be detected. Up to this time there had been no marked paroxysm of dyspnea. I ordered a powder of gr. $\frac{1}{8}$ potassium chlorate, with gr. j white sugar, to be placed on the tongue every hour, and told the nurse to keep the patient and surroundings as quiet as possible. I then left and returned after an absence of one hour and a half. At my second visit I found that there had been one marked paroxysm, one-half hour previously, and a second occurred soon after I entered the room. From a condition of quiet and natural repose, with easy and regular respiration, there was noticed a catch in the breathing, followed by more spasmodic respiratory movements, the inspiratory act becoming more and more stertorous until finally suspended. There were general tonic convulsions involving nearly all of the muscles of the body and extremities, especially those of respiration, the thorax becoming hard and immovable; the forearms were strongly pronated, the wrists flexed, and the thumbs bent on the palms of the hand; the head was extended and the lower limbs rigid, giving the body the opisthotonus position. The face and neck became livid and covered with large drops of perspiration. During the attack, death seemed imminent, as neither pulse nor respiration could be detected. After a period of about a minute, but seemingly longer, the spasm relaxed, the pulse returned, also the respiratory movements; not, however, with the noise attending inspiration as at the commencement of the paroxysm; the face and neck resumed the natural color, and the little patient seemed as comfortable as ever before, but refused to

nurse. I diagnosticated the case as one of "laryngismus stridulus," and informed the parents of its serious nature. We at once put the infant in a warm bath (96° Fahr.), and I sent for Dr. Richardson, who shortly arrived, and confirmed the diagnosis, as well as the unfavorable prognosis. He advised the use of potassium bromide in gr. j doses, at intervals of half an hour, and this was administered regularly. The paroxysms continued to recur at shorter intervals and with increased severity, and at about twelve that night I began the administration of chloroform by inhalation and prevented any more paroxysms, beginning with the inhalation at the first evidence of an attack, and withholding the anesthetic so soon as relaxation began. During the entire day no nourishment had been taken, and I now began to pour down its throat a little of its mother's milk, freshly drawn, by means of a small spoon. During the four hours following I succeeded in getting it to swallow nearly a glassful of milk, but at the end of this time it died, apparently from exhaustion.

There are two points to be considered in this rather uncommon affection—the paroxysm itself and the underlying general condition giving rise to the spasm. As to the paroxysm itself, I can say that it was very severe, but I do not know what underlying general condition existed to give rise to the spasm.

The infant was large, well proportioned, and gave no evidence of rickets or any other constitutional dyscrasia. The parents are both well developed and healthy. Dr. Morris Lewis, in Keating's *Cyclopedia of Diseases of Children*, says: "When the paroxysm is very pronounced and accompained by carpo-pedal spasm or merges into general convulsions, the prognosis becomes very grave." Reid states that of 289 cases that he collected, 115 died; and Meigs and Pepper state that of 61 cases, 4 died of intercurrent or consecutive diseases, while of the remaining 57, 32 were cured, and 25 (or about 48 per cent.) died of the malady itself; adding these cases together makes a total of 350, with 140 deaths, a percentage of 40. A disease attended by so great a mortality demands the most careful study and investigation. Treatment in the case just cited proved futile, and a point of great interest I think is in regard to the early use of chloroform by inhalation to mitigate the severity of the paroxysms and prevent their recurrence, rather than admit delay by the use of less speedy and less efficient agents when the symptoms are severe almost from the very outset of the disease.

In other forms of convulsions chloroform is used with most happy results, and by the profession at large it is considered to be "the sheet-anchor" in puerperal convulsions. In infantile convulsions Henoch considers any other initiative treatment a waste of time.

In looking up the literature of the subject I have found no similar case fatal in an infant so young.

TWO CASES OF XERODERMA PIGMENTOSUM.

By GEORGE MURPHY, M.D.,
OF LEO, INDIANA.

Having observed in Taylor's *Atlas* that but forty-one cases of xeroderma pigmentosum had been reported up to the time of the publication of that work, it seemed to me that a report of two well-marked cases in one family would prove interesting. The parents of the patients were healthy; the father was a farmer. There was no family history of cutaneous affection; nor were the remaining five children affected.

The elder of the patients was a boy a little more than ten years old. At the age of three months it is said that he had a fever, lasting a week, and immediately followed by an eruption of minute vesicles; these were replaced by small areas of pigmentation. In the third year the skin was observed to be hypertrophied in patches, and, subsequently, small tumors, about the size of squirrel-shot, appeared. During the eighth year dark-bluish tumors developed, attaining diameters of from half an inch to an inch and a half; these were somewhat pendulous, resembling large warts; they disappeared by sloughing, or by violence while the child was playing. As the growths disappeared they were replaced by others; and these, in turn, disappeared, until finally there had been at least twelve. The general health of the patient was preserved. About two years ago a slight pannus of the right cornea was observed. At this time the lower lid of the right eye began to be eroded. About a year ago an opacity of the left cornea appeared. Pigmentation was but recently observed upon the arms and forearms. A tumor about three quarters of an inch in length appeared upon the posterior aspect of the integument of the right helix, separating spontaneously about a year ago. In this situation there is a depression of the integument, and the cartilage at its anterior aspect is somewhat thinned. A small scaly mass developed on the left helix. At present vision in the right eye is lost; the outer half of the cornea and adjacent sclerotic are thinned and staphylomatous, evidently as the result of a previous growth in this situation. The lower right eyelid has been completely destroyed by erosion; its margin is not indurated. There is slight pannus of the inner and upper three-fourths of the left cornea, as well as a small, white growth, about one-fourth of an inch long and about two lines in breadth, upon the external inferior quadrant of the left cornea. The left lower eyelid, with the exception of one-fourth of an inch at the outer extremity, is destroyed. There is suppurative conjunctivitis of both upper eyelids. There is a tumor, three-fourths of an inch in length, situated over the body of the right malar bone; it evidently does not extend beneath the integument. This tumor is somewhat pendulous, is black, and sloughing at the summit. Last week it was one and one-fourth inches in length, but has sloughed off so as to be one-half of an inch less in length at present; it has a circular base.

There is one tumor near the left extremity of the lower lip: about one-fourth of the base of the tumor involves the mucous membrane; the other three-fourths involves the integument of the lower lip. The tumor is one-half of an inch in diameter, circular, and the base slightly narrower than the summit. There is another, of a reddish color, about a sixth of an inch to the right of that last described; it is situated wholly upon the mucous membrane of the lower lip. The tumor on the cheek made its appearance six months ago; the larger one, upon the lower lip, three months ago, and the smaller one a week ago. The greater portion of the integument of the face is shining and atrophied. The portion of the skin of the face not atrophied presents numerous telan-

giectases; the forehead, a large number of the black pigmentoses; and the skin over the entire body is harsh, from apparently unhealthy epithelium. The integument of the superior and inferior extremities is covered by black pigmentoses. The neck and upper part of the chest presents an intermingling of black, brown, and red spots.

The second case is that of a girl, six years old, in whom the disease appeared at the age of three or four months. As in the first case, the onset was preceded by fever. Within two weeks pigmentoses appeared. Some of the patches are now brown, others black. They are present in great abundance on the face, forehead, and outer aspect of the forearms, as well as on the dorsal aspect of the hands. The general health of the child is good. There is slight conjunctivitis of the lower eyelids, as well as hyperemia of the ocular conjunctiva; but none of the small tumors usually described as belonging to the less advanced period of the disease.

A FETAL MONSTROSITY.

BY J. J. CANON, M.D.,
OF MOSCOW, TEXAS.

ON February 3d, I was called to see a primigravid negress, twenty-two years old, who was resting well, with pulse and temperature normal; the bowels were constipated. On inspection I found the abdomen large and tense, presenting a tumefaction with its long axis transverse. On palpation I was able to detect the head of a fetus on the left side. There were no signs of fetal

life. I gave the patient fluid extract of senna to move the bowels. On the following day the os uteri was well dilated, with the breech of the child presenting. A foot was brought down and the labor was completed without any trouble. In grasping the child in delivery the skin peeled off in several places. The mother believed that the child had been dead about forty-eight hours.

The fetus had only a rudimentary brain; one anterior nasal orifice; hare-lip; cleft palate; the superior maxillary bone being in two distinct pieces.

The feet and hands were extremely large, the fingers unusually long; the body was covered with a fine hair. The head was almost flat, the distance from the glabella anteriorly to a corresponding point posteriorly being but one and a quarter inches.

MEDICAL PROGRESS.

Para-peritoneal Nephrectomy for Tuberculosis of the Kidney.—RIVIÈRE (*Lyon Médical*, 1892, No. 9, p. 288) has reported the case of a woman, twenty-five years old, who for fifteen months had complained of pain in, and increased frequency of, micturition. In the course of a year, paroxysms of pain in the right loin, lasting for four or five hours, occurred. The urine, on standing, deposited a dense sediment containing pus and minute calculi. The pain subsequently became constant and associated with a sensation of burning. A tumor, painful on palpation, then became apparent in the right loin. Pollakiuria was decided. The temperature rose to 104° and was uninfluenced by antipyretics. The general condition failed. The tumor in the loin was separable from the liver. On palpation, it yielded a sense of elasticity, without fluctuation. On vaginal examination, the anterior wall of the bladder was found to be thickened, indurated and painful; in the right lateral cul-de-sac a painful longitudinal tumor could be felt in the course of the ureter. In the absence of evidence of tuberculous infection, a diagnosis of calculous pyelo-nephritis was made and nephrotomy determined upon. A vertical incision was made between the twelfth rib and the crest of the ilium, outside of the latissimus dorsi muscle. The peritoneum was pushed forward. The kidney when exposed presented many tubercles and granulations. It was decided to remove the organ, and its pedicle was ligated *en masse*, and severed without difficulty and without hemorrhage. The kidney was caseous and excavated, but contained no calculi.

The Action of Soluble Ferments upon the Diphtheritic Poison.—To determine the nature of the diphtheritic poison, GAMALEIA (*Compt. rend. hebdom. des Séances de la Soc. de Biol.*, 1892, No. 7, p. 153) exposed the filtered products of cultures of bacilli of diphtheria to the action of various ferments, and found that of maltin, invertin, emulsin, pepsin, and trypsin only the last two modified the toxicity of the cultures. Pepsin was active only in an acid medium. Doses of the filtered products, otherwise immediately fatal, could, after peptonization, be injected into guinea-pigs without at once causing death. A cachexia, however, was induced that ultimately proved fatal. The explanation is that the diphtheritic poison is an albuminoid substance from which pepsin separates a nucleo-albumin, likewise possessing toxic properties and provocative of a cachectic condition.

It is assumed that the diphtheritic poison does not cause toxic symptoms when introduced into the intestinal canal because the nucleo-albumins are decomposed and the nucleins are not absorbed. It is also believed that the destruction of the diphtheritic poison in the

bodies of refractory animals is not analogous to proteolytic digestion, for this does not destroy the toxicity of the nucleins, the presence of which would give rise to fatal cachexia.

The Blood in Acute Rheumatism.—At a meeting of the Royal Medical and Chirurgical Society of London, Garrod (*British Medical Journal*, No. 1624, p. 335) reported the results of a study of the blood in acute rheumatism, based upon some eighty examinations. It was found that an attack of rheumatism was always attended with a considerable diminution in the number of red corpuscles, the diminution setting in early. When convalescence took place the number was restored to the normal. There appeared to be no connection between the variation in the number of red corpuscles and the temperature-curve. The variation constituted a more delicate index of the activity of the rheumatic process than did the temperature-chart. The changes in the percentage of hemoglobin corresponded pretty closely to those in the number of corpuscles. Exceptionally the relative percentage of hemoglobin was lower than the absolute percentage. No relation was found to exist between the condition of the blood and the presence of urohematoporphyrin in the urine. The anemia of rheumatism thus appears in two forms: an acute oligocythemia, which is rapidly recovered from and requires no special treatment, and a more chronic condition of pseudo-chlorosis, which may outlast the attack, and in combatting which iron is therapeutically of great value.

The Part Played by the Spleen in Artificial Immunity to Tetanus.—Tizzoni and Cattani (*Centralbl. f. Bakteriol. u. Parasitenk.*, 1892, No. 11, p. 325) have sought to determine whether the immunity-conferring substance found in the serum of animals inoculated with the products of bacterial activity is introduced from without, or is developed within the organism of the animal, from the irritation of the toxic products; and in case of the latter, whether the property is possessed by all of the elements of the body, or by only certain of them. They inoculated with culture-products of bacilli of tetanus a number of rabbits, at intervals of from fifteen to forty-five days after successful removal of the spleen, as well as a number of control-animals. Under otherwise like conditions, while all of the second group of animals survived, those of the first died within the same time and amid the manifestations presented by animals that were not protected.

Toxicity of the Blood in Mammifera after Removal of the Supra-renal Capsules.—Abelous and Langlois (*Compt. rend. hebdom. des Séances de la Soc. de Biol.*, 1892, No. 7, p. 165) have found that in frogs removal of both supra-renal capsules is followed by paralysis and death. Injection of the blood of the dying animals into other frogs is likewise followed by progressive paralysis. In both cases the irritability of the nerves is soon lost, while that of the muscles remain. In guinea-pigs, removal of one supra-renal capsule is not followed by death, while removal of both is followed by death, preceded by paralysis beginning in posterior extremities. Sensibility is apparently preserved. That the paralysis is dependent upon an influence upon the peripheral filaments of the motor nerves is demonstrated by the fact that the paralysis did not take place in a part of which the circulation was controlled by ligature while the nerve-supply was left undisturbed.

A Case of Combined Paralysis Agitans and Posterior Spinal Sclerosis.—At a meeting of the Berlin Society for Psychiatry and Nervous Diseases, Placzer (*Centralbl. für Nervenheilk. u. Psychiatrie*, February, 1892, p. 5) presented a man, fifty-two years old, who had a history of syphilis of thirty years' standing. At forty-two he had lightning-pains and looseness of the teeth; and potence diminished. Soon, the tremor of paralysis agitans appeared and the face became immobile and expressionless. The pupils were small and irresponsive to light; the knee-jerks were abolished; station was unsteady; the functions of the bladder were deranged. There was some diminution of the pain-sense in the right lower extremity. Memory was enfeebled.

Cholecystocolotomy.—Chavasse (*Lancet*, No. 3576, p. 568) has reported the case of a man, forty-eight years old, in whom cholecystotomy for the relief of jaundice, dependent upon biliary obstruction by calculi, was followed by the persistence of a biliary fistula. Other measures failing, with the aid of bone-plates, a communication was established between the gall-bladder and the colon at its hepatic flexure. At first bile and fecal matter were discharged through the abdominal wound, but ultimately this closed, the stools were passed naturally, and the general condition of the patient was much improved.

Radical Treatment of Hernia.—In a paper read before the Philadelphia County Medical Society, Shimwell expressed the view that in a number of cases the occurrence of hernia is primarily dependent upon excessive length of the mesentery. In these cases he proposes to accomplish a radical cure by shortening the mesentery. He believes that the operation is unattended with grave danger. He would effect the shortening by folding the mesentery on itself, holding it thus by interrupted sutures.

The Differentiation of Pseudo-leukemia and Glandular Tuberculosis.—Weishaupt records an interesting observation in which tuberculosis of the lymphatic glands simulated pseudo-leukemia. A man, twenty-one years old, who applied for treatment in an attack of influenza, had for thirteen years presented glandular enlargement. One of the glands had softened, and a fistula had formed. The urine was albuminous; the spleen and liver were enlarged. Symptoms of bronchitis were present, and there was febrile movement. Tubercle-bacilli were sought for, but not detected. Death took place, and lymphomata were found in the neck and abdomen; small lymphoid nodules in the lungs, kidneys, and liver. The evidences of bronchitis and catarrhal pneumonia were present, as well as ulceration of the bowel. Based upon the macroscopic examination, a diagnosis of pseudo-leukemia was made. Microscopically, however, it was demonstrated that the lymph-glands were in a condition of hyaline necrosis, and contained tubercle-bacilli. Tubercle-bacilli were also found in the margins of the intestinal ulcers, but not in the lungs, kidneys, or liver.—*Centralbl. f. klin. Medicin*, 1892, No. 10, p. 193.

THERAPEUTIC NOTES.

Tumenol in Dermatologic Practice.—Tumenol is the name given to a preparation recommended by NEISSER (*Deutsche medicin. Wochenschr.*, 1891, No. 45) as an efficacious remedy for some forms of eczema and for the relief of itching. Like ichthyol, tumenol is prepared from the bituminous layers of earth. While the basis of ichthyol is a substance containing a large proportion of sulphur, that of tumenol consists of unsaturated carbohydrates having a strong affinity for oxygen and acting as reducing agents. Tumenol is obtained from these carbohydrates by the action of concentrated, fuming sulphuric acid. Tumenol is not an elementary body, but a mixture of tumenol-sulphone, or tumenol oil, and tumenol-sulphonic acid, or tumenol powder. Tumenol is with difficulty soluble in water, but makes a clear solution with a mixture of alcohol, ether, water, and glycerin. Tumenol has been employed as an ointment (from 5 to 10 per cent.); tumenol oil has been used pure or as an ointment; tumenol-sulphonic acid has been used as a powder or in a 5 per cent. solution in water. Tumenol is of black color; it leaves no permanent stains upon linen; it has a faint, inoffensive odor; it has no antiparasitic activity; it is non-toxic to animals; it is but slightly irritant. The therapeutic applications of tumenol are: 1, as a drying, antiphlogistic agent, facilitating cicatrization, especially in moist eczemas, erosions, excoriations, superficial ulceration; 2, to relieve itching, not only in parasitic dermatitides and in eczema, but also in forms of prurigo and pruritus.—*Berliner klin. Wochenschr.*, 1891, No. 10, p. 235.

Thymacetin.—At a meeting of the Berlin Society for Psychiatry and Nervous Diseases, JOLLY (*Centralbl. für Nervenheilk. u. Psychiatrie*, February, 1892, p. 50) reported results obtained from the employment of thymacetin (a white, crystalline powder, insoluble in water) in doses of from four to fifteen grains, in thirty cases of headache of varied kind. True hemicrania was scarcely influenced; considerable relief was afforded in one case, but unpleasant secondary manifestations occurred. In a number of cases of habitual diffuse headache or transitory headache, the pain was usually mitigated. In cases of headache of organic cerebral origin the remedy was without effect. It proved serviceable in cases of neuralgic headache. The result was variable and uncertain in cases of morphinism. Thymacetin acted much like phenacetin. It may cause a sense of fulness and throbbing in the head; the pulse may be retarded; drowsiness may be induced. In sixteen of twenty-six cases a dose of seven and a half grains acted as a hypnotic.

Toxic Symptoms from Sulphonal.—KOBER (*Centralbl. für klin. Medicin*, 1892, No. 10, p. 185) reports the case of a woman, fifty-two years old, with a tendency to melancholia, who suffered from marked insomnia, for which sulphonal was prescribed in doses of from seven to twenty-two grains daily. Some amelioration of the symptoms followed, but nausea, vomiting, abdominal pain, constipation, increased thirst, and apathy developed; while the urine, which assumed a Burgundy-red color, was eliminated at infrequent intervals in diminished quantity. The urine at first contained no albumin and no formed elements, and at no time sugar, but subsequently albumin and casts of various kinds appeared. Investigation disclosed the fact that the discoloration was due to the presence of hemoglobin. Red corpuscles were not found, nor could sulphonal be detected in the urine. Despite the withdrawal of the drug, the symptoms persisted and the patient died of heart-failure.

Morphine in Heart disease.—HERVOUET (*Revue gén. de Clin. et de Thérap.*, 1892, No. 4) maintains that passive hyperemia is not a contra-indication for the employment of morphine or opium in cases of disease of the heart. With the venous congestion is usually associated arterial anemia. By removing dyspnea and nervous manifestations morphine may succeed when other remedies have failed. In some instances, morphine acts not only as a calmative, but also as a stimulant, increasing the powers of the patient and fortifying the action of other medicaments. The presence of albumin in the urine is not a contra-indication for the employment of morphine when the albuminuria is dependent upon the disease of the heart. It has been demonstrated that morphine may also with advantage be injected subcutaneously in the uremia of chronic nephritis.—*Centralbl. f. die ges. Therapie*, 1892, x, 3.

The Treatment of Posterior Spinal Sclerosis by Extension.—BENEDIKT (*Wiener medizin. Presse*, 1892, No. 1, p. 4) reports the employment of extension of the vertebral column in a considerable number of cases of posterior spinal sclerosis, with most happy improvement in gait and station, and with mitigation of the neuralgic pains. He employed a modification of a method originally described by Bonuzzi, in which no apparatus is required. The patient is made to lie supinely on a table, bed, or sofa, with the head and upper portion of the spinal column partially elevated, while the lower extremities are grasped at the ankles and carried upward over the body and brought down over the shoulders. In this way it has been demonstrated, a considerable degree of extension of the spinal column is obtained. The method possesses manifest advantages over suspension.

Antiseptic Diuresis.—The following formula is recommended in infectious nephritis for its diuretic and antiseptic effects:

℞.—Sodii benzoatis . . . ʒiv.
Aceti scillæ } . āā f ʒjss—M.
Syrup. aurantii cort. }

S.—A teaspoonful every hour or two, according to age.—*Rev. de Thérap. Méd.-chir.*, Nov. 5, 1892.

For Cardialgia.—In some cases of cardialgia in hysterical and neurasthenic subjects, good results have been obtained by the employment of tincture of piscidia erythrina, in doses of twenty drops, given daily.—*Deutsche med. Wochenschr.*, 1892, No. 7.

Creasote for Influenza.—ISELIN (*Corr.-bl. f. Schw. Aerzte*) recommends creasote in doses of from fifteen to seventy-five minims daily in the treatment of influenza.—*Deutsche med. Wochenschr.*, 1892, No. 7.

The Medical News.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to The Medical News will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,
1004 Walnut Street,
Philadelphia.

Subscription Price, Including Postage in North America.

Per Annum, in Advance . . . . . $4.00.
Single Copies . . . . . 10 cents.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
Nos. 706 & 708 Sansom Street,
Philadelphia.

SATURDAY, APRIL 16, 1892.

CONSULTATION WITH SECTARIANS AND QUACKS.

We are in receipt of a letter, asking advice upon the subject expressed in the caption of this article. Our correspondent says:

"There is a man here who tried to graduate from the University of Pennsylvania, but failed three times. He then attended some homeopathic college, and graduated. He prescribes for or treats patients according to whichever school they wish. As a young physician, I am advised to keep clear of him, yet Dr. ——, an elder graduate, meets him, particularly when there is a $10 bill waiting. Dr. —— is a member of —— County Medical Society, and if it is right for him, why not for me, who need a $10 fee more than my older brother? Yet I have refused three consultations, or $30, for fear that I would be violating that code held so sacred by physicians. Sometimes good physicians blunder on these so-called quacks, meet at the bedside, discuss the case privately, advise as to future treatment, collect $10, but *say* that no consultation has been held. What is right? What is wrong? Tell me that I may know if I am justified in foregoing the money I, as a struggling young man, so much need."

Before replying to the quoted portion of this letter, we desire, in passing, to deprecate the use of the terms "regular" and "irregular" practitioners, elsewhere employed by our correspondent.

There are but three possible divisions of medical practitioners—physicians, sectarians, and quacks. The physician is catholic, the sectarian is exclusive, and the quack is commercial. The true physician and the true sectarian may be both honest. The quack may be scientifically educated or grossly ignorant; he may belong to the so-called "regular profession," to one or all of the "irregular" sects, or be openly an Ishmaelite. His actions, not his pretences, determine his standing.

The question put by our correspondent was discussed at length at a meeting of the Philadelphia County Medical Society, and two papers taking opposite views of the question were published in The Medical News for October 18, 1889. To them we would refer our correspondent for a more detailed consideration of the theme than our present space will permit.

One of the authors contended that, while it is the duty of members of the American Medical Association to obey the code, which at present forbids consultation with those professing to base their practice on therapeutic dogmas, to the exclusion of accumulated experience, and the aid of the sciences collateral to medicine, yet that the construction of that prohibition as against educated homeopathic practitioners was unwise and unjust. He claimed that at the Hahnemann Medical College, of Philadelphia, the text-books and methods of instruction were the same as those employed at the University of Pennsylvania and at Jefferson Medical College—that the graduates of Hahnemann College were therefore thoroughly educated physicians, and hence one might properly meet them upon an equal footing at the bedside. In reply, it was argued that homeopathy, if it meant anything at all, meant exclusive treatment on the principle of *similia similibus curantur;* that hence there was no possible common ground upon which those who consistently believed in and practised homeopathy (honorable sectarians), could meet physicians, in consultation, and that consultation, being thus doomed from the first to be fruitless, was manifestly immoral. It was further urged, that if, on the other hand, the person calling himself a "homeopath" did not honestly believe in the doctrines and carry out the practice of his sect, he was a not-honorable impostor, and that while agreement as to treatment might be possible, yet to meet such a one in consultation would be to

condone his duplicity and thus partake in his dishonor. The almost unanimous voice of the Society was with the latter speaker.

Persons of the kind alluded to by our correspondent, who profess to practise according to either "old school" methods or "new school" methods, as their patrons may wish, are so manifestly incompetent, insincere, and commercial, that we fail to understand how the thought of meeting them in consultation can for one moment enter the mind of any honorable physician. The man whose honor can be purchased for $10 or for $10,000 is unfit for membership in any decent society, medical or non-medical.

It has been well said by a leading jurist of this city: "He that studies the provisions of the law that he may do everything not punishable, has our just contempt." In line with this thought is the position of THE MEDICAL NEWS, that consultations with quacks, and other acts forbidden by the code of the American Medical Association, are not to be avoided merely because they are thus forbidden, but because such acts are wrong in themselves, and will continue to be wrong, even though the efforts of the mercenary and the misguided should succeed in effecting the formal repeal of the prohibitory statutes. We congratulate our correspondent upon his firmness in refusing to follow the bad example of Dr. ——.

The question herein considered is one of simple honesty. It has nothing to do with the correctness or incorrectness of the "homeopathic," "naturopathic," "rectopathic," "hydropathic," "psychopathic," or any other "pathic" dogmas. We recognize that applied therapeutics is an art, not an exact science, and that men have a right to differ in opinion and in method.

If those graduates of the Hahnemann or any other sectarian college, who have abandoned Hahnemannian practice—and only such ask for consultation with physicians—would publicly renounce their previous contentions in favor of the exclusive truth of the so-called "law of similars," drop the name of "homeopath," and submit to examination by a properly constituted committee of any State or county medical society, we would not oppose their admission to that society, and their full and free recognition as physicians. So long, however, as the commercial value of the name "homeopathy"—and such a value it undoubtedly has, in common with mesmerism, faith-cure, "professional" and "non-professional" patent medicines, and other impostures—so long as the trade-mark value of the name "homeopathy" prevents these men from adopting the open and manly course indicated, we do not see how self-respecting physicians can consent to professional association with self-confessed medical tradesmen.

OCULAR INJURY IN FORCEPS-DELIVERIES.

UNDOUBTEDLY the difficulties encountered in the delivery of the fetal head by the aid of forceps may excuse the somewhat frequent injuries inflicted in the performance of this delicate operation, but it may also be said that obstetricians may too often have ignored the severe injury to the eyes that may be caused by malposition of the blades of the instrument. These traumata may serve to make one more slow to apply the forceps, and also more careful when their application is ultimately required by the exigencies of the case. The few cases that have been reported serve to suggest many that are not reported, and yet taken together there may be gathered quite a large number on record. Several cases of luxation of the globe are mentioned by ZANDER and GEISSLER (*Die Verletz. d. A.*, 1864), and one by BULLER (*Canada Med. Record*, 1887). BERGER (*Arch. f. Aug.* xvii, 1887) reports a case of paralysis of the levator palpebræ and superior rectus, with ptosis.

PAUL BLOCH (*Centralbl. f. prak. Augenheilk.*, May, 1891) enumerates 438 cases of paralysis of the abducens in 116,000 patients who visited PROF. HIRSCHBERG'S eye clinic from 1869–90. Of these, 31 were congenital, and 3 of these originated during birth from the use of the forceps. He has compiled the literature of the subject of forceps-injuries as follows: ZWEIFEL (*Lehrbuch der Geburtshülfe*) attributes traumatic exophthalmos to compression of the cranial bones, and states that eye-lesions are known to be produced by introduction of the forceps. OLSHAUSEN (*Volkmann's Vortr.*, 1870, i, 8) describes creases over the eye as due to the use of forceps. PAJOT (Thèse, Paris, 1853) mentions slight ecchymoses, particularly on the upper eyelids, in difficult births and where the forceps was used, which DUBOIS considered due to compression, and which occasionally furnished the starting-point for inflammation of the lids. BOUCHUT (*Traité des Maladies des Nouveau-nés*, 1862) observed fracture of the frontal bone, with complete exophthalmos, following the use of the forceps. FEHLING (*Peter Müller's Handb. der Geburtshülfe*) mentions the

presence of marked edema of the eyelids and temporary ptosis following the application of the forceps. Kustner (*Peter Müller's Handb. der Geburtsh.*, 1889) gives a very detailed report of injuries of the orbital region in births in which the forceps was used. Schroeder mentions among the injuries due to forceps, fractures of the bones of the roof of the orbit, with exudations into the cerebrum. Lomer found in twenty-seven cranial fractures due to the use of the forceps, ten fractures of the frontal bone in which the pars orbitalis was implicated four times. He also reports a case delivered by Schroeder in which there was exudation of blood into the anterior chamber of right eye, with slight exophthalmos. Hofmann (*Monatsschrift f. Geburtskunde*, 1854) reports two cases of exophthalmos in children of the same woman. In one instance there was fracture with deep depression of the roof of the right orbit and wing of the sphenoid, together with fissure of the roof of the orbit on the left side. Other cases of similar injuries are reported by Nadaud (*Les Paralysies Obstétricales des Nouveaunés*), Coccius (*Programm einer Gedenk. f. G. Rose*, Leipzig, 1870), Steinheim (*Deutsche med. Wochenschr.*, 1883, No. 17) and others.

TUBERCULOCIDIN—A REMEDY FOR TUBERCULOSIS.

When, more than a year ago, the announcement was made that a remedy for tuberculosis had been discovered, the entire civilized world was carried away by the enthusiasm of the moment. It required the bitter lesson of experience to demonstrate that a remedy so potent for good as tuberculin was believed to be, was also capable of incalculable mischief. The reaction was so decided, the disappointment so keen, that complacent faith gave way to extreme skepticism; and to day reports of wonderful results in the treatment of tuberculosis are viewed with querulousness, if not with suspicion. Earnest investigators have, however, devoted themselves to the problem, and it seems as if the promise of the first announcement would yet be realized. In the *Deutsche medicinische Wochenschrift*, 1891, No. 45, p. 1233, Klebs reported that by precipitation with platinum chloride and the so-called alkaloid reagents he was able to separate from tuberculin the substances upon which the deleterious effects of tuberculin depended, leaving in solution an albumose, which he believed to be the curative agent, and to which he has given the name *alexin* or *tuberculocidin*. Experiments upon animals showed that tuberculocidin fails to exercise the depressing influence upon the circulation that tuberculin does, and that, unless the dose be excessive, there is no febrile reaction. On the contrary, the treatment causes a dissipation of hectic fever.

Klebs (*Die Behandlung der Tuberculose mit Tuberculocidin*, Hamburg and Leipzig, 1892) believes that the efficacy of tuberculocidin depends upon an influence exerted on the tubercle-bacilli, resulting in their degeneration. Thus, large doses, by causing rapid disintegration of tubercle-bacilli, cause some elevation of temperature by a form of autoinoculation with tuberculin. Tuberculocidin does not cause necrosis of tuberculosus tissue, with dissemination of bacilli, and the development of a miliary tuberculosis. The process appears to be one of involution, associated with exudation. That tuberculocidin is not merely an attenuated form of tuberculin is demonstrated by the fact that, although the former represents by weight one-fortieth of the latter, an injection of a decigram (0.1) of the one is followed by no elevation of temperature, while an injection of two and a half milligrams (0.0025) of the other is followed by febrile reaction. In man the initial dose of tuberculocidin is about two milligrams (0.002); if this occasion no unpleasant manifestations, the dose is rapidly increased to a decigram (0.1), or a decigram and a half (0 15). Hectic fever constitutes no counter-indication; energetic treatment may cause its disappearance. The injections should be made daily for a month, and then be intermitted for a month, to be resumed or not, according to the indications present. When indicated, other therapeutic measures may be advantageously employed in conjunction with the injections. Nearly a hundred cases, principally of pulmonary tuberculosis, have been treated with tuberculocidin. Of seventy-five in which a reasonable time had elapsed, fourteen were cured; forty-five were improved; fourteen remained unimproved; and two died. Complications were universally wanting.

The results reported are most encouraging. We have learned not to be over-sanguine, and we shall await with much interest the outcome of the investigations now in progress that promise so much in the treatment of a disease the curability of which we have only recently learned to appreciate.

REVIEWS.

THE PRACTICE AND PRINCIPLES OF MEDICINE. DESIGNED FOR THE USE OF PRACTITIONERS AND STUDENTS OF MEDICINE. By WILLIAM OSLER, M.D., Fellow of the Royal College of Physicians, London; Professor of Medicine in the Johns Hopkins University, and Physician-in-Chief to the Johns Hopkins Hospital, Baltimore, etc. Large 8vo, pp. xviii, 1078. New York: D. Appleton & Co., 1892.

BY reason of extensive clinical, pathologic, and teaching experience, of exceptional opportunity and broad training, and of rare scientific attainments, there are few men better qualified than Dr. Osler to write a work on the Practice of Medicine. Here in Philadelphia, where Dr. Osler spent but too few busy years, he will not soon be forgotten; the impress of his work and character will long remain, and the impetus given to careful pathologic study and observation will be transmitted through his colleagues, his assistants, and his pupils. To say that Dr. Osler has performed his task well, is but to echo the verdict concerning the work he has done in the past. If there were one fault of which we would complain, it is expressed in the wish that he had said more than he has. Everywhere throughout the work one feels the delightful personality of the man. Every page contains evidences of original observation and is marked by an enlightened conservatism.

It would be difficult to select any one section and say that it is much better than the others. All are conspicuous for their comprehensiveness. The descriptions are in places concise, but there are no important omissions.

The chapter on Tuberculosis, which, in accord with modern conceptions, is placed among the infectious diseases, is particularly full and brought up to date. The subject is considered under the subdivisions: (*a*) acute (general, miliary) tuberculosis; (*b*) tuberculosis of the lymph-glands ("scrofula"); (*c*) pulmonary tuberculosis: (1) tuberculo-pneumonic phthisis (acute phthisis), (2) chronic ulcerative phthisis, (3) fibroid phthisis; (*d*) tuberculosis of the serous membranes; (*e*) tuberculosis of the alimentary canal; (*f*) tuberculosis of the liver; (*g*) tuberculosis of the brain and spinal cord; (*h*) tuberculosis of the genito-urinary apparatus. In a classification otherwise so complete it might have been well to have included also tuberculosis of the bones and joints, and tuberculosis of the skin. We think, too, the word phthisis might well have been permitted to drop into the obscurity out of which it originated, as the name but perpetuates a false or inadequate pathologic conception.

The article on Syphilis is a praiseworthy one. There seems, however, to be some inconsistency in the statements that "clinically, pulmonary syphilis is not of much importance, as the cases can rarely be diagnosticated," and that "the diagnosis of syphilis of the liver is very important, since upon it the proper treatment depends." The second dictum is the correct one and applies equally to all organs.

In the definition of pneumonia it is said that "an organism—the *diplococcus pneumoniæ*—is invariably found in the diseased lung." The statement is too sweeping, and liable to give rise to misapprehension, as at least one other organism seems to be the etiologic factor in a not inconsiderable proportion of cases.

We think, too, the word carcinoma had better have been substituted for cancer. Cancer has been and is yet occasionally employed to designate malignant neoplastic disease, including carcinoma and sarcoma especially. A proper use of the specific designation will in every case tend to prevent possible confusion.

There seems to have been a difference between the author and the proof-reader as to the correct spelling of the word characterize.

Dr. Osler's work needs no special laudation. It speaks for itself. We most heartily commend his *Practice of Medicine* to those who desire to be in possession of the most recent and best knowledge on the subject with which it has to deal.

DISEASES OF THE THROAT, NOSE, AND EAR. A CLINICAL MANUAL FOR STUDENTS AND PRACTITIONERS. By P. McBRIDE, M.D., F.R.C.P. Edin. With colored illustrations from original drawings. Philadelphia: P. Blakiston, Son & Co., 1892.

THIS book, as the author states in the preface, is designed for the student and general practitioner rather than for the specialist. The student will find it a most excellent manual, but for the general practitioner, with his multifarious duties, it is altogether too technical and voluminous. Owing to the great difficulty in examination of the parts, the majority of diseases of the throat, nose, and ear, cannot be diagnosticated, to say nothing of treatment, by any but those specially trained in manipulative skill and use of instruments. The book, therefore, will appeal particularly to those engaged in this special work, and to such it will be almost invaluable. In a clear, direct manner are presented the results of the experience of some of the best teachers in two countries. While it may be argued that there is little in the book that is new, it must be acknowledged also that there is little that is not good.

Divided into four sections, the work treats of diseases of the pharynx, of the larynx, of the nose, and of the ear.

A regular systematic course is followed throughout each section. We are struck by the small list of remedies recommended. Peroxide of hydrogen and ichthyol, so valuable in atrophic rhinitis, are omitted entirely in this connection, although the former is mentioned as a possible remedy in chronic suppuration of the middle ear.

The section on diseases of the pharynx is specially interesting and generally valuable, because, of all the parts, the pharynx is the most accessible. Like those who have preceded him, however, the author has not done justice to the tonsil, which is responsible for so much trouble in this region. He says nothing of the peculiar adhesions of the pillars of the fauces, and the muco-muscular bands or capsules that often surround and envelop the tonsil, blocking up secretions and causing inflammation of adjacent parts.

In the diagnosis and treatment of laryngeal tuberculosis, Koch's tuberculin is mentioned, but no positive opinion is given as to its value.

In the last instructive section, on diseases of the

ear, several operative procedures, such as opening the mastoid cells and antrum, are clearly and accurately described; but the operation, for which some of our American aurists hope and claim so much, namely, removal of membrane and ossicles for deafness and chronic suppuration, is only referred to as a somewhat doubtful experiment. The work is extremely conservative throughout, and surgical interference is recommended only when less radical measures are sure to fail.

On the whole, there is little in the book that we would have different. The expression "*rude* health" for good health, is a criticisable colloquialism.

A Practical Manual of Diseases of the Skin. By George H. Rohé, M.D., Professor of Materia Medica, Therapeutics, and Hygiene, and formerly Professor of Dermatology in the College of Physicians and Surgeons, Baltimore, etc. Assisted by J. Williams Lord, A.B., M.D., Lecturer on Dermatology and Bandaging in the College of Physicians and Surgeons; Assistant Physician to the Skin Department in the Dispensary of Johns Hopkins Hospital. 12mo, 303 pages. Philadelphia: The F. A. Davis Co., 1892.

Our knowledge of diseases of the skin has increased so largely during the past ten or fifteen years that it is no longer possible for an author to give a complete *résumé* of dermatology in the space occupied by a handbook. An abstract may, of course, be prepared in the compass of such a book, but the information contained in such works is not sufficient for the needs of the practitioner. In the book before us matters are left out concerning which physicians, we think, would like to be informed—such, for example, as the newer modes of applying remedies, as with plasters, salve-muslins, and pastes of different kinds. The views expressed, on the whole, are such as govern the teachings of the majority of American dermatologists, although we note statements that must needs stand correction, such as that lichen scrofulosus "has not been observed in the United States."

The treatment of leprosy is dismissed with literally a half-dozen lines, being altogether insufficient for so important a subject. The chapter devoted to the cutaneous manifestations of syphilis is the longest and the best. Authors are quoted here and there, but, as a rule, without the references being given. The pathology and etiology of the several diseases are hardly up to date, the mention of the influence of microörganisms, as in furuncle and sycosis, being omitted. Psorospermosis, which has excited so much interest and discussion of late, is not referred to. Urticaria pigmentosa is likewise not mentioned. Attention is called to these few points with the hope that in the next edition they may be incorporated, to the improvement of the book.

The Etiology, Pathology, and Treatment of Diseases of the Hip-joint. By Robert W. Lovett, M.D. Boston: G. H. Ellis, 1891.

This admirable little book of Dr. Lovett's secured the Fiske prize in June, 1891, and is a most carefully prepared treatise upon the various diseases of the hip-joint, with especial reference, of course, to tuberculous articular ostitis. He devotes, however, excellent chapters to acute arthritis and synovitis, as well as to arthritis deformans, Charcot's disease, congenital dislocations, and hysterical affections. His work shows careful consideration of the most recent pathologic views relating to local tuberculosis as it affects the bones and joints. His description of the invasion of the joint from tuberculous foci in the epiphyseal line of the femur accurately expresses the ordinary course of this most insidious lesion. He does not deny the fact that cases occasionally arise within the joint, but they are exceptional. The action of traumatism and heredity, both of which lessen the resistive power of the individual against the degenerative process, is well considered.

He divides the treatment into mechanical and operative, the mechanical methods being subdivided into—

(*a*) Protection.
(*b*) Fixation.
(*c*) Traction.

He argues in favor of traction both in the recumbent and erect postures, and wisely insists that any apparatus tending to limit motion at the hip must extend high enough to embrace the bones of the thorax.

With good reason he advises the use of axillary crutches and of a high shoe on the well foot even when the long traction splint is used.

The sentence on page 123 is especially to be commended. "The writer would gladly advocate in any way the necessity of greater joint-rest in connection with ambulatory traction treatment."

His description of the operative treatment of hip disease is meager and is limited to excision. No mention is made of the more recent treatment by iodoform injections into the joint and into the tuberculous tissue.

The paper and the style of the book is excellent, and the reproductions of the photographs (which are numerous) are in many instances exceedingly satisfactory. Altogether the work is most heartily to be praised.

A Dictionary of Treatment; or Therapeutic Index, Including Medical and Surgical Therapeutics. By William Whitla, M.D., Professor of Materia Medica and Therapeutics in the Queen's College, Belfast, etc. Revised and adapted to the Pharmacopeia of the United States. 8vo, pp. 920. Philadelphia: Lea Brothers & Co., 1892.

This is a book for the busy general practitioner. It is more than a therapeutic index, presenting as it does clinical therapeutics in its broadest aspect. The names of diseases and of prominent conditions and symptoms are arranged alphabetically, while under each title is presented a concise yet thorough consideration of the best and generally accepted methods of treatment, precedence generally being given to those the efficacy of which has been demonstrated in the experience of the author. No department of medicine has been ignored. Some of the articles are quite full, while none have been treated superficially. It is upon these facts that the usefulness of the work for the general practitioner depends. Thus, we find that the article upon Phthisis occupies twenty-four pages, while nine additional pages are given to the subject of Tuberculosis, including a consideration of phagocytosis and of the therapeutic employment of

tuberculin, of goat's blood, of the serum of dog's blood, of potassium cantharidinate and of zinc chloride; the article on Typhoid Fever occupies sixteen pages; that on Valvular Lesions of the Heart fifteen pages, while more than five additional pages are taken up with a consideration of the treatment of other morbid conditions of the heart; fifteen pages are devoted to Neuralgia, eleven to Syphilis, Cancer, and Insomnia, each; and ten to Bronchitis, Croup, Diabetes, and Rheumatism, each; Eczema is given nine pages; Lupus Vulgaris, eight; Ovarian Tumors receives eight; Inflammation of the Ovary, an additional three; the treatment of Stricture of the Urethra occupies seven, that of Intestinal Obstruction six, and that of Hernia six in addition; Locomotor Ataxia receives five pages; Conjunctivitis, four; Mastitis, four; Labor, three; and Abortion, three. An index of nineteen pages gives completeness to the work, and renders reference easy. Legitimately used, this book will be of great assistance to the medical practitioner.

The Hydriatric Treatment of Typhoid Fever, according to Brand, Tripier and Bouveret, and Vogel. By Chr. Sihler, M.D., Ph. D., Professor of Histology in the Medical Department of the Western Reserve University; formerly Fellow of the Johns Hopkins University, and Assistant in the Biological Laboratory. 12mo, pp. 340. Cleveland, Ohio: Chr. Sihler, 1891.

When the fellows that "only heard of it last night" become so enthusiastic over a therapeutic expedient, as has been the case recently in certain quarters with regard to the method of treatment of typhoid fever by systematic cold-water bathing, it is not unwise to return and give credit with due thanks to the original source.

For this reason we welcome Dr. Sihler's little book, in which, so far from claiming to be the discoverer of this method, which is unquestionably the treatment *par excellence* in typhoid fever, the author has been careful to give due credit to Brand, the originator, and to Vogel, Tripier and Bouveret, Glénard, and the other devoted disciples in Germany and France, to whom the final and full establishment of the method in professional recognition is due.

The object of the author—"to enable the medical profession of the United States to use the hydriat[r]ic method in the treatment of typhoid fever; to enable the physician to become familiar with the details of the method; to inform him about the modifications necessary in special cases; to give him a rationale for its mode of action; to state the results obtained by others"—has been well carried out, and despite the many unfortunate typographic blunders, and generally poor book-making, we can cordially commend the work to every practitioner who desires to be fully informed on one of the most important subjects in practical medicine.

There is hardly another instance in the history of medicine in which, despite the scoffing of the prejudiced, the blunders of the incompetent, and the sneers of the ignorant, a physician has for so long a period, so modestly, so courageously, and so scientifically persisted in a course which he knew to be right, as has Ernst Brand, of Stettin, and his name deserves to be enrolled in the short list of the benefactors of humanity.

The Comparative Anatomy of the Domesticated Animals. By A. Chauveau. Revised and enlarged by S. Arloing. Second English edition, translated and edited from the fourth French edition by George Fleming, C.B., LL.D., F.R.C.V.S. New York: D. Appleton & Co., 1891.

For nearly forty years Chauveau's *Traité d'Anatomie Comparée des Animaux Domestiques* has been the standard anatomy at the French veterinary schools, and for nearly twenty years Fleming's translation has occupied a like position in England and America.

Many works treating of the same subjects have appeared during the last two decades in both languages, but no author has equalled Chauveau in accuracy, thoroughness, or clearness of description; so that his work retains its high position. But an anatomy, however good originally, must grow old in twenty years, and it is, therefore, fortunate that a new edition has been issued.

The new Chauveau is larger and better than the old; the descriptions are revised, parts have been added, and new cuts inserted. As new features we notice the parts relating to the anatomy of the ass, of the camel, and of the rabbit.

Throughout the work the horse is taken as the standard, and most of the anatomic descriptions are based on this animal, while the others are studied by comparison.

The first chapter is devoted to defining the positions of the domesticated animals in nature and to general considerations, and is followed by descriptions of the various parts of the body, beginning with the organs of locomotion and ending with a chapter on embryology.

Minute descriptions are given for dissection, so that the book is adapted to the wants of the beginner as well as to those of the specialist.

The work is so perfect throughout that there is no single part to which we can call particular attention; and simply commend it as the best guide to the study of the anatomy of the domesticated animals.

The work comprises 1084 pages, and is nicely printed on good paper.

The Chinese: Their Present and Future; Medical, Political, and Social. By Robert Coltman, Jr., M.D., Surgeon in charge of the Presbyterian Hospital and Dispensary at Teng Chow Fu, etc. Illustrated with fifteen fine photo-engravings. 8vo, pp. viii, 212. Philadelphia and London: F. A. Davis, 1891.

Dr. Coltman writes in an entertaining way of his early interest in the Chinese, and of his final determination to visit that country as a medical missionary. He travelled through the country from Shanghai to Chinanfu, where he was stationed, and evidently used both his eyes and his ears. His remarks upon the manners and customs, the social habits, the food, the position of woman, and the vices of the Chinese are all instructive.

The most interesting chapters to the physician are those upon the diseases prevalent in China and upon leprosy. Dyspepsia and other diseases of the alimentary tract are the most common. Next in frequency are eye-diseases of all kinds. Variola is extremely common, Dr. Coltman declaring that nearly everyone has it at

some period of his life. Vaccination is practised, but the virus is in many cases impure, and the author believes that syphilis and tuberculosis are often communicated by it. Measles and scarlet fever occur occasionally; typhus is frequent in North China, and is associated with relapsing fever; cholera is epidemic every few years, and malarial fevers abound. In fact, most of the specific fevers and diseases are encountered, at least, occasionally.

As regards leprosy, Dr. Coltman thinks it cannot be very contagious or infectious, because, "in spite of the fact that the leper is under no quarantine regulation of any kind, leprosy has not spread to any appreciable degree in the last century." He believes, however, that it is in most cases hereditary; that it is inoculable, and that the previous saturation of the body with syphilis affords a favorable soil for the development of the disease.

We are rather surprised at his assertion that the Chinese are no more immoral than Americans or English. Private letters from the north of China had produced a very different impression.

Consumption—How to Prevent It and How to Live with It; Its Nature, its Causes, its Prevention, and the Mode of Life, Climate, Exercises, Food, Clothing Necessary for its Cure. By N. S. Davis, Jr., A.M., M.D., Professor of the Principles and Practice of Medicine, Chicago Medical College, etc. 8vo, pp. viii, 143. Philadelphia and London: F. A. Davis, 1891.

This little book has been written for patients—not for physicians. The author has sought to impart such information regarding the prevention of pulmonary tuberculosis and its hygienic management as he has found by experience that patients need. He accepts the tubercle-bacillus as the cause, and believes that a predisposition to the disease is inherited. He denies positively that it is contagious, says nothing about infection, and yet insists upon the greatest care in the destruction of the sputa; declares that a tuberculous mother should never suckle her children, and that care should be exercised to avoid milk from tuberculous cows. It has always seemed to us difficult to deny the possibility of contagion in an infectious disease.

Much useful information is given as to the choice of climate, food, exercises, and clothing. Many will not agree with Dr. Davis that those who suffer from frequent hemorrhages are benefited by a sea voyage, and we think he speaks too highly of the general good effects of sea-air in pulmonary tuberculosis.

The book, as a whole, will be very helpful to patients who need elaborate instruction and are intelligent enough to follow it.

Food in Health and Disease. By I. Burney Yeo, M.D., F.R.C.P., Professor of Clinical Therapeutics in King's College, London, etc. Small 8vo, pp. x, 583. Philadelphia: Lea Brothers & Co.

Doctor Yeo is so favorably known both as a clinician and as a writer on dietetics that we have learned to look with confidence and authority upon any work emanating from his pen. As the digestive canal is so commonly the portal of entry, directly or indirectly, of disease, a study of conditions in which it takes a conspicuous part must receive most earnest consideration. The preservation of health implies the maintenance of an equable adjustment between income and expenditure. It is established that the underfed fall ready prey to disease; the overfed and the badly-fed may be included in the same category. Nothing can be clearer than the inference that if immunity from disease depends, among other things, upon the quality of the bodily fluids, such protection can be most readily secured by the establishment of the highest nutritive condition. This end is not to be attained by means of drugs, but by the judicious use of food. The art of dietetics is even more important than that of therapeutics; it is the office of the former to aid in repelling as well as in curing disease. Even in many conditions of disease the best treatment consists in encouraging through the nutrition the natural tendency to recovery. Dr. Yeo fully considers the subject of food in all its varied aspects: its nature, origin, and purposes; its digestion, assimilation, and utilization; its cooking, preparation, and preservation. An appendix contains dietaries for hospitals and invalids. A careful perusal of this work will repay those interested in the philosophic, physiologic, and therapeutic aspects of food.

A B C of the Swedish System of Educational Gymnastics. A Practical Handbook for School-teachers and the Home. By Hartvig Nissen, Instructor of Physical Training in the Public Schools of Boston, etc. With seventy-seven illustrations. Small 8vo, pp. vii, 107. Philadelphia and London: F. A. Davis, 1891.

Lack of physical training is a recognized defect in our educational system. When we consider that a healthy body is not less important than a healthy mind, the necessity of systematic physical education makes itself apparent. Fortunately, courses in physical exercise have been incorporated into the curricula of the schools of some of our cities, and the innovation can only be attended with beneficial results. The most meritorious procedure may, however, be rendered nugatory by faulty or inefficient methods of application. By simplicity of description and generosity of illustration Mr. Nissen has succeeded in placing within the reach of parents and teachers a manual that will greatly facilitate the systematic physical training of children and others, at home and in school. The spirit of the work is most heartily to be encouraged. Only the Swedish system is described. It is considered the best for schools and homes. For colleges, universities, and gymnasia a combination-system is thought better suited.

The Pathology and Prevention of Influenza. By Julius Althaus, M.D., M.R.C.P., London, Senior Physician to the Hospital for Epilepsy and Paralysis, Regent's Park. New York: C. P. Putnam's Sons, 1892.

This brochure, of some sixty odd pages, is an amplification of a paper on "The Pathology of Influenza," which the author read before the Medical Society of London, during the latter part of 1891. The paper is

devoted to demonstrating (1) that the symptoms of influenza are owing to the action in the system of a special poison secreted by a pathogenous bacillus; (2) that this poison has a special affinity for a definite center of the nervous system, which is irritated and depressed by it; (3) that an antidote to neutralize the effects of the poison is formed in the blood of the patient, and tends to effect a spontaneous cure of the disease; and (4) that the nearest approach to this antidote that we at present possess appears to be animal vaccine-lymph, which should, therefore, be used as a preventive of influenza.

Whilst some of the author's conclusions are based upon theory rather than fact, the work, as a whole, is interesting and instructive. Many novel suggestions are made in the work, of which time and experience alone can test the utility.

The Pocket Pharmacy, with Therapeutic Index. (A *Résumé* of the Clinical Applications of Remedies adapted to the Pocket-case, for the Treatment of Emergencies and Acute Diseases.) By John Aulde, M.D., Member of the American Medical Association, of the Medical Society of the State of Pennsylvania, of the Philadelphia County Medical Society, etc. 12mo, pp. 204. New York: D. Appleton & Co., 1892.

The author states that his work is "in the nature of a plea for smaller doses, to be administered in accordance with physiological deductions," and that it is "the outgrowth of personal experience in general practice." He likewise states that "the book will prove of value when the physician carries a pocket-case, as he will be enabled to exhibit the required medicament at once, instead of waiting for a messenger to obtain it from the nearest pharmacy." The author, furthermore, "believes that it will prove especially useful to the recent graduate, who, while supposed to be intellectually rich, is often technically poor. To write in a proper manner a complicated prescription in the presence of a patient, is likely to cause a mental strain not exceeded in passing the examination in practice or materia medica."

Until our colleges increase their facilities for bedside instruction, and until our States have proper examining boards, there will, indeed, be a large demand for books of this kind. The only addition that we might suggest, in order to render the book still more useful to one unable to withstand the strain of writing a prescription in the presence of a patient, would be some infallible machinery for making a correct diagnosis.

Surgical Diseases of the Ovaries and Fallopian Tubes, Including Tubal Pregnancy. By J. Bland Sutton, F.R.C.S. Philadelphia: Lea Bros. & Co., 1892.

This book has appeared most opportunely. Hitherto the profession has been furnished with the clinical experiences of various observers, viewed in various lights, according to the fancy of the writer, until considerable confusion has resulted. The writer in this little work has undertaken to present in a concise form the facts and theories collected from the most reliable sources. The pathology of the ovaries and Fallopian tubes is obviously of great importance; the author, with praiseworthy originality of description and arrangement, has attempted a careful exposition of the relation between the clinical and pathologic aspects of the subject.

The chapter on ovarian hydrocele is of special interest, and Part III, devoted to tubal pregnancy, deserves a place in the classic literature of medicine. The simplicity of the author's method of treating this branch has done away with the intricacies of classification and the confusion that belong to the development of a new subject. It is clear that the secret of the author's insight into the subject lies in the care with which he has devoted himself to researches in pathologic and comparative anatomy.

Nursing in Abdominal Surgery and Diseases of Women. By Anna M. Fullerton, M.D. Philadelphia: P. Blakiston, Son & Co., 1891.

In this work Dr. Fullerton has followed her accustomed clearness and comprehensibility of style. She has furnished a long-desired handbook from which nurses, in their moments of leisure and opportunities for study, can acquire that knowledge that is demanded from them in times of emergency. Every operator has experienced the interruptions and drawbacks that arise during a critical operation from the inefficiency of his assistants. This often comes, not from any want of interest or from negligence on the part of the nurse, but from the want of practicalness in her training. Every nurse, on the other hand, has felt the keen sense of chagrin at finding herself deficient in knowledge which she had thought within her possession, at the moment when she has been most in need of it. Dr. Fullerton has clearly discerned the requirements in the training of nurses for this special work, namely, the inculcation of knowedge that will give an intelligent idea of the work before them, and the insistence upon habits of promptness and forethought. For both the physician and the nurse this book presents the important points in a clear and impressive way. The chapter on asepsis and antisepsis is well written, and brings the subject forcibly to the attention of the pupil-nurse.

Essentials of Medical Physics. By Fred. J. Brockway, M.D., Assistant Demonstrator of Anatomy at the College of Physicians and Surgeons, New York. Philadelphia: W. B. Saunders, 1891.

This volume is number twenty-two of Saunders's Question Compends, and is intended for use in preparing students for examination in physics. The author has endeavored to compile a work which shall occupy a position midway between the elementary books on the subject, which do not contain all that is necessary for the student to know, and the larger works—such as Ganot's—which are too voluminous to be available as text-books.

In our opinion, the author has dealt with a subject which to the student is usually surrounded with more or less difficulty, and in a manner that will make the theme not only comparatively easy, but also of interest. Of course, the present volume is but an epitome, and as such its great value is as a supplement to a regular course of lectures or of study, in order that the student

may be enabled to review the salient points of physics in a short time.

The book contains one hundred and fifty-five illustrations, and has a comparatively complete index.

Lessons in the Diagnosis and Treatment of Eye Diseases. By Casey A. Wood, M.D., Formerly Clinical Assistant, Royal London Ophthalmic Hospital (Moorfields); Microscopist and Pathologist to the Illinois Eye and Ear Infirmary; Professor of Ophthalmology, Post-Graduate Medical School; Oculist and Aurist to the Alexian Brothers Hospital, Chicago. Small 8vo, pp. x, 154. Detroit: George S. Davis, 1891.

Careful reading of this little volume shows us that in it we have a good and well written, though unfortunately unfinished, book. Particularly are to be recommended the terse and comprehensive lessons on Diseases of the Cornea and Sclerotic, and on Glaucoma; while that on the Ocular Affections in General Diseases is worthy the perusal of anyone interested in the subject.

We can unreservedly offer this manual as an excellent companion to freshen the mind of the advanced ophthalmologist, and as a wise counsellor to safely guide the general practitioner and medical student through the mazes and pitfalls of modern ophthalmology.

Essentials of Medical Electricity. By D. D. Stewart, M.D., and E. S. Lawrence, M.D. Saunders' Question Compends, No. 23. Pp. 158. Philadelphia: W. B. Saunders, 1892.

The perusal of this little book is apt to result in a genuine surprise to the reviewer, as the authors have evidently aimed at much more than an artificial aid to cramming. Throughout the whole of the brief space at their command they show evidences of a discriminating knowledge of their subject, and while the work is primarily for undergraduates, the principles are so well presented that it furnishes an excellent introduction to this study in the hands of a practitioner. The details for the treatment of individual diseases have not been slighted, the originality of some of them showing that imprint of experience so often wanting in book-writers. Considering the elementary character of the work there is, nevertheless, entirely too much space devoted to the historical part of the subject, both in the description of cells now unused and in the reproduction of full-page illustrations from a work that was old when the dynamo was discovered.

CORRESPONDENCE.

CHICAGO.

Commencement Exercises of Chicago Medical Colleges—Mortality Statistics of Chicago—The World's Fair and the Medical Profession.

The forty-ninth annual commencement exercises of Rush Medical College were held at Central Music Hall, March 29th. It was a memorable gathering, for it was the largest class in the history of "Old Rush," numbering 142. Dr. E. L. Holmes, president of the College, delivered the doctorate address. Professor Roswell Park, of Buffalo, N. Y., was announced as an honorary member of the class.

The exercises of the tenth annual commencement of the College of Physicians and Surgeons were held at the Grand Opera House on the same date. The degrees were conferred by the president of the College, Professor A. Reeves Jackson. The graduating class numbered 42. The doctorate address was delivered by Professor Bayard Holmes.

The twenty-second annual commencement of the Woman's Medical College took place March 28th at Central Music Hall. Dr. Henry Wade Rogers, president of the Northwestern University, conferred the degrees, the graduating class numbering 19. The prizes were distributed and the hospital announcements made by Professor Charles Warrington Earle, dean of the Faculty.

Dr. I. M. Neely, registrar of vital statistics, has prepared his report to the State Board of Health of the number of deaths in Chicago during 1891. The report shows a total of 27,801. Mrs. Rose Armstrong died at the age of 110 years. Joseph Miner was 108 years old at the time of his death. Two others had passed the century mark—Maurice Lee, Catherine Butler, 101. Seventy-eight persons had passed the ninety mark. A list in part of some of the causes of death follows: Pulmonary tuberculosis, 2149; pneumonia, 2744; scarlet fever, 269; typhoid fever, 1946; cholera infantum, 1224; delirium tremens and alcoholism, 141; railroad accidents, 331; other accidents, 621; suicides, 248; homicides, 60; sunstroke, 30; under five years old, 12,886; colored residents, 375.

The World's Fair Entertainment Committee of the Medical Profession of Chicago recently met at the Sherman House. This committee has undertaken preparations for extending hospitality to members of the profession visiting the World's Fair by means of medical headquarters, and in exceptional cases by the giving of banquets and receptions. The following reported themselves as permanently authorized to act for their respective societies: Dr. John E. Owens, Dr. A. E. Hoadley, and Dr. J. B. Murphy, representing the Chicago Medical Society; Dr. Harold N. Moyer, Dr. D. R. Brower, and Dr. C. W. Earle, representing the Practitioners' Club; Dr. William E. Clark, Dr. C. D. Wescott, and Dr. A. H. Foster, the Pathological Society; Dr. J. H. Etheridge, Dr. F. E. Waxham, and Dr. L. L. McArthur, the Gynecological Society; Dr. T. T. Nelson, and Dr. Archibald Church, the Medico-Legal Society; Dr. J. C. Cook, Dr. H. H. Deming, and Dr. Milton F. Coe, the South Side Medical Society; and Drs. Hektoen, Winthrow, and Holmboe, the Scandinavian Medical Society.

NEWS ITEMS.

Marriage of Cousins.—To a correspondent: Does not the editorial in The Medical News, January 23d, answer your query?

For Poor Sick Children.—The Managers of the Children's Seashore House at Atlantic City desire to extend its benefits to the largest possible number of invalid children. With this object in view they offer to receive, free of charge *during June*, as many bedridden or crippled children from the hospitals, public institutions, and private homes of our city (Philadelphia) and vicinity as their institution will accommodate.

Application for the admission of such children should be made in writing to the "Physician in charge of the Children's Seashore House." Until June 1st his address will be 332 South Fifteenth Street, Philadelphia, and after June 1st, Atlantic City, N. J. Early application is desirable, and no child should be sent to the institution without previous application. The above offer does not include railroad fares.

Railway tickets are sold to patients coming to the institution at the rate of twenty-five cents for children and fifty cents for adults, each way. These can be obtained only by means of the requisitions upon the ticket agents, which are always furnished with the orders for admission.

New Chairs and Professors at the Jefferson Medical College.—The Board of Trustees of the Jefferson Medical College, at their meeting, April 7, 1892, instituted a chair of Clinical Gynecology, with a seat in the Faculty, and elected to the new chair Dr. E. E. Montgomery, who has been for a number of years professor of gynecology in the Medico-Chirurgical College. They also established the following clinical professorships, electing Dr. F. X. Dercum, professor of nervous diseases; Dr. E. E. Graham, professor of children's diseases; Dr. H. Augustus Wilson, professor of orthopedic surgery; Dr. H. W. Stelwagon, professor of dermatology; and Dr. W. M. L. Coplin, adjunct professor of hygiene.

Public Baths in Boston.—The *Boston Medical and Surgical Journal* states that a company, to be known as the Boston Bath-house Company, is soon to be incorporated to establish baths for the poor of Boston, following the steps of the chief European cities and the recently established People's Baths in New York. There is already a small establishment of this kind in Boston, where, during the first year, 3000 men, women, and children made use of it. It is hoped that after the baths are established they will be self-supporting. About $40,000 are needed for the establishment of the institution.—*Medical Record.*

The Medical Association of Georgia will hold its forty-third annual session at Columbus, Ga., April 20, 21, and 22, 1892. An interesting program is announced. Members of the medical profession are cordially invited to attend the session. Dr. G. W. Mulligan, of Washington, Ga., is the president of the Association; Dr. Dan. H. Howell, of Atlanta, secretary.

The Association of the Alumni of the Medical College of the State of South Carolina was organized at Charleston on March 11th, with the object of increasing the usefulness of the College, of establishing a well-equipped laboratory for instruction in biology and pathology, of cultivating a spirit of professional amity, and of endeavoring to uphold the highest standard of medicine. Dr. Eugene Wasdin, of the U. S. Marine-Hospital Service, was elected president, and Dr. C. B. Calson, of Charleston, secretary and treasurer.

The Iowa State Medical Society will hold its forty-first annual session at Des Moines, May 18, 19, and 20, 1892. A large number of papers in the various departments of medicine is announced. Dr. George F. Jenkins, of Keokuk, is the president and Dr. J. W. Cokenower, of Des Moines, secretary.

Obituary.—DR. JOHN S. STEWART, of Philadelphia, the son of Dr. Samuel S. Stewart, of Allegheny City, Pa., died on April 11th of pulmonary tuberculosis, at the residence of his uncle, Dr. Wm. S. Stewart. Dr. Stewart was born in Allegheny County, Pa., November 19, 1864. He was educated at the Western University and at the Medico-Chirurgical College, of Philadelphia, graduating at the latter institution with the highest honors of his class in 1885. He had endeared himself to his many patients and friends by a manliness and gentlemanliness and a combination of courtesy and self-respect rarely found. He was a successful and an exceptionally skilled ophthalmologist.

MENTAL IMPROVEMENT FOLLOWING OPERATION ON THE SKULL.

BY HUGO ENGEL, A.M., M.D.,

CONSULTANT IN NERVOUS DISEASES AT ST. JOSEPH'S HOSPITAL AND IN CHARGE OF THE INFIRMARY FOR EPILEPTICS, ETC.

BRAIN-SURGERY, though still in its infancy, is rapidly advancing. The conditions under which the skull should be opened for the purpose of removing morbid states are being determined more and more accurately, especially by such careful and experienced men as Von Bergmann,[1] Horsley,[2] and Macewen,[3] and the field of usefulness for such operations as the enucleation of tumors, the emptying of cerebral abscesses, and the destruction of irritating foci in the cortical motor area is becoming limited more strictly, as we understand better the indications that alone should justify us in attempting such hazardous procedures as the introduction of the surgeon's knife into the encephalon. Although we have learned to look upon these operations as by no means free from danger, and while many surgeons have published their successful as well as their fatal cases,[4] comparatively little attention has been paid—and that little but recently—to one important subject, viz.: the consideration of the possibility of altering and improving psychic disturbances; to influence, therefore, the highest function of the brain, the mental sphere, by operations on the encephalon itself. What has been done in that respect has consisted mainly in the resection of the skull, when the latter seemed to be an obstacle to the normal development of the convolutions beneath it, or in the cutting away of diseased cortical tissue.

Especially in cases in which too early ossification of the skull caused a retardation in the physiologic growth of cortical tissue, or in which the too rapid closure of the anterior fontanel had given rise to microcephalic conditions, or in which the apparent malformation of the bony enclosure of the brain was thought to be responsible for idiotic and similar morbid states, have operations been performed with more or less success.

Here again may be mentioned a number of skilful operators who have contributed to the literature of the subject.[1]

Attempts have also been made to restore the mental equilibrium when, in consequence of chronic hemorrhagic pachymeningitis, localized accumulations of blood seemed to have caused dementia. As Von Bergmann[2] reports, Ceci[3] at a meeting of Italian surgeons first recommended operative interference in these cases, while Huguenin[4] has tried to prove that the pachymeningitic changes often met with in dementia paralytica (non-specifica?) are due to primary subdural hemorrhages. In this connection Keen's article on "Intra-cranial Lesions"[5] is of special interest, as it determines the main diagnostic points and the indications and contra-indications of operative interference and mentions the results to be expected from the latter.

It is the locality, the exact seat of the morbid lesion, which is of importance in all pathologic states concerning the encephalon or its bony enclosure, and here the gray cortical tissue plays a far weightier role than the white matter, as it has been found that certain impressions and impulses of which the conducting tracts were destroyed, selected new paths along which to travel. Every part, however, of the cortex has its definite function and can neither be gradually encroached upon nor be

suddenly destroyed or injured with impunity. Cases in which the diseased cortical motor area has been excised without giving rise to permanent palsies are no proofs to the contrary, and do not belong to this category; if anything, the transient paralysis resulting from such excision is in favor of the facts stated. For in these cases the same convolutions on the opposite, non-affected side, or more deeply-situated cells on the side of the lesion, assume the functions of the parts destroyed. Here the healthy centers, during the duration of the disease, have gradually become accustomed to perform the functions of the portions attacked by the morbid lesion.

Probably the convolutions on the right side exactly in a situation corresponding with those on the left side in right-handed persons in which the complicated speech-apparatus has its center (lower left third, Broca's, island of Reil) receive the same impressions as those active in the opposite hemisphere, but more feebly, and their associated connection with all other will-centers is not so intimate, but becomes gradually developed, as those in the left frontal lobe more and more fail to perform their duties, yet never in so high a degree. In this we find an explanation of the return of articulated language—though not a perfect or complete restoration—when hemorrhage destroys the speech-centers on the left side.

The functions of many convolutions are known, but what those of the frontal lobes are—excepting those mentioned—we can only conjecture. It is in these gyri that abstract ideas are formed. Here reside the centers of the highest intelligence; here thoughts originate. What we call quick perception, genius, talent, poetic feeling, narrow-mindedness, immoral character—all these dwell here. And here also is the only region in which Nature has made such an arrangement in the bony enclosure as to allow for more space, should such become necessary in later life, when the skull has already become a solid, unyielding whole. In the frontal sinus over each eye the laminæ are thinner; they may give way, and not only may the hollow spaces be encroached upon, but the outer skull may be even driven outward. What are called "bumps of knowledge" always receive their fullest development and final shape between the twenty-fifth and thirty-fifth year, and when genuine, they are observed to be especially prominent only in persons of a high order of intelligence and possessing a quick perception. And though not invariably specially large, I have always noted them in autodidacts, in whom earlier education had been neglected, but who finally overcame all obstacles and acquired considerable learning, principally from books.

Further discussion would lead us too far, but we may say that slight alterations in the gyri of the frontal lobes, whether in the upper gray layers of cells or in those lower down, nearer the white matter, a very little pressure upon them, or some immovable resistance offered to their development, will often produce serious consequences in that quarter and create mental disturbances. The following case gave rise to these reflections.

Robert B., fourteen years old, was brought to my clinic May 25, 1891. The family history showed no taint, and no organic disease existed. The boy was healthy and vigorous and mentally bright until his sixth year, when he was seized with convulsions. There was no gradual transition from *petit* to *haut mal*. Without any discoverable cause, the attacks began one day at the period of his life referred to, and have since never ceased for any length of time. Sometimes they were milder, *i. e.*, the clonic spasms were not so severe; at other times the seizures were very violent. While he had met with a number of accidents, due to the fits, and while his head and face showed many a scar, old and recent, deep and superficial, the many injuries he received had no causal connection with his disease, which preceded all accidents.

He first had only one attack in two weeks, then one a week, then several in that time, then one daily, and finally from four to ten every day; occasionally many more, as many as twenty-one in the twenty-four hours, and especially during the last two years they had greatly increased in severity and also occurred with frequency during sleep.

The starting movement, simultaneously with the suddenly developing unconsciousness, generally consisted in an extreme rigidity of both arms, which were forcibly extended and stretched out in front of him. Sometimes one arm first became stiff, the next time the other, but there was no regularity in this, the right and left arm changing about in the most hap-hazard manner. The hands were mostly clinched, but now and then the fingers were extended and as rigid as the arms. The movements, however, invariably commenced in the upper extremities, and their sudden rigidity always ushered in the seizure, which otherwise did not differ from ordinary violent attacks of *epilepsia gravior*.

But the most interesting point in the case was the following: Statistics have shown that one-half of all epileptics enjoy the best of health and are remarkable for their bright intellect.[1] Because of the frequency with which even Herculean build and unimpaired mental faculties are found to be associated with the severest forms of *grand mal*, the disease *eo ipso* is not looked upon as a destroyer of memory, an impairer of intellect, and an underminer of physical vigor. On the contrary, when such disturbances occur in the course of the "falling sickness" they are to be ascribed to other factors. The same lesion that causes *petit* or *haut mal* may also be responsible for the complications of epilepsy. And we may make this statement, as im-

[1] Nothnagel, art. "Epilepsy," in Ziemssen's Cyclopedia, vol. xiv, p. 253 et seq.

portant from a diagnostic standpoint: If the symptoms (loss of memory, slow perception, retarded mental development, idiocy, dementia, failing health, general debility, etc.) accompany the epileptic malady from its commencement and slowly become more and more apparent, they are complications, and one pathogenic cause produces both; but if these phenomena show themselves only after the "falling sickness" has lasted some time, they are sequelæ and due to the epilepsy.

Until the time of the commencement of the convulsions Robert's intellect was of a higher order than is usually met with in children of his class—his father being a laborer. But with the occurrence of the convulsions a great change began simultaneously in the mental sphere. He became dull and vicious, and long before the fits had become very severe and numerous his intellect was clouded, until he finally seemed simple and almost idiotic, and at times became maniacal.

When I first saw him the expression of his face denoted imbecility and low cunning; a vulgar leer was in his eyes, which otherwise always looked at the ground as if dreading punishment; he glanced in a peculiarly shy manner at everyone; the movements of his facial muscles were heavy, sluggish, and vulgar in the extreme. Several times in a day he broke out into a kind of maniacal behavior, when he used the vilest language, destroyed articles of furniture, and hit his mother. Upon being remonstrated with he put out his tongue and acted like a hardened criminal. There always was a sinister expression of the face; his walk was heavy and clumsy, like that of a big man, qualities which characterized also his speech.

One glance by a careful observer sufficed to recognize a peculiar conformation of his skull. It seemed as if the latter, at the upper central part of the frontal and the upper anterior third of each parietal bone, while soft, had been crushed in by some weight, and as if the same force had pressed the two parietal bones in front closer together—this changed formation of the skull continuing until ossification had been complete. The skull, besides, was also far more massive than, considering the age of the boy, it should have been. I have never seen a case that thus impressed me with the fact that a premature closure of the anterior fontanel, a too rapid bony union at the sagittal and coronary sutures, and a too early and too rapid morbid formation of the bone had prevented the normal development—the expansion—of the cortical layers of the anterior lobes and of the upper and anterior portion of the parietal lobes, as happened in this boy's case. The mental development had been arrested and had been forced to sink below the usual level of that met with in the human being at the age of eight years—the boy then being fourteen.

Excepting his being endowed with speech—and of this he made, as indicated, but a clumsy use, so that it sounded more like a grunting, and wanted all modulations of voice and accent, often resembling the snapping and growling of an angry animal—he seemed to be a savage young monkey rather than a boy.

Under a systematic use of the bromides the convulsions greatly diminished in severity and frequency, without there being the slightest change noticeable in the mental sphere. Though we had no hope of improving the epilepsy, Dr. John H. Packard, whom I consulted because of his great experience in all kinds of injuries and operations concerning the skull, agreed with me that the bony impediment to the expansion of the brain should be removed, and as most cases in which both sides of the skull had been operated upon at once had terminated fatally, we concluded to resect first on one, and at a later time on the other side.

O—N. Piece of skull resected.

Both operations were performed at St. Joseph's Hospital (the first August 10, 1891, and the second November 17, 1891) by Dr. John H. Packard, assisted by the resident physicians, Drs. José Samaniego and W. R. Parker. The accompanying drawings will show the pieces of bone, O—N, removed on each side. The bone was more than twice as thick as it should have been and of a calcareous nature; there seemed but little animal tissue in it. To the touch it gave the feeling as of hardened mortar to which much chalk had been added, and of the smooth, hard laminæ there was no trace.

Drs. Parker and Samaniego made the following report, which though condensed to elucidate only the important data, yet shows the progress of the case after the operations:

When Robert B. entered, August 3, 1891, the hospital, he was very unmanageable, having to be carried to the ward and made to stay there by the employment of force and of the most vigorous measures. His language and actions toward his parents and attendants were shocking in the extreme. During the weeks preceding the first operation he had many attacks a day, five of which always were very severe, *lasting from thirty to sixty* minutes. The wounds after both operations remained perfectly aseptic, and the patient each time made a rapid recovery. For five weeks after the first and for two weeks after the second operation he had no attacks; after that he had one a day—at present about two per week—but far milder than the former seizures, consisting only of loss of consciousness, with slight twitchings instead of the terrible clonic spasms that previously occurred.

One peculiar observation was made: While *before* the operation the boy, at the beginning of an attack, was always thrown *forward* with great force—to which the many scars testified; *after* the operation, he invariably fell *backward* and the violent force ceased; he rather glided to the floor instead of being hurled forward.

The temperature after both operations never went above 100°.

We now come to the main point, the result of the operations as regards mental improvement. As the consequences of the first operation were the same as those of the second, only less marked, we will note the effects of both as a whole.

We may truly state that the result was remarkable, and exceeded our most sanguine hopes. From an idiotic, sulking, and savage individual, given to maniacal outbreaks and evidently utterly wanting in all finer feelings, Robert changed to a bright, lively, and good-natured boy, with eyes beaming with pleasure and gratitude. What first attracted attention, and was especially noticeable a few weeks after the second resection of bone, was the complete disappearance of the constant frown and of the scowl that had been habitual with him, and the frank and open look with which he greeted his physicians. There now was a smile on his face; he no longer had his sight riveted to the floor when questioned, but directed it straight at the speaker, and his eyes wore a happy expression. All his former irritability and morose temper had vanished as if by magic; every act of his evinced good-nature, and he enjoyed a joke and himself tried to practise one on others, instead of being bent only on mischief and endeavoring only to injure others. When the hand was offered him he shook it heartily, while formerly he did not seem to comprehend what hand-shaking meant. To all inquiries he made intelligent replies, and it was plainly to be noticed that he tried his best to please; one could observe his earnest efforts to describe his symptoms, while before the operation his custom had been to sulk, so that no information whatever could be gleaned from him.

I have mentioned his peculiar, clumsy walk, which resembled more the step of a young elephant than that of a boy. The first time that I saw him in the hospital out of bed, about three weeks after the second operation, he was just running up a flight of stairs, skipping two or three at each jump, and he appeared as active and agile as any other lively boy at his age, and to enjoy life just as much, while previously his very existence seemed to be a burden to him.

Of great importance was this observation. While he had become bright and intelligent, the very opposite of what had once characterized him, his gaiety, the plays and occupations he liked best, belonged more to a boy six years his junior. In reporting his general mental state, while attending him at the clinic, I took occasion to note that his actions were those of a man forty years old; after the obstacle to the expansion of the gray cortical tissue of the brain had been removed, all heaviness and clumsiness seemed to cease at once as if by a miracle; every motion, the play of his features included, became active and quick, but his whole behavior was that of a boy eight years old—as if the brain had been able to develop up to that age and had then remained stationary under a cloud, as it were, until with the removal of the impediment the brain again began to make further progress, starting where it had left off. He now expressed a wish to go to school, while previously the family could not force him to go thither. His perception quickened, and, in a few words, it was the greatest change that I have ever known to occur in the mental state of any individual, and not only the most marked but also the most sudden.

The convulsions he now has, reduced under treatment with argenti nitras to from one to two a week —some weeks of late none—are almost of the nature of *petit mal;* there is no longer any force in the seizures, and a few twitchings constitute the whole clonic element of the attack, while the tonic rigidity formerly present is completely absent.

If the cases are carefully selected a wide field is opened to cerebral surgery. But we should cease trephining unless—(1) there is evidence of depressed bone as the consequence of an injury, or (2) there is malformation, or (3) there is proof of too early ossification. In other words, unless we know that the pressure of the bony enclosure causes the epileptoid seizures, trephining and linear craniotomy (two trephine openings and the removal of the intervening piece of bone or resection of a part of the skull performed in no matter what way) should not be resorted to. We may also call attention to the fact that after such an operation the fits are likely to remain away for from one to six weeks, when they will return, and that this happens even in cases in which linear craniotomy was not indicated at all and is bound to prove useless. Such cases ought, therefore, not to be reported until several months have passed by after the operation. In most cases, besides the resection, the cortical layers responsible for the attacks must be cut away—a very difficult procedure, because of the great skill and experience (and these often do not

suffice) needed to exactly locate the seat of the irritating focus. There also is a great difference, as concerns the danger of the operation, between simple resection of bone and penetrating through the dura into the cavity of the skull.

A careful search for lesions, as in Robert B.'s case, should always be instituted when the mental impairment began simultaneously with the outbreak of the epileptic disease, when we have evidence, therefore, that the same morbid cause within the encephalon is responsible for the deterioration of the intellect and for the convulsive seizures. And this happens most frequently in cases of microcephalus due to the narrow limits of the cavity of the skull, in which the brain needs more space for its normal development.

THE MECHANISM OF IMMUNITY, WITH ITS CLINICAL LESSONS.

By B. K. RÁCHFORD, M.D.,
CLINICIAN TO CHILDREN'S CLINIC, MEDICAL COLLEGE OF OHIO, CINCINNATI, OHIO.

In The Medical News of February 2, 1889, in discussing the immunity conferred by an attack of a self-limited parasitic disease, I said: "It occurs to me that *the causes* which give to these diseases the characteristic of self-limitation and check their progress must be the same that give the after-immunity. . . . . These self-limited diseases are therefore terminated by the acquisition of a temporary immunity on the part of the patient, which continues for a longer or shorter time protecting him against future attacks." Dr. Charles Bouchard, in a paper read before the Tenth Internal Med. Congress, Berlin, 1890, gave expression to the same idea in almost the same words. He said, "The cure is the first manifestation of the acquired immunity." If this proposition, which seems almost axiomatic, be true, then it follows that all self-limited parasitic diseases confer immunity, and conversely, parasitic diseases not self-limited do not confer immunity. This conclusion is a portion of the *Law of Immunity* that I published[1] in 1889. This law, I yet believe, in the light of recent investigations, approaches as near the truth as any condensed statement at present can. It is as follows: "All self-limited parasitic diseases confer immunity, and the completeness and the length of the period of the immunity will be in direct proportion to the severity of the constitutional symptoms of the attack which conferred the immunity." I was led to formulate this law by the study of two self-limited diseases, which were thought by many able clinicians to give predisposition to, rather than immunity from future attacks, viz., erysipelas and diphtheria. In the papers referred to I have given a portion of the evidence and argument that convinced me that both of these diseases conform with the law mentioned.

The idea, as expressed in the law, is that a severe attack of a self-limited parasitic disease gives at least complete temporary immunity, but it does not fix the time that this acquired immunity may last; this period varies greatly in different diseases and is not subject to any general law. As to period, the law only comprehends the idea that the complete temporary immunity resulting from a severe attack of any of the self-limited parasitic diseases remains a complete protection for a longer or shorter time and after this affords a partial protection till the cause of the immunity has entirely disappeared, when the animal is again as susceptible to the disease as it was before the attack. The protection afforded by acquired immunity, after the period of complete immunity has passed, may be likened to a cone—this cone of immunity tapering to a point as time goes on; when the point is reached no protection remains, but previously to this the animal was partially protected and susceptible to milder attacks of the disease, the severity of these modified attacks depending on the size of the cone of immunity at the date of the attack—or in other words, on the nearness of the second attack to the attack that conferred the immunity. The further removed the second attack is from the first, the more severe it will be, that is within the limits of the immunity-period. After this period has expired, time does not increase the severity of the second attack.

This law, I think, will be of value as a working hypothesis in the field of experimental clinical medicine. But that we may understand the application of the principles underlying this law to the study of clinical medicine, it will first be necessary for us to inquire more closely into the nature of parasitic diseases, and *the causes* that give to them the characteristic of self-limitation.

At present, it is everywhere believed that in all parasitic diseases there is an antagonism between the parasites and the cells of the animal attacked, and that this warfare between the cells and the parasites and the resulting changes caused thereby represent the essential pathologic process in all mycotic diseases.

In the publication of 1889, referred to, I expressed the opinion that this contest was an extra-cellular one, and I then offered the following modification of the Metschnikoff theory as the best explanation of the nature of this process.

1. There is an uncompromising warfare waged by the cellular elements of the body against the invading bacteria.

2. The destructive influence of the bacteria is

[1] Cincinnati Lancet and Clinic, April 29, 1889, p. 630.

exerted chiefly if not exclusively through the agency of chemical poisons.

3. The cells in like manner exert their destructive influence through the agency of chemical products that are formed by reason of the increased biologic activity of the cells. This function of the cells is called into activity by the action upon them of the chemical products produced by the bacteria—a function called forth in self-defence.

4. This contest between bacteria and cells occurs *outside* and not inside the protoplasm of the cells.

5. When the cells, through the agency of chemical poisons, kill the bacteria, the "phagocytes" dispose of the dead. When the bacteria, by chemical products, destroy the cells, the former likewise feast upon the dead cells.

The foregoing theory, which I expressed three years ago, is in accord with the recent brilliant experimental work[1] that has added so much to our knowledge of the parasitic diseases. And in the argument that follows I have assumed that this theory comprehends the important principles underlying our present knowledge of these diseases.

In the study of acquired immunity we are interested in this intercellular contest only when the victory is obtained by the cells. The pathogenic bacteria gain entrance into the body and not only live there but also do more or less harm with the special poisons that they produce in the struggle with the cells for existence. The cells, on their part, are making every effort to destroy or render harmless the intruding bacteria. This they do by producing chemical substances, which have a destructive influence on either the bacteria or their products. This contest between cells and bacteria is one that knows no truce. It is a war of extermination. Both use similar weapons, viz., chemical substances, which are produced for the occasion. After a time the cells obtain the advantage, and the bacteria and their products are destroyed. This victory is by reason of the fact that the cells are able to secrete a substance that is more detrimental to the life and functions of the bacteria, than is the substance secreted by the bacteria to the life and function of the cells. With the victory of the cells the disease subsides and immunity begins. Upon what does this cure of the disease and the after-immunity depend? The answer is plain: Upon the superior functional activity of the cells. The cells in this contest have acquired a certain impressibility, a power to act and readiness for action, which enables them to respond so quickly and energetically that they can protect themselves against future attacks of the same bacteria. Or, as I expressed it in the article referred to, acquired immunity is due to a cell-function acquired during the intercellular contest between the cells and the invading bacteria.

While this increased cell-function is the prime factor in conferring on the animal immunity from subsequent attacks of the same disease, we must not fail to note the influence that chemical substances, retained in the body of an animal after an attack, may have in contributing to this result.

It is a fact well established by experimental research, that after certain of the acute infections[1] the body of the animal contains chemical substances that did not previously exist there, and which not only have the property of conferring immunity upon the animal in which they were developed, but also have a curative influence when injected into the body of another animal sick of the same disease. Not alone from these experiments, but from *à priori* facts, we conclude that after an attack of any of the self-limited parasitic diseases the body of the animal must contain a certain quantity of the chemical substance with which Nature (the cells) cured the disease, and this substance being present in a sufficient quantity to terminate the disease must be present in sufficient quantity to give present immunity. Retained chemical substances,[2] therefore, may confer immunity, but the immunity resulting from this cause will be more or less temporary, and will gradually disappear with the elimination of the chemical substances conferring the immunity, thus leaving the animal dependent on the cell-function spoken of for protection against future attacks of these diseases.

It is probable that this cell-function is called into action chiefly at the time when the tissues of the body are invaded by pathogenic bacteria, but it is also possible that under certain conditions, which we do not understand, this cell-function may be constantly exercised, producing the chemical germicides as rapidly as they are eliminated. The fact that the serum of the blood of certain animals that are naturally immune to a certain disease (for example, the rat to anthrax) has a bactericidal action on the germ of that disease, lends color to the belief that at least in natural immunity the cells of some animals may be constantly secreting the destroying germicide.

In order to avoid confusion and to better understand the relative importance of the two factors, cell-function and retained chemicals, which are

[1] For a review of this work the reader is referred to the paper of A. C. Abbott in THE MEDICAL NEWS, Nov. 7, 1891. Previously to the publication of Abbott's paper I had incorporated in this communication quotations from and references to recent experimental work that testify to the truth of this theory, but now in the interest of brevity and thoroughness I refer the reader to the paper referred to.

[1] See Abbott's paper, previously referred to.

[2] These substances act not alone as germicides, but also act by destroying the poisons produced by the "germs."

chiefly concerned in acquired immunity, we will study the question first in the general and then in the local parasitic diseases.

By *general parasitic diseases* we mean diseases such as tuberculosis, typhoid fever, measles, small-pox, etc., in which the bacteria causing the disease are not confined to any one part of the body, but are more or less generally distributed throughout the blood and tissues of the animal. Here the intercellular contest is a general one, and the cells in all parts of the body have their functional fighting-capacity alike developed. In this class of diseases the cell-function is the important factor in the after-immunity. The retained chemical germicides that are left in the body of the animal after an attack of the disease may of themselves be sufficient to explain complete temporary immunity, for a short time after the attack. But these substances will be gradually eliminated, and with their elimination the immunity that they confer will disappear. This will leave the animal in a comparatively short time protected against the disease *only* by the increased cell-function. The immunity resulting from this cell-function is more or less permanent, and is probably in some instances (in which one or both parents are immune) transmitted to the offspring. In this way, by natural selection, we may explain the origin of natural or inherited immunity. If immunity is, as we believe, dependent on the development of the functional fighting-capacity of the cells, then it would appear that a mild attack of one of the infections might only partially develop the cell-function, and therefore confer only partial immunity, leaving the animal yet susceptible to mild attacks of the same disease. Even though this be true, it would not follow that mild attacks of the acute infections always confer only partial immunity. This would follow if the difference in the severity of the attacks of these diseases always depended on a difference in the virulence of the contagion causing the disease; then the microbe with weak functional capacity for producing chemical poisons would be so easily destroyed by the cells that the cell-function of producing chemical germicides would be but feebly developed, and the animal, therefore, only partially protected against more virulent forms of the same disease. Protective inoculation with attenuated virus can, therefore, only give a partial protection against the more virulent forms of the same virus. This proposition, which is a logical conclusion from the foregoing argument, is amply supported by experimental investigation, which has shown that virus of increasing potencies must be injected into the body of an animal to confer complete immunity.

But, in the study of this difficult subject, we must remember that mild attacks are not always due to an attenuated virus. They are, probably, more often due to a partial natural immunity dependent on an inherited or natural cell-function that enables the cells very quickly to terminate the disease. The susceptibility of different animals to disease, therefore, depends on the degree of this inherited cell-function. If the function is highly developed, the animal is immune; if feebly developed, the animal is very susceptible to the disease. A mild attack of one of the acute infections may increase the development of this cell-function to such a degree as to give complete immunity. For this reason, when mild attacks are due to a lessened susceptibility, and not to a weakened virus, they may confer complete immunity. But the completeness of the immunity resulting in animals of like susceptibility, will be in direct proportion to the severity of the constitutional symptoms of the attack that conferred the immunity.

In the *local parasitic diseases* the mechanism of immunity is not altogether the same as in the general parasitic diseases. By local parasitic diseases we mean such diseases as erysipelas, diphtheria, and pneumonia. The bacteria causing diseases of this class are not generally distributed through the blood and tissues of the animal, but are confined to one or more parts of the body, where they produce their characteristic poisons, which are carried by the bloodvessels and lymphatics to all parts of the body, in this way producing constitutional symptoms. Local parasitic diseases are self-limited, but not in the same sense that constitutional parasitic diseases are limited. For example, the life of the diphtheritic inflammation is about three or four days; after this time the membrane is dead, and the disease has terminated at that point; but it may spread to other points, as from tonsil to tonsil, and then to pharynx, nose, or larynx, in this way continuing the disease indefinitely. But it, nevertheless, has a definite course, and confers on the mucous membrane involved at least temporary immunity.

The intercellular contest in local diseases is confined more or less to the part affected. Cells in distant parts of the body are not stimulated to the same functional activity as are the cells of the part affected, and, therefore, do not acquire the same power to resist future attacks of the same bacteria as do the cells at the site of the contest. In such a contest only a small minority of the cells of the body have their functional fighting-capacity fully developed, and these are the cells that take part in the hand-to-hand conflict. The cells in other parts of the body have this function much more feebly developed. We have, therefore, a few cells that have the power of conferring complete, and a great many cells that have the power of conferring

partial immunity. This would all be very well if the cells conferring complete immunity always stood guard at the portals through which the germs usually enter, but such is not the case. The cells taking the most active part in the contest are phagocytes. These cells, after the fight is over, find their way through the lymphatics and bloodvessels to all parts of the body, thus leaving the animal, as far as the functional fighting-capacity of the cell is concerned, only partially protected. But the other factor, viz., retained chemical products, is, in the local diseases, of prime importance. After the conflict is over, the body must contain a considerable quantity of the chemical substance manufactured by the cells for destroying the bacteria, and the amount of this substance present would depend on the severity of the constitutional symptoms of the attack in which it was produced. A local disease, with severe constitutional symptoms, might, therefore, leave the body so saturated with the proper chemical germicide as to give complete immunity. The completeness of the immunity will here again be in direct proportion to the constitutional symptoms of the attack that conferred it.

It is evident that immunity conferred in this way will slowly disappear with the elimination of the chemical substances on which it depends, until after a time there remains only the partial protection afforded by the feebly developed cell-function described. But the protection afforded by this partially developed cell-function will probably explain why second and third attacks of the local parasitic diseases are usually less severe than the primary attack, even though a long interval of time has intervened.

In this paper I have tried to give my reasons for believing the following propositions:

1. All self-limited parasitic diseases confer immunity.

2. In the local parasitic diseases, the completeness of the immunity, and the length of the period of immunity, will be in direct proportion to the severity of the constitutional symptoms of the attack that conferred the immunity. In this class of diseases, retained chemical products produced by the cells are the chief factors in conferring the immunity.

3. In the general parasitic diseases *in animals of like susceptibility*, the completeness of the immunity and the length of the period of immunity will be in direct proportion to the severity of the attack that conferred the immunity. In this class of diseases, acquired cell-function is the chief factor in conferring the immunity. Immunity from this cause is more or less lasting.

If the mechanism of immunity as here presented be correct, we have an insight into the method by which Nature cures and protects from future attacks of the parasitic diseases. In imitating Nature, experimental clinical medicine has a promising field opened for original work.

In the cure and prevention of disease the experimenter may use one of two substances:

1. The chemical substances produced by the cells.

2. The chemical substances produced by the bacteria.

Let us first note what results we may expect from the use of the chemical substances produced by the cells in curing the disease.

(*a*) By injecting these substances in sufficient quantity into the body of a healthy animal we would expect to confer complete temporary immunity to the particular bacterium that induced its formation. But this immunity would gradually disappear with the excretion of the cause on which it depended.

(*b*) By injecting this substance in sufficient quantities into the body of an animal sick of the disease, we would expect it to act as a true specific in the cure of the disease.

If, therefore, we could obtain these various chemical substances with which Nature cures the self-limited diseases, and with which she confers a temporary immunity against them, we would have the means not only of curing, but of preventing these diseases. These conclusions as to the therapeutic value of the chemical substances left in the body of an animal after an attack of a self-limited disease are logical inferences from the theory of immunity as presented; and the fact that these conclusions are proved to be true by the recent experiments of Emmerich, and Behring and Kitasato, is strong testimony to the accuracy of the theory that gave origin to these conclusions.

In the second place, let us note what beneficial results may be expected from the introduction of the products of the bacteria. As we have said, it matters not, so far as this argument is concerned, whether these substances act directly as chemical poisons or indirectly as enzymes producing toxalbumins. In either case it is clear that they can have no directly curative result in an animal sick of the disease; nor can they have any direct action in conferring immunity when injected into healthy animals. Whatever action they may have in either instance must, in accordance with the theory outlined, be an indirect one, and dependent on the power that these substances have of exciting the cells to the production of the substances that either destroy bacteria or neutralize their products, and thus terminate the disease and confer immunity. The disease is here terminated, and immunity conferred, not by the products of the bacteria, but by the products of the cells, in the same manner as when the cellular, instead of the bacterial, products were

introduced. The only difference is that, in the first instance, the cellular products are formed in the body of one animal, and introduced as a curative or prophylactic agent into the body of another animal, and whatever action they may have would disappear with their elimination. In the second instance, the cellular products are formed in the body of the animal experimented on, and by reason of this fact the animal would have this cell-function more fully developed. This, as we have already explained, would confer a more lasting immunity. By the injection of bacterial products in animals capable of resisting the disease, we may, therefore, expect to confer a more or less lasting immunity.

What may we expect from bacterial products as curative agents? From what has been said it is evident that bacterial products can in no sense be considered as curative agents. They are the cause of the disease, and not of the cure. While this is true, it may also be true that the presence of a large quantity of bacterial products in the body of an animal may cause the cells of that animal the more quickly to produce the counteracting cellular products that terminate the disease and confer immunity. We may, therefore, hope to hasten the termination of a *self-limited* disease by the careful injection of the bacterial products of that disease. But it is a nice question whether this is ever justifiable, even in the treatment of self-limited diseases.

In such diseases, by introducing the chemical weapons that are being used by the bacteria in their fight, we hope the more quickly to stimulate the cells to the production of the proper substances in sufficient quantity to more rapidly terminate the disease. In this method there is the evident danger of introducing too great a quantity of the bacterial products. Should we do this, instead of stimulating the cells to activity, we would paralyze their function and give the victory to the bacteria.

By injecting bacterial products, even in the self-limited diseases, we sacrifice the certainty to the rapidity of the cure. And in diseases *not* self-limited we hasten the fatal termination of the disease.

To show that the foregoing theoretic considerations have an important practical bearing, before closing my paper let me note the fact that they offer a most satisfactory explanation of the variable results that have been obtained by the treatment of tuberculosis with tuberculin, and that they may assist us in selecting the proper cases for this treatment.

Tuberculosis is in many instances, with good food and hygiene, and under favorable climatic surroundings, a self-limited disease, and it is only in such cases that the use of tuberculin would be permissible. Here, while it would have no direct curative effect on the disease, it would hasten the process by which Nature cures the disease. But in cases *not* self-limited it can only hasten the process that brings a fatal termination. The responsibility of using tuberculin is, therefore, a very great one, since the agent should never be used unless we are quite sure, from the family history, the general condition of the patient, and his hygienic and climatic surroundings, that the disease in this particular instance will be self-limited.

THE USES OF FEVER. THE DANGERS OF ANTIPYRETICS IN TYPHOID FEVER.[1]

By J. H. MUSSER, M.D.,
of Philadelphia.

Animal heat serves a physiologic purpose in the economy. When this degree of heat is beyond the limits of the norm its purposes are not physiologic. In health, normal heat is a stimulus essential to the carrying on of physiologic processes. Without it the nerve-centers controlling respiration, circulation, and other processes are dormant. No stretching of the imagination is necessary to conceive of such an impairment of the vital forces in consequence of which increased heat or fever is essential as a stimulus to enfeebled nerve-centers.

The following observation impressed the writer with the use of fever as a vital stimulant:

The patient, two years old, was ill of whooping-cough and its graver pulmonary complications—capillary bronchitis and atelectasis. Exhaustion was extreme, on account of her long illness of three months. Fever was marked. During the last week of her illness death was daily, then hourly expected. The hands and feet became cold, the face pale, the respirations excessively rapid and feeble (from 100 to 110), the pulse feeble and irregular and so rapid that it scarcely could be counted; a cold sweat bathed the brow, while stupor was present. These grave symptoms were first observed in the mornings. The temperature ranged between 100° and 101° at this time. As the day advanced, the usual afternoon exacerbation of fever took place. With such degree of heat came evidences of renewed strength. The extremities warmed, the color brightened, the respirations were less labored, the pulse became perceptibly stronger and fuller and more regular; intelligence was restored; though refused before, food was now taken with avidity, and even asked for, and notice taken of objects and events. Hope was restored, to fall again with each degree of decline of the thermometer.

These paroxysms of heat-exacerbation and stimulation at first took place daily. On the last three days of the child's illness, as recorded by the thermometer, they took place every two or three hours. Indeed, during the period of lowered temperature, so depressed and feeble was the child that death was momentarily looked for. As the temperature rose—but not until it was above normal for some time—the grave symptoms disappeared. These hourly

[1] Read before the College of Physicians, February 3, 1892.

heat-paroxysms were closely watched, and to no other cause than the stimulus of heat could the revivals of strength and increased functional activity of the circulatory and respiratory apparatus be attributed. It was difficult to picture, and was certainly a most striking exhibition of the play of heat-centers in the phenomena of life. Finally, the heat-centers did not respond to the unknown stimuli, after the stage of exhaustion they had undergone, the temperature did not rise, and gradually all function ceased.

I wished more particularly to place this observation on record in order that we should bear in mind in these times, when so much is said about the use of antipyretics, the dangers of fever, and the necessity of reducing temperature, that at certain times high temperature may have a physiologic use in the economy. I am well aware that certain German and French writers have held that high temperature is a conservative process, particularly in septic conditions, through its effect upon the bacteria or the poisons generated by them. But, independently of this action, fever serves quite a physiologic use in the economy. This is the only observation that I wish to record in regard to the use of fever.

The following remarks are addressed to practitioners who continue to use, and think they must use, antipyretic medicines, because the thermometer records high temperatures. I have never used such means to reduce temperature in typhoid fever, but I wish to particularly impress upon those who will use antifebrile drugs that it is at times essential they should withhold their hands. The present intemperance in the use of antipyretics is due to laudation in the past of this class of drugs by eminent therapeutists.

Now, in regard to the danger of the use of antipyretics in certain cases of typhoid fever. There are three periods in the course of typhoid fever when, without doubt, the use of antipyretics is dangerous, and these must be carefully considered: First, in the early or middle period of cases that come to us after removal from a distance. Sir William Jenner was the first to lay great stress upon the danger of the removal of a patient suffering with typhoid fever. Anyone that observes cases in the medical ward of a hospital will notice that the temperature for the first twenty-four hours after admission is unusually high—that is, higher than one would expect at the period that the disease has reached. This rise of temperature is undoubtedly due to the exhaustion that has taken place on account of the removal to the institution. I have seen this so often and made so many observations in connection with it that I hesitate to use any antipyretic during the first twenty-four hours after admission. The records that I have bear out the correctness of this course. Even if no antipyretic is given, the temperature usually falls to the proper point in twenty-four hours. Sometimes stimulants are required, and under their use the temperature falls. On the other hand, I have seen cases admitted with a temperature of 105° or 105.5°, in which an antipyretic was given with serious results. I am so sure of the inadvisability of administering an antipyretic under these circumstances that I direct that no antipyretic be given during the first twenty-four hours after admission, but that stimulants shall be administered.

Again, there are certain cases in which peculiar idiosyncrasies exist, in which it is inadmissible to use antipyretics during the course of typhoid fever, no matter how high the temperature may be, if life is not threatened. I remember one such case among a number of others. We have all seen patients that were particularly susceptible to drugs, to the application of external cold, to any kind of stimulant, and to opiates or alcohol in any form. The case that I have in mind is that of a young woman who was in the private ward of the Presbyterian Hospital, with typhoid fever running a regular course, but with excessively high temperature. It was impossible to administer any antipyretic. She was extraordinarily susceptible to quinine, one grain producing serious nervous symptoms. The use of alcohol caused increased headache and violent nervous symptoms. The external application of cold and the external use of alcohol or other refrigerants produced shivering and great depression. Without my concurrence, five grains of antipyrin on one occasion were administered with such serious collapse that for five hours it required the efforts of three of the *internes* to restore the patient to her natural temperature, and, in fact, to save her life. It was the most extraordinary degree of depression that I have seen from a single administration of the drug. This is an example of a number of cases in which it is impossible to administer antipyretics, as a result of peculiarities of individual constitution. I think that physicians who are constantly calling attention to the use of antipyretics neglect to look for these peculiarities, which I think are present in many cases. I have now under observation an individual of highly nervous temperament, to whom I would not administer an antipyretic unless life was absolutely threatened.

It is in the latter stages of typhoid fever that I think antipyretics are especially dangerous, and must be administered with the greatest care. Two classes of such cases are worthy of attention. There is one class in which the temperature persistently remains at the maximum, but there is abatement of all of the other symptoms—lessening of the diarrhea, cleaning of the tongue, diminution of the delirium, and even lowering of the pulse, with in-

crease of strength. We feel that the typhoid process is ended, but the fever, nevertheless, continues high. I will illustrate this with brief reports of two cases:

In the first case, in a lad ten years of age, whom I attended during the course of an attack of typhoid fever, from the fifteenth to the eighteenth day of the disease the temperature ranged between 104° and 105.5°. The tongue had cleaned, the number of stools had lessened and these were gradually becoming formed, and I felt that the pathologic process was at an end, and that if we waited a little while the fever would probably subside. There were no dangerous symptoms except the high fever. At 10 o'clock on the evening of the eighteenth day the temperature was 105°; it then began to fall until, at 6 o'clock in the morning, it was just below 96°; it required all the efforts of the father and the nurse to prevent what they thought to be a fatal collapse. The temperature remained below 96° for an hour, then began to rise, and by 9 o'clock in the evening it was 104°. It remained at about this point for two hours, and then gradually fell until in the morning it was 96.5°. It then rose again, to be followed by another fall, but not to such a low point. There is no way in which this fall in temperature could have been anticipated. If we had applied external cold or administered an internal antipyretic, I am quite sure that the collapse that occurred naturally would have been a fatal one. This sudden fall often occurs in typhoid fever in children, and it is one of the ways in which the fever subsides, the disease terminating by crisis.

In the second case—that of a young man, seventeen years of age, who was treated in the private wards of the University Hospital a year ago, and who had a prolonged and severe attack of typhoid fever, the temperature keeping high—without warning or cause a "nervous chill" occurred, followed by a fall in the temperature from 104.4° to 95.5°, the thermometer rising again to its former level. The temperature kept thus for five or six days, and then gradually fell. I know of no way in which the fall of temperature could have been anticipated. Before it occurred we were much tempted to use some active means to reduce the temperature, but, had this been done, it might have been serious for the patient.

I recently treated with turpentine, in the Presbyterian Hospital, a case of typhoid fever in a man twenty-six years of age, in whom the disease ran a perfectly normal course. While grave, the symptoms were not alarming, and the temperature ranged between 103° and 104°. At one of my visits I found a falling temperature, which continued until the mercury registered 96.5°, being followed by a gradual rise, with a subsequent decline by lysis. This is another case in which no one could have anticipated the fall of temperature, which, I am sure, was a part of the disease, and not due to any cause that would produce collapse.

These three cases are examples that I have taken at random from an abundance of typhoid fever notes, in which the administration of an antipyretic in the latter stages of the disease would have been dangerous.

Of course, there is still another class of cases in which it would be dangerous to administer an antipyretic, those, viz., to which Dr. Da Costa has particularly called attention, in which the morbid process has terminated, but—on account of the exhaustion, or the long continuance in bed, or the limited diet—the temperature keeps up, or even begins to rise. Such a case was under my care last year. These have been spoken of as cases of bed-fever, and in such instances the administration of an antipyretic would not have the desired result. In these cases the fever is due to exhaustion, lack of food, and long continuance in bed. The use of stimulants, solid food, and getting the patient out of bed, bring back the temperature to the normal.

The foregoing are the classes of cases to which I wished particularly to call attention in connection with the dangers of antipyretics in typhoid fever. The attention of the College is invited as much for criticism as for discussion, and, finally, in order to say that if physicians will give antipyretics in typhoid fever, it behooves them not to administer them in the cases or under the conditions related.

DIPHTHERIA AND ITS TREATMENT.

By ALEXANDER FULTON, M.D.,
of Philadelphia.

The coccus insect, a miniature creature, feeds particularly on one plant, the nopal; the potato-bug on the potato-vine; the rose-beetle on the rose-vine, etc. These parasites suddenly and mysteriously appear and disappear; are very destructive to the plant; only starvation will make them infest other plants; and, owing to great powers of multiplication, the means must be prompt and efficient to kill them. So it is with the diphtheritic bacterium. It has an especial affinity for the tonsils. Its presence on these organs is the local manifestation that chiefly characterizes diphtheria. If not early and thoroughly destroyed, it will multiply and extend its ravages with wonderful rapidity and injury.

The subjoined treatment is based upon this theory, and has been successful in thirty-seven consecutive cases, this number being all of the cases in which I used it. It consists in the application to the patches of a strong solution of argentic nitrate, ℈j to f℥ss of rose-water, by means of a throat-brush, so constructed that it will not break, etc. I wish to emphasize that this application must be repeated at one sitting sufficiently to remove the patches or to saturate them. Failure in this respect may cost the life of the patient.

In the early stages of the disease the patches can

almost invariably be wiped off with one sweep of the brush, which is not the case later on, when they become deeply adherent. These applications should be made twice a day, morning and night, but may be used according to the exigencies of the case, or so long as the deposits are observed, since they show a tendency to reappear. Often after one effectual cleansing of the throat in this way the patches do not return, and there is a subsidence of all of the symptoms of the disease. The agent must be kept in a blue bottle excluded from the light, and the brush or whatever instrument is used in making the application should be washed and kept in an antiseptic solution.

If practicable, the foregoing procedure should be immediately followed by a gargle, such, *e.g.*, as the following:

℞.—Tinct. kino . . . . f℥ij.
Glycerin . . . . . f℥ij.
Ol. eucalyptol . . . . gtt. x.—M.
S.—A teaspoonful in a tablespoonful of water as a gargle.

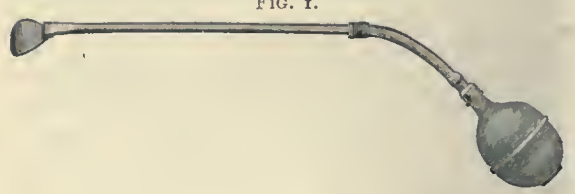
The operator may wear gloves to prevent discoloration of the hands by the silver, and the face should also be guarded from the stain.

Whether or not the gargle be used, the throat should be dusted with the following:

℞.—Hydrarg. chlor. corros. . . gr. j.
Pulv. sulphuris . . . . ℥j.—M.
S.—Blow a pinch into the throat every four hours.

For this purpose, I use an insufflator, shown in the annexed engraving. A pinch of the powder

FIG. 1.



component of the treatment is pressed into the tube as it opens above the tongue-depressor attachment. Thus charged, it is used as an ordinary tongue-depressor, when, upon the desired exposure of the part to be treated, compression of the rubber ball expels the powder in an effective and reliable manner. It may be necessary to discontinue the use of this mercurial combination in a day or two. Its administration must be under the supervision of the physician, on account of the possible systemic toxic action, although I have not experienced any such unpleasant occurrence.

In connection with this treatment I give from the commencement, according to the age of the patient:

℞.—Pulv. potas. chlorat. . . ℥ij.
Tinct. ferri chlor. . . . f℥ij.
Syr. limonis . . . . f℥iij.
Ol. gaultheriæ . . . . gtt. iij.—M.
S.—A teaspoonful every two or three hours.

I also apply externally, over the site of the tonsil:

℞.—Tinct. iodi. . . . . f℥ij.
Ol. camphorat. . . . . f℥j.—M.
S.—Apply every four hours.

This is best done by wetting a piece of flannel with the remedy and holding it in place by means of a roller bandage.

I have always found this procedure to reduce the external swelling. Care must be exercised so as not to soil the clothing.

When there is a rise of temperature, indicating the need of antipyretics, I resort to small doses of antipyrin and withhold its use upon a sufficient diminution of temperature. During convalescence I advise the use of mist. ferri et ammon. acetatis, light nutritious diet, and champagne.

Sometimes the stomach is so irritable that it rejects everything given. This condition is generally alleviated by giving the wine.

In only a few cases were there noteworthy sequelæ, from which the patients ultimately recovered.

Perhaps in my cases the reality of the disease may be doubted, but the adoption of the treatment will convince the most skeptical. However, the accompanying drawing represents the membrane as removed in almost every one of my cases.

FIG. 2.

Furthermore, albumin was almost always present in the urine. Sometimes angina coëxisted.

The mortality and gravity being large, it seems that the treatment of diphtheria may be susceptible of much improvement. Anything that has been proved useful in so large a number of cases as I report is certainly worth a trial.

Alumni Association of Jefferson Medical College.—Dr. Jerome K. Bauday, of St. Louis, will deliver the annual oration before the Alumni Association of Jefferson Medical College on Monday evening, April 25, 1892, at 8 o'clock, in the amphitheater of Jefferson Hospital, after which a dinner will be tendered him at the Hotel Stratford.

RECENT ADDITIONS TO THE MATERIA MEDICA.

By W. A. N. DORLAND, M.D.,
INSTRUCTOR IN GYNECOLOGY, PHILADELPHIA POLYCLINIC.

(Concluded from page 427.)

Methacetin, $C_6H_4.OCH_3.NH.C_2H_3O$. Para-acetanilidin or oxy-methyl-acetanilid, is a derivative of amidophenol. It occurs as a slightly reddish crystalline powder, odorless, of a faintly bitter, saline taste, soluble in warm water but less so in cold, very soluble in alcohol and glycerin, melting at 248° F. It resembles antipyrin in action, and the effects ensue rapidly on account of the drug's solubility. The fall of temperature is gradual, lasting some hours, and followed by a rise. Methacetin is best administered in pulmonary tuberculosis between three and four in the afternoon. The fall in temperature is accompanied by profuse sweating, and occasionally the drug exerts an unfavorable influence upon the heart, slight collapse following the exhibition of 7 grains. Seidler found that it acted well in acute and subacute rheumatism, mitigating the pain, fever, and swelling. It is, however, less efficacious as an antineuralgic. *Dose*—from 2 to 4 grains, exhibited with great caution. *Antipyretic, antineuralgic.*

Microcidin. Sodium naphtholate, a combination of naphthol and caustic soda, occurs as a tasteless, odorless, white powder, very soluble in water, giving in concentrated solution a brown color; it has no caustic properties and is but slightly toxic; it is antipyretic, and is excreted in large quantities by the kidneys. It is superior to phenic and boric acids as an antiseptic, but inferior to naphthol and corrosive sublimate. Solutions of from 3 to 5 : 1000 answer every purpose. Under its influence leg-ulcers and suppurating wounds cicatrize rapidly, and the odor of gangrenous wounds is quickly neutralized. For infected wounds a 5 : 1000 solution is needed, but a 3 : 1000 solution is sufficient to guard wounds from infection. Berlioz places microcidin among the best and most innocuous *antiseptics.*

Orexin, $C_{14}H_{12}N_2.HCl.2H_2O$. Phenyl-dihydro-chinolin hydrochlorate, is a yellowish-white crystalline powder with a nauseous pungent taste; insoluble in ether, soluble in water and alcohol. It has the property of stimulating the gastric secretion and thus of increasing the appetite. Penzoldt has had great success with it in anorexia not due to or complicated with gastric disease proper; it is only to be used in anorexia when this condition is a secondary symptom. He has employed it after major operations, in pulmonary tuberculosis, chlorosis, pleuritic exudations, pulmonary emphysema, heart-affections, various anemic conditions, and in defective nutrition generally. Its use is counter-indicated by the existence of any gastric disease proper (on account of its irritating action on the mucous membrane), in advanced pernicious constitutional disease, or when there is preëxisting hyperacidity due to HCl. It has given good results in chronic gastric catarrhs other than those of congestive origin and those due to alcoholism. Gordon has used it as an appetizer and stomachic in children, with satisfaction. *Dose*—from 2 to 5 grains in gelatin-coated pills, powder, or wafers during meals, with copious draughts of milk or beef-tea, to prevent any possible gastric irritation. *Stomachic.*

Ouabain, $C_{30}H_{46}O_{12}+7H_2O$, is a glucoside obtained by crystallization from a watery extract of the roots of Ouabaio, *Carissa Schimperi*, a member of the important family of apocynaceæ. It appears in rectangular scales, excessively thin and of a pearly aspect, odorless, and without appreciable bitterness; it is slightly soluble in cold, and very soluble in boiling water and moderately concentrated alcohol; insoluble in chloroform, anhydrous ether and absolute alcohol; it melts at 200° C., and is violently poisonous. It is probably homologous with strophanthin, which it closly resembles in its action, being, however, more toxic. The toxic effects are considerable slowing of the pulse and respiration, the latter of which is especially to be guarded against. It has been found very efficacious in whooping-cough. It promotes the action of the skin after three or four days' treatment, and also increases the flow of urine, and diminishes the quantity of sugar that may be present. It action is not cumulative. Applied to the eye it produces corneal anesthesia, but is inferior to cocaine. *Dose*—from $\frac{1}{2000}$ to $\frac{1}{250}$ grain given as a per mille solution; according to Gemmell, the standard dose for a child under five years is $\frac{1}{1000}$ grain every three hours in solution. *Diuretic.*

Pambotano is a Mexican plant, *Calliandra Houstoni*, belonging to the order of leguminacæ. It is a bitter of the first order, of great value in marsh fevers, typhoid fever, influenza, and tuberculosis. Usually one dose is sufficient to cure periodic attacks. *Dose*—70 grains in twenty-four hours to an adult, administered in four equal portions in hot sweetened water or tea. The preparations are the tincture, decoction, and alcoholic elixir. *Antimalarial.*

Papain is a ferment obtained from the milky juice of *Carica papaya*, a South American fruit tree of the natural order papayaceæ; it is prepared by mixing the juice with alcohol. It occurs as an amorphous yellowish-white powder, odorless, almost tasteless; soluble in water, but not in alcohol. Its composition has not yet been determined, but it contains 10.6 per cent. of nitrogen. It possesses active digestive powers, but differs from pepsin in the fact that it softens and dissolves fibrin in liquids that may be either acid, neutral, or slightly alkaline. It also acts at higher temperatures and more rapidly than pepsin. It is the best solvent known for diphtheritic membrane, and, according to Baginsky, should be dabbed on, to avoid irritation of the affected area; a 5 per cent. solution should be used for this purpose, or as a spray. The following prescription of Dr. W. C. Caldwell has obtained special popularity in diphtheria: Papain, 2 drams; hydronaphthol, 3 grains; hydrochloric acid, 15 drops; distilled water, q. s. ad 4 drams; to be applied to the membrane with a camel's-hair brush. One of the principal fields of usefulness for papain is the expulsion of intestinal parasites; it destroys or digests the parasites, after which a laxative is required to expel them. For tape-worm, from 3 to 10 grains are mixed with 4 grains of Dover's powder, and one-sixth taken night and morning. It is said to have a solvent effect when applied to indurated carcinomatous tissue, and, so used, has yielded good results in the hands of competent observers. A 5 per cent. solution with a 2½ per cent. solution of sodium bicarbonate has been recommended for cleansing the middle ear in chronic suppuration, 15 minims being

dropped into the meatus. A solution containing 12 grains of papain, 5 grains of borax, and 2 drams of water, painted on the hands twice a day will remove the warts in chronic eczema and hypertrophied conditions of the palms of the hands. A solution in glycerin is useful for ulcers and fissures of the tongue. *Dose*—from 1 to 10 grains, best administered alone. The elixir of papain may be used in dyspepsia and sea-sickness in 1 dram doses. *Digestant.*

PARACRESOTIC ACID, $C_8H_9O_3$, is prepared from paracresylol by the action of carbonic acid in the presence of sodium. It crystallizes from water in long, white, brilliant needles, slightly soluble in cold water, and more so in warm water, alcohol, ether, and chloroform; it melts at 151° F. It is employed mostly in the form of *sodium paracresotate*, $C_8H_7NaO_3$, a very fine crystalline powder, of bitter but not disagreeable or nauseating taste, soluble one part in twenty-four of water. Its action is very similar to that of sodium salicylate, and it has found special application for administration to children. It is a safe and reliable antipyretic. It is eliminated in part as pure paracresotic acid, and partly as that acid associated with gylcosuric acid. It has antiseptic properties as powerful as those of salicylic acid. Demme largely used it as an antipyretic and antizymotic in children with acute articular rheumatism, in which, though inferior to salicylic acid as an antipyretic, it did not provoke as grave troubles. It is well tolerated by the digestive organs. It exerts a favorable influence upon the course of catarrhal pneumonia. In the gastro-intestinal catarrh of nurslings it gives results analogous to those of resorcin. For this purpose Demme used the following prescription: Sodium paracresotate, from grains 1½ to 3; tincture of opium, from drops 2 to 4; cognac, minims 15; syrup of acacia, dram 1; distilled water, drams 6½. Of this a dram was given every two hours. *Dose*—from 2 to 3 grains in a one-ounce mixture, a teaspoonful of which is given every two hours (for children); larger doses (up to 2 drams of the salt) may be safely given to adults. *Antipyretic.*

PENTAL, C_5H_{10}. Trimethylethylene, produced by heating amylen hydrate in the presence of acids, is said by v. Mering to be a safe and effective anesthetic. It is a colorless liquid of low specific gravity, boiling at 100.4° F., and burning with a luminous flame; it is insoluble in water; exceedingly volatile; but does not decompose on exposure to air or light. It is readily inhaled, without affecting the membranes of the throat or air-passages. From 10 to 25 cc. suffice to anesthetize, the narcosis coming on gradually, without any preceding symptoms, without any influence on respiration or heart-action, and with no unpleasant after-effects. Although sensibility is absent, consciousness is partially preserved, and in deepest narcosis patients open the mouth and jaws when directed to do so. Awakening is quite gradual. The agent is best administered by means of Junker's inhaler, which modifies the unpleasant odor of the fluid. *Anesthetic.*

PHENOCOLL, $C_6H_4{<}^{OC_2H_5}_{NH-OC.CH_2-NH_2}$. Phenolglycocoll, or amido-acet-para-phenetidin, occurs in white, acicular crystals, with a tendency to mat themselves together; it is slightly soluble in ether, benzol, chloroform, and cold water, freely so in alcohol and warm water. *Phenocoll hydrochlorate* is a white, microcrystalline powder, soluble in sixteen parts of cold water the solution being of neutral reaction; it has an unpleasant bitter and saline taste. Phenocoll kills by an action upon the respiratory center, but does not affect the composition of the blood. Its antipyretic action is rapid and powerful, but the effect upon the temperature is of but short duration. Phenocoll is especially efficacious in fever of hectic type, and is a superior antipyretic in typhoid fever and pneumonia. It does not produce collapse or cyanosis, and gives rise to but slight sweating. It is rapidly eliminated, and seems to exert no injurious effect upon the kidneys. It is a valuable nervine, and answers well as an antirheumatic in chronic rheumatic affections, as well as in the acute affections and in sciatica; it has no effect, however, in gonorrheal rheumatism (Hertel). It has been successfully employed in influenza. In pulmonary tuberculosis, it has been used subcutaneously with advantage. *Dose*—of the hydrochlorate, from 8 to 15 grains; repeated at intervals of about one hour. It is preferably administered at bed-time, as the action of the drug is heightened during the complete rest of the night's sleep. *Antipyretic, analgesic, nervine.*

PIPERAZIN, $C_4H_{10}N_2$, is a piperidin in which the CH_2 group has been replaced by the NH. It occurs in well-defined acicular colorless crystals, readily soluble in water and strongly alkaline in solution, with no toxic properties. It is particularly designed to take the place of the lithium salts, and has proven itself of great service in the management of the uric-acid diathesis, with the formation of concretions in the kidneys. In this condition, tablespoonful doses of the ½ per cent. solution are employed; the drug hastens the elimination of the renal calculi and arrests the severe colic-like paroxysms. Undoubtedly piperazin possesses unusually great uric-acid solvent power, and its general applicability in gout, rheumatism, urinary calculus, and all diseases consequent upon the uric-acid diathesis is evident. Its great advantage over lithium is that it will form seven times more of a combined salt with the uric acid than will lithium, and the resultant piperazin urate is twelve times more soluble than the lithium urate. The following mixture has been recommended for solvent purposes: Piperazini puri, grains 15; syr. cort. aurant., drams 6; aqua destil., q. s. ad ounces 6; to be taken during the day. In lumbago, subcutaneous injections of a 2 per cent. solution were employed, with entire relief from the pain in nine or ten days; the injections themselves were quite painful, but no abscesses or unpleasant after-effects were noted. Piperazin has been used in mental troubles and in lead paralysis as a tonic and diuretic, and has been recommended in pruritus and nocturnal enuresis. *Dose*—from 5 to 8 grains several times daily, with a maximum of from 15 to 30 grains; subcutaneously, 5 grains. The best mode of administration is as follows: Dissolve 15 grains of pure piperazin in about one quart of carbonated water, and direct the patient to drink this amount in convenient doses in the day. By adding 15 grains of phenocoll hydrochlorate an additional analgesic action is secured. *Piperazin water*, thus prepared, may be bought in one quart mineral-water bottles. *Uric-acid solvent.*

PYOKTANIN, or *methyl-violet*, appears in two varieties, *blue* for surgical, and *yellow* for ophthalmic purposes. Both are made into dusting powder (2 per cent.), oint-

ment (2 per cent.), and gauze (1 : 1000). The stains produced by pyoktanin upon the skin may be removed by alcohol. Pyoktanin possesses antiseptic properties to a marked degree, and when injected into the tissues diffuses itself at once. By its action on the nuclei of cells of neoplastic growths pyoktanin renders them sterile. Professor Ceccherelli arrested the growth of an enormous sarcoma of the lower jaw by means of parenchymatous injections of from ½ to 1 dram of a 1 : 300 solution, repeated every two or three days. Pyoktanin has also been used in epithelioma of the cheek, eyelid, and breast, and Boldt asserts that good results and possible cures follow its injection in uterine carcinoma, together with 4 grain doses internally daily. Bellotti has used it with success in the form of dressings of carbolized cotton-wool, saturated with a 1 per cent. solution of pyoktanin, in a rodent ulcer of twelve years' standing. The pain that is produced when it is dusted upon carcinomatous growths may be alleviated by the use of cocaine. In a ½ per cent. solution and in pencil form it is well borne by the eye, according to Marchetti. Especially is it of service in dacryocystitis, chronic blennorrhea, extensive corneal infiltrations, hypopyon-keratitis and panophthalmia. It has also been used in suppurating affections of the nasal cavity, and in injections of 1 to from 500 to 1000 twice daily in obstinate chronic cystitis. *Dose*—from 1 to 5 grains. *Antiseptic.*

Pyridin, C_5H_5N. A liquid alkaloid obtained in the destructive distillation of bones; it is colorless and mobile, with a powerful empyreumatic odor, boiling at 242° F., having a specific gravity of 0.985, and being freely miscible with water, alcohol, ether, and chloroform. It forms crystalline salts with acids. It is employed to relieve the dyspnea of asthma, and is believed to be the active agent in the various cigarettes recommended for that purpose. The vapor of a dram inhaled two or three times a day eases respiration and soon effects a cure. Pyridin has also been used in angina pectoris and cardiac failure. *Dose*—from 1 to 1½ drams by inhalation. *Anti-asthmatic.*

Salipyrin, $C_{11}H_{13}N_2O.C_7H_6O_3$, antipyrin salicylate, occurs in crystalline scales or in powder; it is odorless, of a pleasant acidulous taste, almost insoluble in water and ether, and freely soluble in alcohol. It may be given in all cases in which the combined action of antipyrin and salicylic acid is desired. It lowers the fever temperature of the body, and has pronounced analgesic action in cases of acute articular rheumatism, diminishing the tense and painful feeling in the affected joints, without producing the profuse perspiration seen after the use of salicylic acid. In rheumatic sciatica and in neuralgias of the face of rheumatic origin, its action is prompt. Hennig recommends it in influenza. *Dose*—from 15 to 30 grains at intervals of two, three, or four hours, until 90 grains are taken. It may be administered in capsule, wafers, or in solution, thus: Salipyrin, 1½ drams; glycerin, 3½ drams; syr. rub. id., 7½ drams; aqua destil., 10 drams. Of this a tablespoolful should be taken at a dose. *Analgesic, antipyretic.*

Salophen, $C_6H_4 <^{OH}_{COO.C_6H_4N} <^{H}_{CO.CH_3}$, a derivative of salicylic acid, containing 51 per cent. of the latter drug, occurs in the form of small crystalline plates, is white, odorless, tasteless, scarcely soluble in water, very soluble in alcohol and ether. In the body it is broken up into salicylic acid and acetylparamidophenol. When administered in acute articular rheumatism, the pains are rapidly dispelled and the swelling quickly disappears. It is not so prompt in alleviating the pains of chronic rheumatism; nor does it protect against relapse in the acute form, It has but a slight antipyretic action. *Dose*—from 60 to 90 grains daily. *Anti-rheumatic.*

Solutol, is a preparation containing in 100 c.c., 60.4 grams of cresol, of which one-fourth is free, and the other three-fourths in combination as sodium cresol. Solutol is miscible with water, forming a perfectly clear solution. It is claimed that solutol combines the disinfecting action of cresol and sodium hydrate. For the disinfecting of rooms, etc., an odorless, pure form is manufactured. It is generally used in 5 per cent. solution. For surgical disinfection a neutral solution of cresol in sodium-cresol is sold under the name of *solveol;* employed in ½ per cent. solution, it is less poisonous than a phenol solution of equal efficacy (from 2 to 3 or 5 per cent.). *Disinfectant.*

Sozoiodol, $C_6H_2(HSO_3)I_2.OH$, di-iodo-paraphenolsulphonic acid, is a combination of iodine (54 per cent.), carbolic acid (20 per cent.), and sulphur (7 per cent.). It has powerful antiseptic properties, and is recommended as an odorless substitute for iodoform, in syphilitic, tuberculous, and scrofulous ulcerations. On account of its insolubility, sodium and potassium-sozoiodol are specially recommended in affections of the respiratory organs, such as ozena and laryngitis, in the form of insufflations. Sozoiodol itself is very efficacious in tuberculous and scrofulous ulcerations and in affections of the generative organs, such as gonorrhea and syphilis. In leg ulcers and superficial burns Nitschmann advises the use of the following ointment: sodii sozoiodol, 1 dram; lanolin, 10 drams. *Antiseptic.*

Styracol, the cinnamate of guaiacol, has been introduced as a tasteless substitute for guaiacol. It has pronounced antiseptic properties, retards fermentation and decomposition, accelerates the healing of wounds and sores, and has marked therapeutic value when administered internally for catarrh of the bladder, gonorrhea, gastro-intestinal catarrh, etc. *Dose*—5 grains. *Antiseptic.*

Sulphaminol, thio-oxydiphenylamine, is obtained by the action of sulphur on the salts of methoxydiphenylamine. It is a pale-yellow, odorless, and tasteless powder, insoluble in water, soluble in alcohol, glacial acetic acid, and alkalies; it melts at 311° F.; is non-toxic, and has been used with success as a substitute for iodoform. In contact with the animal secretions it is said to split up into its components, sulphur and phenol. Its application is painless, and it appears to be an antisuppurative. It exerts a peculiar desiccating influence upon wounds, which heal rapidly under its influence. Especially is it of service in the after-treatment of nasal operative wounds in the form of insufflations, as well as in diseases of the antrum and frontal sinuses. *Antiseptic.*

Thermifugin, $C_9H_8(CH_3)NCOONa$, methyl-trihydro-oxyquinolin, or sodium carbamate, is a faint, yellowish-white, lustrous salt, forming a brown solution with water. Although it has not come into general use, it is recommended as an antipyretic, being said to combine

the three properties of reducing temperature, retarding the pulse, and increasing the blood-pressure. *Antipyretic.*

THILANIN is a sulphuretted lanolin, designed to replace ichthyol and thiol. It is a dark-brown ointment-like mass, having about the same consistence as lanolin, and a slight sulphurous odor, containing about 3 per cent. of sulphur. It can be readily mixed with liquids, whether oleaginous or aqueous, is absolutely non-irritating, and has a more energetic action than other remedies. It mitigates the itching in a number of skin-affections, and has been used successfully in all forms of eczema, wherever situated, in children and adults. Good results are reported in sycosis, acne, and other affections. *In dermatology.*

THIOL, or German ichthyol, an artificial representative of natural ichthyol, is prepared by heating gas-oil with sulphur. Thiol is met with in two forms: *dry*, in black or brownish scales, or in dark-brown powder with a feeble, bituminous odor and bitter astringent taste; and *liquid*, the latter containing about 40 per cent. of the former, which may be prepared from it by evaporation. An ointment of liquid thiol, 1 in 8, and a dusting powder of dry thiol 1, with starch 1, oxide of zinc 2, and talc 16, have been employed. Thiol is soluble in alcohol, ether, and water. Gottschalk has used it in inflammation of the uterus and its appendages; he has treated parametritic and perimetritic exudations with vaginal tampons impregnated with from a 10 to 20 per cent. glycerin solutions of the drug. A free flow of vaginal secretion is produced, and the tampon is removed in twenty-four hours. At the same time he rubs the abdomen with a salve of thiol. The pelvic exudates disappear in a few weeks. Inflammatory erosions about the vagina are treated successfully with dry thiol powder, while acute and chronic endometritis yield readily to the solution applied on an applicator. At times an exfoliation of the mucous membrane is produced. *Dose*—of dry thiol, from 2 to 10 grains. *In gynecology.*

THYMACETIN, $C_6H_2CH_3C_3H_7{<}^{OC_2H_5}_{NH(C_2H_3O)}$, is a derivative of thymol. It is a white crystalline powder, slightly soluble in water. Its therapeutic properties have not yet been thoroughly studied. In thirty-grain doses it does not produce toxic effects upon the dog. Jolly, of Berlin, has studied its action upon the nervous system of man. He finds that it arrests headaches, except migraine, which is but slightly affected by it. On the contrary, generalized cephalalgia, either paroxysmal or continuous, in the course of some other malady, yields readily to it. It failed in cephalalgia due to a cerebral lesion; and in a case of gastric crisis for a short time only it was substituted successfully for morphine. In some instances it has given rise to congestion of the head, and at times to somnolence. It has also, then, a soporific effect. *Dose*—from 3 to 15 grains. *Antineuralgic.*

TRICHLORACETIC ACID, $HC_2Cl_3O_2$, occurs in deliquescent colorless crystals. It is one of the best caustics in the materia medica, especially for rhino-pharyngology. It cannot be melted on a sound like silver nitrate or chromic acid; hence there is some difficulty in applying it. The best method of application is to wrap a tiny firm ball of cotton-wool round a fine-pointed sound and soak it with the liquefied acid. Whilst chromic acid causes violent pain during and after application, trichloracetic acid does not cause any unpleasant sensation until some seconds after it has been applied, and then the pain is quite transient, and may be entirely or very nearly annulled by cocainizing three or four times before the acid is applied. The parts of the mucous membrane treated with the acid become snow-white, and the action is localized and more persistent. Healing is free from pain or reaction, and is completed more quickly than when the electro-cautery is used. *Caustic.*

TUMENOL, a sulphonated preparation of hydrocarbon, may be used in three forms: 1. Tumenol itself—a dark-brown or brownish-black liquid; 2. Tumenol sulphone, an aromatic syrupy liquid; 3. Tumenol sulphonic acid, a black powder, bitter, odorless, soluble in water. It is especially recommended for the itching of eczema and other forms of dermatitis, prurigo, and pruritus, in the form of a 10 per cent. tincture, with a menstruum consisting of equal parts of ether, rectified spirits, glycerin, and water. It has not the penetrating anti-parasitic and absorption-promoting properties of ichthyol, and is, therefore, not of service in erysipelas or in the local treatment of exudation or infiltration in which ichthyol is so useful. Moist compresses soaked with from a 2 to 5 per cent. solution of the sulphonic acid are serviceable in the treatment of acute recurrent eczema of the hands and face. In the form of a paste, of from 5 to 10 per cent., tumenol oil proved more effective than the simple zinc paste, not only in eczema, but in superficial ulceration, impetigo, and pemphigus. *In dermatology.*

CLINICAL MEMORANDUM.

TWO FATAL CASES OF OBSTRUCTION OF THE COMMON BILE-DUCT.

BY AUGUSTUS A. ESHNER, M.D.,

INSTRUCTOR IN CLINICAL MEDICINE IN JEFFERSON MEDICAL COLLEGE AND IN THE PHILADELPHIA POLYCLINIC; REGISTRAR IN THE NEUROLOGICAL DEPARTMENT OF THE PHILADELPHIA HOSPITAL.

THE two cases that I herewith report are interesting because both of their unusual termination and the therapeutic lesson that they teach. They were seen at the Philadelphia Hospital in the ward of Dr. J. B. Walker, by whose kind permission this publication is made. By one of those strange coincidences so commonly encountered, the patients occupied adjoining beds, and died within a few days of one another.

It is not uncommon to find biliary calculi at autopsies in cases of death from various causes, but death as a result of occlusion of the common bile-duct in connection with cholelithiasis is not common, while death following acute occlusion is rare.

One of the cases involved a man, seventy-seven years old, of feeble intelligence, with emphysematous lungs, atheromatous vessels, and degenerate kidneys. All that could be learned was that the jaundice, which had existed for several months, had set in suddenly with vomiting. For a considerable time the man presented typical "hepatic intermittent" fever, with irregularly-recurring rigors, pyrexia, and sweats. The stools were pale. The persistence of the jaundice, notwithstanding energetic medication, made probable the existence of some form of profound mechanical obstruction, the precise charac-

ter of which remained undecided. The patient died of asthenia, the jaundice having continued for at least three months. At the autopsy, the gall-bladder was found to be dilated, and presenting numerous diverticula; during the manipulations it ruptured, giving exit to about ten ounces of a fluid of milky appearance and a large number of whitish gall-stones, varying in size from that of a bean to that of a pea, of which forty-one were collected. The liver was moderately enlarged; the cystic duct and the hepatic canals throughout the organ were dilated and contained the same kind of milky fluid as was present in the gall-bladder. The lumen of the common bile-duct was obliterated at the junction of the cystic and hepatic ducts. In this situation, the biliary passages were adherent to the duodenum. Beyond, the common duct was patulous to its point of entrance into the duodenum. The condition suggested the previous existence of obstruction of the common duct by a calculus, with ulceration, adhesive inflammation, perforation into the duodenum, escape of the offending calculus, and cicatricial occlusion of the common duct.

In the second case, a man, forty years old, previously in good health, following the ingestion of cold water was suddenly seized with severe abdominal pain, nausea, and vomiting. The temperature rose to 103.6°, for a few days oscillated about that figure, and subsequently slowly declined. Jaundice was from the first marked, and grew more intense. The patient became quite delirious. Treatment by means of mercurials and sodium phosphate was of no avail, and on the tenth day the patient died. At the autopsy, the liver was found to be enlargd, weighing six pounds. In the left lobe was a small, fluctuating area that, on incision, gave exit to a dirty yellowish fluid, exposing dilated canals and cavities. Section of the liver at various points permitted the escape of fluid of the same kind, in less quantity in the right lobe than in the left. The gall-bladder was contracted to the size of a large marble. It contained brownish fluid and fragments of a greenish color. The hepatic ducts were dilated. At the commencement of the common duct loosely lay a "mulberry" calculus of cholesterin about as large as a walnut. The pancreatic duct was distended with fluid.

It seems probable that in both of the cases reported death resulted from cholemia, and the deduction is likewise obvious that in both life might have been saved by operative interference. In either case, the provision of a means of escape for the bile would have constituted at least a palliative measure. In the first, radical treatment would have necessitated the performance of cholelithotomy followed by cholecystenterostomy; in the second, cholelithotomy might easily have been followed by suture in the line of the incision. The obscurity of diagnosis scarcely constituted a legitimate contra-indication for operation. Exploratory incision would have removed all doubt. The positive information thus to have been gained would have compensated for any risk incurred.

MEDICAL PROGRESS.

Hereditary Chorea.—Sinkler (*Medical Record*, 1892, No. 11, p. 281) reports three additional cases of so-called hereditary chorea. He concludes that the affection, while resembling Sydenham's chorea, differs in so many of its features that it is essentially a distinct and separate affection; that while, as a rule, there is remarkable uniformity in the symptoms presented, there may be variations. Thus, the disease may appear at or before puberty. It is not an invariable rule that if the disease fails to appear in one branch of the family the descendants of that branch have immunity. The arrest of the movements by voluntary effort is not a distinguishing feature of hereditary chorea, as in some cases voluntary effort aggravates the movements, and there are many cases of Sydenham's chorea in which voluntary effort for a time arrests the movements. Chorea among the adult insane is not hereditary chorea with insanity. The evidence at hand indicates that hereditary chorea depends upon a degeneration of imperfectly-developed cells in the motor tract or in the cerebral cortex and in the spinal cord.

Schlesinger (*Zeitschr. f. klin. Medicin*, 1892, xx, 1, 2, p. 127) reports three cases of hereditary chorea from the clinic of Nothnagel, at Vienna. He considers the affection a distinct one, usually appearing in adult life, although some cases appear early. As a rule, the transmission is from generation to generation; exceptionally, a generation is skipped. In some generations the affection may be replaced by profound hysteria. The disease is progressive. Treatment with arsenic is rarely successful.

Intermittent Influenza.—Kornblum (*Zeitschr. f. klin. Medicin*, 1892, xx, 1, 2, p. 160) reports the observation of seven cases of influenza presenting an intermittent type. The attack was preceded by a prodromal stage lasting from two to six days, and marked by languor, headache, anorexia, and malaise. After an initial chilliness, fever, for three days remittent in type, then intermittent, appeared, the symptoms being intensified during the exacerbations and moderating in the defervescent periods, though in neither instance in direct ratio to the temperature. The pyrexial periods were irregular in occurrence; sometimes two exacerbations appeared on the same day, but in the morning there was always apyrexia. The intermittent stage of the disease lasted from five to nine days, without diminution in the intensity of the febrile periods; the later of which were, in fact, preceded by chilliness, while defervescence was accompanied with sweating. In the exacerbations the pulse was accelerated to from 110 to 140 per minute, usually small and compressible, often irregular. In most of the cases nervous symptoms predominated, though catarrhal symptoms were also present. The prostration of the exacerbations was marked.

Fatty Heart with Slow Pulse.—Watts (*British Medical Journal*, No. 1624, p. 334) has reported the case of a man, seventy-seven years old, who had had syncopal attacks and an attack of left hemiplegia. For two days, while abed, the pulse was 19, soft, regular, and synchronous with the action of the heart. On two other occasions the pulse was 28. On the day before death, during an attack of syncope, two beats of the pulse were felt at an interval of five seconds. A little later the breathing ceased, and the pulse was lost for a period of ninety-five seconds. Breathing was then resumed, and

the pulse was restored, with a frequency of 35 and 90, respectively. Two hours afterward the pulse—radial, carotid, and temporal—ranged between 12 and 13, being regular, fairly full, but readily compressible. At the autopsy the heart was found to be large, pale, flabby, laden with fat; it weighed seventeen ounces. The muscular structure of the organ was atrophied and in parts replaced by fat. The cavities were dilated and empty.

Empyema of the Gall-bladder.—BÖGER (*Centralbl. f. Chirurg.*, 1892, No. 11, p. 227) reports the case of a woman, forty-eight years old, who presented a large tumor, principally occupying the left half of the abdomen. There was neither jaundice nor colic, but only a sense of distention. A diagnosis was not ventured. The patient at first declined operative interference, but subsequently solicited it, the growth meanwhile having increased in size. When the abdomen was opened the tumor was seen to be the enormously dilated gall-bladder. An incision evacuated a quart of purulent fluid. Two gall-stones, as large as walnuts, were found in the cavity of the bladder, and a third in the cystic duct. The last was removed with some difficulty. The gall-bladder was stitched to the abdominal wall and the wound was permitted to granulate. The ultimate result was entirely successful.

The Influence of the Gastric Juice upon the Virus of Hydrophobia.—WYRSYKOWSKI (*Archiv für veterin. Wissensch. —Wratsch*, 1891, No. 38) has demonstrated that the gastric juice is capable of neutralizing the toxicity of the virus of hydrophobia. For this purpose he prepared three test-tubes: one containing egg-albumin and gastric juice, and each of the two others an emulsion of the medulla of a rabbit dead of hydrophobia, the one with, the other without, the addition of gastric juice. A number of animals was inoculated beneath the dura mater with material from each of the tubes. Those treated with the digested albumin remained unharmed; of seventeen animals treated with the undigested medullary substance, all died; while of twenty-one treated with the digested medullary substance, all survived.—*Centralbl. für Bakteriol. u. Parasitenk.*, 1892, No. 11, p. 349.

Pigmentation of the Skin from the Use of Arsenic.—FÖRSTER (*Berliner klin. Wochenschr.*, 1892, No. 11, p. 262) reports a case of chorea in which a brownish pigmentation of the skin appeared after the prolonged therapeutic use of arsenic. The withdrawal of the remedy was followed by disappearance of the discoloration.

THERAPEUTIC NOTES.

The Employment of Pilocarpine for the Relief of Deafness.—FIELD (*British Medical Journal*, No. 1631, p. 701), who was perhaps the first to recommend the employment of pilocarpine in the treatment of labyrinthine deafness, insists that the cases must be carefully selected. He maintains that labyrinthine deafness is not common. The larger number of patients that hear better in the midst of noise derive little or no benefit from the sole use of pilocarpine. Hearing is best tested by means of a large tuning-fork with a wooden handle. The treatment may be employed in cases in which bone-conduction is defective. Syphilitic patients are usually much relieved; in a given case, the possibility of hereditary syphilis is to be borne in mind. Cases in which the deafness is worse after catarrhal inflammations are mostly not suitable. Patients that hear when spoken to distinctly, or in whom the deafness began with a difficulty of discriminating sounds, or who cannot make out general conversation, who hear worse when tired, nervous, or out of health, are more promising cases. In arriving at a diagnosis, the state of hearing, as tested by the watch and the condition of the drum-head, should be noted. Some cases of marked aural vertigo are benefited by treatment with pilocarpine. If disease of the middle ear is associated with disease of the internal ear, vapors should from time to time be injected through the Eustachian catheter. The usual mode of administering pilocarpine is the injection into the arm of gr. $\frac{1}{12}$ of the nitrate, gradually increasing the dose to gr. $\frac{1}{4}$. The injection is followed by the administration of half a dram of ammonium carbonate in water. The patient is well covered and copious diaphoresis and salivation take place. In case of faintness or other discomfort, brandy is given.

The Treatment of Epilepsy.—HUCHARD (*Rev. Gén. de Clin. et de Thér.*, 1892, No. 9) insists that in case the bromides fail in the treatment of epilepsy it must be determined that the lack of success does not depend upon the mode of administration. For epileptics, the bromides must be looked upon as food; about thirty grains should be given three or four times daily. If the attacks occur at night, the largest dose should be given a short time in advance. If the disease has appeared late in life, especially if there is a history of syphilis, iodides should be conjoined with the bromides. Should cutaneous eruptions appear, an intestinal antiseptic, such as naphthol or betol, may be administered. If, despite all precautions, the bromides are not well borne, borax may be tried. The agent must be free from all impurity. It is insoluble in alcohol, slightly soluble in water, and more soluble in glycerin. It sometimes gives rise to derangement of digestion, cutaneous eruptions, emaciation and conjunctivitis. If diarrhea occur, bismuth salicylate may be given. Borax is said to be the more useful in symptomatic epilepsy, the bromides in neurotic epilepsy. Treatment with borax is begun with daily doses of from seven and a half to fifteen grains, which are gradually increased to sixty, seventy-five, one hundred and twenty, and even one hundred and fifty grains. If large doses are not successful, the remedy should be withdrawn. If the attacks are controlled, the dose may be reduced to sixty grains. The remedy is given morning and night. Should the bromides and borax fail, amylene hydrate may be employed in doses of from ten to thirty grains three times daily.—*Centralbl. f. die gesammte Therapie*, 1892, x, 4, p. 209.

PROFESSIONAL IDEALS—A POLITICAL PARALLEL.

IT has been suggested that, at this season, when several thousand young men are passing from student to practical medical life, a word to them would be appropriate as to the proper aim of effort and the best method of attaining legitimate professional success. It might pessimistically be replied that *facere* will depend upon *esse*, that whether physician or not the man will do that which his essential nature commands him to do, that his life will be the realization of his inherited character. But the believers in fatalism are commonly those that want a lame philosophic excuse for indulgence of desire, when there co-exists a half-smothered subconsciousness that the desire is selfish and could be overcome if the will were strong. In opposition to this it may be truthfully urged that at the beginning of life a large measure of free-will obtains, and that in youth when unselfishness, moral fire, and enthusiasms are more potent, a conscious choice and purposive endeavor often set the beat of a life-song, and the step of a life-march.

The substance of that which one may advise is easily summarized in a very brief word, but its realization may be rendered more clear by a political parallel.

There are few sadder memorials of the tendency toward human degeneracy than the history of some of our common words. Take one of many: At one time the word "idiot" had absolutely no reproach in it; it was simply the name of a private citizen as contradistinguished from a public officer or personage. It soon came to pass that one having any large capacity interested himself in public affairs; from this the honorable man was he that labored for the public good, and the idiot was he that did not care for the common weal, and hence was stigmatized as selfish, narrow, etc. From this point the word idiot was more and more limited until finally it has come to be applied to one utterly devoid of reason and self-government, and we can now make the term but little more offensive by the adjective drivelling.

In American public life we are witnessing the same metamorphosis of the once honorable words politics and politician, but in the strange fatality of historic change the process with us is the reverse or obverse of that passed through by the word idiot. The private citizen at present remains unnamed and unconsidered, whilst the public man, the politician, is doing all he can to make his generic title the synonym of whatever is cunning and selfish and unprincipled. How many centuries will it take to make the word politician applicable only to the "safe-cracker," then to the vilest pickpocket, successively to the demented beggar, or the anarchist paranoiac? Certainly very few centuries will be needed at the present rapid rate of change. To call a decent man a politician is already about as great an insult as is possible.

The ugly thought at once presents itself, however, that the method of politics is too often and too widely the American ideal. It is true we have all grown so cunning as to shirk the word whenever we can. If our political or commercial hero happen to unite in himself, in exceptional measure, the three mundane virtues of cunning, selfishness, and unprinciple, we euphoniously call him a great statesman or an astute financier. The little statesman is the ward-boss, and the little financier is the bucket-shopper and commercial gambler of a thousand malodorous types. From "heeler" to governor, from gutter gamin to railroad-wrecker and stock-waterer, the aim is to "get a pull," to get on, literally by hook or by crook.

What is so common a psychologic feature of the modern could hardly fail to have transplanted

itself into the inviting field of medicine. It is the great national sin and danger, and also the great medical sin and danger. The trust of the patient in his physician, his helplessness in the hands of the physician, the physiologic ignorance of the people engrafted upon their gloomy medieval inheritance of magic-mongering and quackery, make them easy prey for the politician-doctor. And this Mephistophelean gentleman is thoroughly at home amongst us—coolly asking, with his elder brother TWEED, "*What are you going to do about it?*" These impudents are the quacks *within* the profession, because quackery is an affair solely pertaining to the use of medical opportunity, not to the acquirement of medical knowledge and skill. Sometimes, though rarely, the most execrable quacks are skilful physicians. It is not that they are not medically capable, but that their medical capacity is used as a tool, not as an end; as a means for selfish advancement, not for a humane purpose. If not curing will bring more money than curing, they will postpone cure until the patient has been sufficiently bled—financially—and fictitious cure is often made to take the place of real cure. These are the sneak advertisers, who are always seeking notoriety by the thousand devices of the political trickster. Every thought of their lives is how to gain new patients, and as one of the means to this end is to cure disease, they will even take the patience to try to learn this art. A consoling fact, however, is this, that therapeutics pursued in this way generally misses its object. It is to the genuine, not the simulated, love of medicine; it is to the conscience burdened with responsibility, not to the conscienceless; it is to the lover of his patient, not to the lover of self, that comes the subtle intuition and discrimination, the blessed healing power that brings health out of disease. The wise patient will not always choose the famous and popular physician. Notoriety is usually better for the practitioner than for the patient.

To the young physician standing at the parting of the ways, the ideal of quick popularity and brilliant success so often, too often, attained by the politician-doctor, offers a powerful temptation. The other method is undoubtedly slower, but it has the certain advantage of being surer. It may be safely asserted that in general government and legislation, the dominion of the corrupt boss and the typical politician is distinctly on the downgrade and brakeless. Despite his ignominious and astounding success he is doomed. Not only will his name be anathema to future generations, but his present power is being swept away from him by the great wave of righteous indignation now swelling in the American breast. Just as physical civilization and social well-being make him and his methods incompatible and expensive, so the politician in medicine has had his day of proud blooming and early rotten fruitage. In medicine he is more out of place than anywhere else. The laws of physiology and pathology cannot be duped or long trifled with. Let us not be deceived by the examples in all our eyes of the success attending cunning, scheming, barter, self-seeking, and principlelessness. These men live in constant fear, duplicity, and suspicion. They are always seeking to make tools even of their friends. They know they are in the wrong, but they must plunge on in the chosen road.

The examples of success thus gained, however striking, are rare; the great bulk of the profession being made up of the other type—the men that love their work, who, before self-seeking, wish earnestly to forefend and to cure disease. It is not only the higher wisdom, but it is also simple worldly wisdom to class oneself with the larger and better professional brotherhood. The choice on entering, the resolve purely and sincerely made, now and here, matriculates the young alumnus into a post-graduate school whose diploma assures the love and honor of his fellowmen, and the best as well as the most enduring success. Don't sneer at sentiment; it is by it that we live, and it makes all good things; don't let the scoffs of the moral suicide turn you from the fact that morals and medicine must go together. The universe is made that way, and the sneerer finally comes around to the confession. In his heart every expert trickster wishes he had made the choice that is given to you, O young alumnus, to make!

ABDOMINAL AND UTERINE TOLERANCE IN PREGNANT WOMEN.

THE medical profession is indebted to HARRIS, of Philadelphia, for a most suggestive contribution to the literature of abdominal and uterine tolerance in pregnant women. This well-known writer has for some time been instrumental in providing obstetricians with information regarding the Cæsarean operation, and his present contribution is especially valuable. By painstaking and accurate research, he

has collected twenty cases in which pregnant women have sustained penetrating wounds of the abdomen and uterus; the results in each case having been carefully ascertained, and being substantiated by reliable witnesses. To summarize the conclusions reached from an analysis of these cases, it may be stated that healthy women, leading lives that take them much in the open air, and engaged in work that develops the muscular system, frequently recover from such serious accidents as those described by Dr. Harris. The agencies that inflicted the injuries were: the horns of cattle, sharpened wooden utensils, revolver-bullets of small caliber, knives, and other penetrating instruments. In several instances, the injury was immediately followed by the birth of the fetus, and in many of these the children survived. When the accident occurs after the fifth or sixth month of pregnancy, the uterus is often freely opened, and the birth of the fetus may readily happen. In seeking an explanation for the remarkable tolerance manifested by these patients, we have another illustration of the familiar fact that recovery from operative interference depends very largely upon the condition of the patient's tissues and the power of resistance. Thus, a healthy farmer's wife may be gored by the horns of a bull, her child may be born upon the ground, and both may survive, while the rhachitic dwarf, who has labored for some hours in parturition, and upon whom Cæsarean section is skilfully performed, dies shortly after, of exhaustion.

The practical lesson that Dr. Harris so clearly emphasizes is this: that the scientific obstetrician should be so thoroughly aware of the abnormal conditions existing in his patient that when the Cæsarean operation is indicated, he will not wait until useless labor-pains have induced exhaustion, but will operate at the very beginning of, or just before, the labor. It is well, should the uterus be relaxed, to administer ergotine, by hypodermatic injection, a half-hour before the operation. Rapidity, simplicity, and cleanliness in operating will further contribute greatly to success. It is interesting, in this connection, to note that under such conditions children have, in several cases, been born by successive Cæsarean operations.

A SCHOOL OF PATHOLOGY FOR PHILADELPHIA.

The one element in which medical education in the United States has heretofore been most of all deficient is practical pathology. Efforts, all praiseworthy and some successful, are making in various cities and institutions for the improvement of the methods of instruction and the enlargement of the facilities offered to students for the attainment of a solid foundation in this important branch of medical knowledge.

Philadelphia, however, though not a laggard in the movement, does not as yet offer to students and to physicians, all the facilities for pathologic study and research that are demanded if in these days of rapid progress she is to retain her proud position as the center of medical education in the United States; and yet she has at her command resources that, properly utilized, would place her in the front rank of pathologic instruction. The Philadelphia Hospital should be made the nucleus of a great school of pathology, independent of any of the established colleges. A systematic course of lectures and demonstrations by the official pathologists could be given at hours so arranged as to be convenient to the greatest number of students. The material is ample. The facilities exist. It seems criminal that both should not be utilized to the utmost. The movement could only be productive of good, and it would come to be wondered that it had not long before been organized. In this way, one reason of going abroad in order to obtain a solid pathologic foundation upon which to build a substantial clinical superstructure would be removed.

In operative surgery, in clinical medicine, in therapeutics, in gynecology, in obstetrics, in ophthalmology, in laryngology, in neurology, in dermatology—in a word, in the entire field of practice, Philadelphia possesses in each department at least one man whose superior is not to be found anywhere, and numerous others who have the ability, the ambition, and the facilities for earnest and honest clinical teaching.

Let our colleges join with the civic authorities in establishing, as they can, a great school of pathology at Blockley, and the result will be once more to place Philadelphia foremost in medicine upon the Western continent.

SELECTIONS.

NATIONAL CONFERENCE OF CHARITIES AND CORRECTION.

Until the present century, the policy of Europe, in dealing with crime and pauperism, was the best possible, if the object had been to propagate and increase them both. The States of the New World necessarily

copied many of the methods of the old. Unfortunately, along with much that was true and wise, they copied and perpetuated many old blunders. But with the advance of modern thought, especially with the enormous widening of the sphere of scientific knowledge, have come new and better ways of dealing with the defective, the criminal, and the pauper. To spread abroad and make popular the better ways in charity and reform is the object of the National Conference of Charities and Correction, which meets annually in one or other of our great cities, and will hold its Nineteenth Annual Session in Denver, Col., next June. It combines the best philanthropy of all creeds and all shades of political opinion upon the broad platform of humanity. Its program for the year has just been issued, and is an interesting paper, its topics covering many of the social problems of the time. The membership of this conference is unique. It has no salaried officers and no selfish benefit to offer to anyone, so its doors are open to all the world; whosoever will may come in, on a footing of the most perfect equality. The fact that you are interested in its work, makes you a member, and entitles you to a seat and a voice in its discussions. Anyone desiring further particulars as to reduced railroad fare, hotel accommodations, etc., may address Alexander Johnson, secretary, Indianopolis, Ind., who will send circulars and answer inquiries.—*Science.*

THE PERPLEXITIES OF HONEST MEN IN THE PROFESSIONS OF PHARMACY AND MEDICINE IN REGARD TO "BLIND PREPARATIONS."

WE cannot refrain from alluding to an old topic again, because of its increasing interest.

The attitude of the medical profession to the chemist and pharmacist of to-day is an anomalous one, which has been increasing in perplexity year by year, until the day when there will have to be a protocol between the two professions with a view to the settlement of the difficulties is not far distant.

Every new article, pharmaceutical or chemical, is now patented and copyrighted, or protected by some bewildering or misleading name, by a class of chemists and pharmacists who a few years ago would have disdained such a course as much as Jenner would to have made vaccination a secret process.

Here are only a few examples of the kind: Two chemists, one the chief, the other his assistant, discover in the laboratory a sweet principle entirely different from the sugars or glycerin, and name it saccharin. It was raised from the position of a chemical curiosity to that of a medicinal agent, principally as a substitute for sugar for diabetics. The assistant goes to Germany, secures a patent on saccharin, ignoring the interest of his chief, and pursues the manufacture of it as a commercial enterpris. Everyone using saccharin, then, is using a proprietary article, and paying a royalty.

Take the case, also, of chloroform, to which we called the attention of our readers before. We believe that the great bulk of chloroform consumed in this country at present is wholly, or in part, produced by a patented method, and no one could compete, either in purity or in price, who holds on to the old processes.

That independent fortunes have been made by advertising diligently and expertly, keeps a vast army of eager seekers after gold alert to the chances that may lead them into the happy road to good luck. The boldness of some of these men is very great. They set about at once to dupe the medical profession, knowing that in proportion to the credulity of the doctors will depend the sales of the vaunted new discovery. Many of them are able to come with arguments and demonstrations that are all but incontrovertible, for some of these eager hunters for gold are men of learning or experience, broken down by former unfortunate ventures, or unwilling to wait the slow process, which, when patiently pursued, leads only to a moderate competency. They know another very important thing, that there is a code of ethics acknowledged by educated physicians, and some kind of artful reasoning must be used to silence the consciences of those who are faithful to their obligations—this class being by far the majority—and to this they apply their talents, too often with success. Many are the trials of faith the medical editor has to suffer at the hands of some of these sharpers, when he is called to discriminate between the manufacturer who is honestly working to supply the needs of the physician, or dishonestly trying to palm off a worthless article.

One would think that the conferences of the Committee of Revision of the Pharmacopeia of the United States would be a good point from which to originate a plan that would settle all the difficulties, but so far the Committee has been able to see no other way than to accept "the code," and abide by it. In the meantime, good and loyal physicians are trying remedies about which they can only learn that it belongs to a certain "chemical series," an intimation practically as mystical as naming it an active principle of some plant of which he never before heard. The profession has already had a practical illustration of this in that therapeutical farce, the rise and fall of "gleditschine," and it will be at the expensive burial of many other abortions, until the true men of both professions clarify the atmosphere.

It is largely a deficiency of education in certain elements of materia medica, pharmacy, and chemistry, that makes the profession such an easy prey to pharmaceutical charlatans, and it is almost entirely due to the strictly honest work of a few manufacturing chemists and pharmacists that the medical profession has such a list of choice medicaments to enrich our armamentarium.

Our present standards need revision; doctors cannot be their own druggists without neglecting duties that appertain more essentially to their profession, but this would be a far better solution of the difficulty than to submit to being taught therapeutics and materia medica by every dealer who has the money to advertise and keep a smart drummer on the road.—*The North Carolina Medical Journal.*

COFFEE-LEAF TEA.

MR. WILLIAM SOWERBY, the veteran and distinguished Secretary of the Royal Botanical Gardens, writes to the *British Medical Journal* the following note on his suggestion for adding to the number of alkaloid

beverages by the introduction of coffee-tea: When walking in the Gardens of the Royal Botanical Society, Regent's Park, and noting the extent of the collection of living medicinal and economic plants of all climes and countries there brought together in one spot, it must have occurred to all of us how very small a number of plants, out of the vast store which Nature has provided, man has bound to his service, and the yet fewer he has taken the trouble to cultivate. During the march of the last half-century in science, medicine, mechanics, steam, and electricity, how little has been gained from Nature's stores. The artificial culture of cinchona is, perhaps, the most noted of the few. Again, any step in eating, drinking, dress, is so governed by habit or fashion that he must be a bold man who tries to turn the current. This is illustrated in tea-drinking. Perhaps there is no one habit so universal; each people has its peculiar tea or closely allied beverage, and most of these have continued the same for many ages. In one it is cocoa, in others, coffee, and in many, tea; in a few special quarters of the globe nothing but *maté* is thought fit to drink, but in only one small district is coffee-leaf tea used. Now we all know that these beverages are found by man to be pleasant and agreeable to him by reason of their containing a peculiar principle called *theïne;* but yet we do not always select for our use the part of the plant containing the largest percentage of *theïne*, or cultivate the special plant with a view to afford us the most valuable part. For example, in coffee the leaves are said to contain 1.26 of theine, and the berries only 1 per cent., and yet over 110,000,000 of men use the berries, and only 2,000,000 the leaves of coffee, although 500,000,000 use the leaves of tea.—*Science.*

DISTRICT OF COLUMBIA MEDICAL-PRACTICE BILL.

The District of Columbia medical-practice bill bids fair to become a law. The homeopathists and the regular profession are enthusiastically united in its favor. The "vivopaths" and "botanic healers" are opposing it. The arguments of these latter, however, have impressed the Congressional sub-committee with the serious necessity for something to regulate them beside a writ *de lunatico inquirendo* and a prosecution for obtaining money under false pretenses. The champion of the "botanics" claimed, to the amazement even of the Congressional committee, hardened by frequent contact with cranks, that a healthy child, if treated according to the botanic method, need never be sick; that it could be educated to work and go on forever, free from all the various ills, if only his system were accurately and diligently followed. The "vivopath" claimed that thousands of people now die because physicians do not know what to do for them. He claimed to be able, in connection with his White Cross University of Science, to cure these people who are consigned to their gloomy fate by reason of the ignorance of his colleagues. As a clincher for his argument, the doctor exhibited a bottle of life-perpetuating elixir and a box of powder of some sort that promised wonders. These visible adjuncts of a claim to invisible power created a very strong belief in the Congressional committee that the bill was a necessity. —*The Medical Standard.*

CORRESPONDENCE.

THE DIFFERENTIAL DIAGNOSIS BETWEEN RÖTHELN, SCARLATINA, AND MEASLES.

To the Editor of The Medical News,

Sir: As indicated by several recent communications in your journal, the diagnosis between Rötheln, scarlatina, and measles is by no means always easy, owing to the great diversity not only in the appearance of the eruption but also in the range of temperature of the, to us, newer disease—Rötheln or German measles, which in recent years has become quite common.

In a limited epidemic that came under my notice last summer, the multiform character of its symptoms was well exemplified. The first group of cases occurred in a family consisting of a mother and four children, none of whom escaped the disease. I had attended several of the children some years before, while sick with rubeola, or common measles. In these five cases, the eruption bore a striking resemblance to ordinary measles, both in color and in the arrangement of the blotches in crescentic form. The points of differentiation appeared to be: Less efflorescence of the skin between the blotches; the rash, though very copious on both trunk and extremities, being more discrete than in measles, with an equally copious eruption. Added to this, as diagnostic points, were: The slight degree of constitutional disturbance; the almost entire absence of catarrhal symptoms; the moderate temperature—not over 101° in any case—and especially my personal knowledge of previous attacks of ordinary measles.

Widely different were the characteristics presented by the second group of cases, especially as regards the appearance of the eruption. In Case I of this group, not related to the previous group by contagion, I found a boy of nine years, of excessively nervous temperament, ill with a mild form of fever; temperature 102°, pulse 120. The chest and back were covered with a uniform scarlet efflorescence, interspersed with minute points of a deeper red hue, spreading subsequently over the abdomen and lower extremities, leaving the face nearly exempt; the whole presenting an appearance practically indistinguishable from scarlatina, of which the diagnosis was made, as probable. The tongue was moist and coated, with papillæ enlarged, but did not present the intense redness usually found in scarlatina of moderate severity; nausea and vomiting were present in a marked degree; also moderate inflammation of the throat. By the third day the rash had begun to fade from the neck and chest, but remained longer upon the back, abdomen, and lower extremities; the subsidence of the eruption was followed by desquamation of a furfuraceous character, except on the hands, where the skin peeled off in small flakes and strips; itching during desquamation was intense, but was not complained of during the height of the eruption; no albumin was found in the urine; nor did any of the sequelæ common to scarlatina develop. This case was at the time believed to be one of a mild form of scarlatina, until the irregular course of subsequent cases led to a modification of the diagnosis.

In Case II, a lad of fifteen presented, on the first day, an evening temperature of 104°, pulse 120; the rash, which was simultaneous with the invasion of the other

symptoms, had the same general character as in the preceding case, except that on the abdomen and lower extremities it occurred in patches of considerable area, leaving the adjacent surfaces free; but little of the rash appeared upon the face. The next morning, about sixteen hours subsequently to my first visit, the temperature had fallen from 104° to 102°; the pulse was 110. The temperature continued to fall, though it fluctuated between 99° and 101° throughout the progress of the case; the fauces were intensely congested, while the tonsils were swollen and partly covered with a fibrinous deposit. The tongue was moist; heavily coated at first, but at no time did it present the peculiar redness of the tongue of scarlatina. The temperature in this case was higher than I have seen anywhere recorded in Rötheln, but the pyrexia lasted only about twelve hours, and was not again approached during the progress of the case. Desquamation occurred, as in the preceding case, with itching, which was much complained of after the disappearance of the rash.

In Cases III, IV, and V, the eruption was of the character described in the preceding cases, but partial in its distribution, as in Case II; the temperature did not exceed 102°, and the cases were all characterized by the short duration and mildness of the symptoms.

It will thus be seen that the diagnosis between certain cases of Rötheln and scarlatina simplex may be exceedingly difficult, if not impossible; but upon studying the whole group of cases we find certain features common to all, that materially assist us, viz.:

1. Shortness of the acute febrile stage, even when the initial symptoms were of considerable severity, as in Case II.
2. Irregular distribution of the rash in all except Case I.
3. Absence of scarlatinal redness of the tongue.
4. Absence of the frequent pulse.
5. Absence of nervous symptoms.
6. Absence of albuminous urine.

While it must be freely conceded that the diagnosis in these cases has not been demonstrated absolutely, the weight of evidence appears to be in favor of that of Rötheln rather than of scarlatina.

While these cases were in progress, and shortly after, I heard from different sources, both lay and professional, of cases of sickness variously diagnosticated as scarlet fever, Rötheln, and roseola; of course, the latter disease is entirely excluded by the contagious character of the epidemic; while, as health-officer, I am in a position to know that no fatal cases of scalatina were reported during the prevalence of the epidemic described.

The practical importance of an absolute diagnosis in such cases is much diminished by the acknowledged contagious nature of both diseases in question; so that isolation and other precautionary measures should in all cases be strictly enforced.

CHARLES H. CHUBB, M.D.
PALENVILLE, NEW YORK.

RELIANCE UPON THE OPHTHALMOMETER.

To the Editor of THE MEDICAL NEWS,

SIR: In an article appearing in your journal of April 2d, taken from the *Therapeutic Gazette* of March 5th, some statements are made that seem to me to hardly express the true position of our science to-day, in the relative value of the different methods employed in the estimation of refractive errors.

However assured we may feel of the superiority of our methods over those of our neighbors, we ought to feel our way carefully. I am so often reminded of the question once put to me, when giving testimony of an expert character, by the counsel for the opposite side: "Doctor, is medicine an exact science?"

Medicine will be exact just in accordance with the exactness of its investigators and the measures they employ. And it seems to me that we ought not to be too hasty in either our support or condemnation.

In estimating refractive errors the value of the measure employed will depend upon the seat of error.

True astigmatism, by which I mean actual and permanent alteration in the curvature of the refractive body, is pretty generally conceded, I think, to have its situation in the cornea. True, it may occur in the effort of Nature to overcome the real trouble, and so give us lenticular astigmatism.

Lenticular astigmatism must always occur when Nature succeeds in overcoming corneal astigmatism. But this secondary error is seldom, if ever, permanent. If it were, astigmatism would be a cause of asthenopia far less often than it is. Mydriatics are only necessary in this class of cases to relieve the secondary muscular effort. And as this effort is maintained only by the utmost strain, the muscle will readily relax when relieved by the proper glass.

Time was when mydriatics were necessary to tell us the proper glass and its axis, but since the introduction of the ophthalmometer of Javal and Schiotz, we have a means of estimating these more accurately and rapidly than we have ever had before.

True, there may be cases in which we may be compelled to resort to mydriatics, as in cases of persistent spasm of accommodation, and in some cases of mixed astigmatism. But, as we all know, even mydriatics may fail us here. We do not speak from a theoretic standpoint, for in our clinics at the New York Post-Graduate School and in the Manhattan Eye and Ear Hospital we have proof of what we say in cases almost without number. Nor do we speak from a desire to fight merely for the sake of fighting, but because of a genuine love for our science, and a desire to elevate and advance it.

The value of retinoscopy, I have always maintained, was depreciated by the fact that lenticular astigmatism endeavors to overcome the error.

The ophthalmometer simply tells us that we have corneal astigmatism, its amount and axis, and experience has taught us that we can rely on its finding. We have to resort to the ophthalmoscope to ascertain the kind. Mydriatics may perhaps be very acceptable to us when we are in doubt. Even Dr. Roosa, who is enthusiastic on the subject, will, I think, admit this.

My views were put forth in the March number of the *Post-Graduate*, to which I beg to refer you.

I feel, Mr. Editor, that the article quoted in your able journal does not properly define our position. We do not entirely disregard mydriatics *in toto*. It is possible that we may come to that, but, after a reasonable trial we feel justified in saying that, given an ophthalmometer and an ophthalmoscope, in the vast majority of

cases mydriatics are unnecessary in estimating errors of refraction. Very truly yours,

Frank Van Fleet.

New York.

[We insert the foregoing in a spirit of fairness, but feel compelled to add that, in our opinion, it contains so many assumptions and errors as to render its conclusions entirely untrustworthy. The article in the *Post-Graduate*, and that of Dr. Roosa in a late number of the *Medical Record*, appear to us still more full of astonishing fallacies. The Medical News, however, cannot spare space to expose them or to continue the discussion. Time will prove that reliance upon the ophthalmometer alone is to the last degree unscientific, and however much in the interest of the physician, is not in the interest of the patient.—*Editor of* The Medical News.]

A KEELEY CURE.

To the Editor of The Medical News,

Sir: Some weeks ago, on the eve of an absence from home, I got a letter of inquiry from a physician of your city relative to the "Keeley Cure" for whiskey and opium. I cannot find the letter or recall the name of the physician, hence I send my reply to you, hoping that I may thus reach my correspondent.

I am deeply interested in this matter, as I was for fifteen years a hard drinker, addicted to regular indulgence daily and to periodic sprees.

I have been a sober man for a year, but it was only after returning from the *third trial* of Keeley's so-called cure, and realizing as I sobered up that there was no power on earth that could help me unless I had *will-power to resist* the accursed appetite. I know I can't take one drink at any time or anywhere, without going into a spree that will last as long as my stomach does not revolt. I know further, that of late years every spree results in serious affection of limbs and muscles, indicating a tendency to paralysis. The appetite comes on every once in a while, but supported by the inner consciousness of these impending results, I have been able thus far to resist, and at each recurrence I find that the appetite is less powerful in strength and endurance of time.

I never had delirium tremens, but in all other respects I have tested inebriety to its depths. Keeley can do no good of any lasting character. All the notices you see are attributable to the zeal of new converts to the fraud. I was the same way until I went back the third time, and kept my eyes open, discovering the frauds and lies. On my last visit, out of 45 patients, I found 33 were there a second or third time, and 2 for a fourth. Each time I came away he pronounced me "*cured for life*," and I was *drunk* before I left Chicago. When I saw that I was gone beyond all hope unless I could control myself and resist, then and then alone I was able to resist. Keeley has a good tonic that puts the system in good condition; the *ennui* and dulness of Dwight force you to walk to kill time. He makes you sleep until you can eat and walk; and exercise, tonic, and quiet do the rest that is done. So if a man has *power* enough to summon his *will* to his aid and exercise his cool *judgment*, as in business, he may be able to hold out—but *unless he can do this* there is no help for him. I have been to five asylums, so called, and in all could get what whiskey I wanted; *all are run for the money*, Keeley's especially. I enclose a slip from the New York *World*, which is common history of Keeley's graduate "cures."

Keeley does no more than any reputable physician can do if he can get the patient really desirous of relief, and get him to keep quietly away from temptation until he is sober and tonics have cleared out his system. There are a few exceptional cases, but they only prove the truth of my argument, that the captive once released and sound in body and head, resolves to keep free and fight for the mastery, and is never for one waking moment found off his guard.

It is a sad concession, but my own long experience and observation teach me that I am correct when I say there is "*no lasting cure for drunkenness* except the solid will-power and eternal vigilance of the patient."

This is the naked fact. Keeley does not cure the appetite, and is a consummate fraud in all respects.

You can use this in any way you see fit, and can write to any of the banks here, or to the Mayor, Hon. Peter Keen, and investigate my reputation.

Hoping this may open your eyes to a thorough investigation. I am yours truly,

Sam. McKinney.

Knoxville, Tenn.

THE TREATMENT OF PNEUMONIA.

To the Editor of The Medical News,

Sir: The old method of treating pneumonia was by bleeding; it was thought that the withdrawal of a certain amount of blood would reduce blood-pressure, and so remove congestion. It is now generally believed that this procedure does more harm than good, for, although in such treatment you reduce the blood-pressure, it must be remembered that one has taken just so much vitality from your patient.

Veratrum viride was next brought into use, and this was followed by the antipyretics, among which are quinine and the coal-tar remedies—all heart-depressants. Sometimes, alcohol and digitalis are used to strengthen the action of the heart, and so by *its* force to get rid of the congestion in an indirect way. These remedies certainly ought to be administered with the greatest discrimination, for an undue stimulation may act with injury to the patient.

A little over a year ago a new thought as to the treatment of pneumonia came to my mind: instead of throwing more work upon the heart, it would, if possible, be far preferable to remove the obstruction, since in mechanics this would be the most natural thing to do. If, for example, there were an obstruction in a water-pipe, instead of putting on more steam, we would try to remove the obstruction directly. As it is well known that the first stage of pneumonia is one of congestion, and as this is the obstruction, my aim is to remove this directly without a more vigorous stroke of the pump.

The following is my treatment: I first give a cathartic of calomel (10 grains) and a tablespoonful of castor-oil. I then apply a cantharides blister over the region of pain, commencing immediately with fluid extract of ergot, giving one dram every three hours, remembering that ordinarily six teaspoonfuls make one ounce, and by using

two of water and six of ergot, a teaspoonful makes a dram at a dose.

The action of ergot is to cause the constriction of the unstriped muscles, of which the coats of the arteries contain fibers. By this method the blood is forced away from the congested parts, and the heart is relieved. Quinine and antipyrin reduce the temperature without removing the cause.

I have had eight cases in which I have used this treatment, and in all congestion was removed in from two to four days, the temperature, respiration, and pulse in that time becoming normal, with rapid convalescence.

I have never used ergot except in the stage of congestion, for the reason that in all cases the disease was arrested before the lung was hepatized. If, however, I should see a case in which there was hepatization, I would still give ergot, not because it would relieve the hepatized portion of the lung, but to prevent the further extension of the disease.

The blister and cathartic no doubt aid in removing the congestion.

Very respectfully yours,

George E. Talbert, M.D.

Beaver Dam, Wis.

NEW YORK.

At the last meeting of the New York Academy of Medicine, held on Thursday evening, April 7th, Dr. L. Bolton Bangs read a paper entitled "Some Results of 'Withdrawal.'" The term "withdrawal," Dr. Bangs stated, has been used to indicate one of the methods of preventing conception. The extent of its use, and the ignorance of its effects, by both laymen and medical men, are deplorable. These effects vary according to the susceptibility of the individual and the frequency of the exciting cause, but they are sooner or later felt by all who practise this form of conjugal onanism. The results may not be observed until the cause has been in operation for months or years. During this abnormal performance of the sexual act, the man is watchful lest the ejaculation should take place within the vagina, and the wife is also watchful lest he should impregnate her. There is, therefore, none of that emotional freedom that happily married persons know. The act is prolonged and the ejaculation of semen is withheld as long as possible; the male organ is then suddenly, sometimes violently, withdrawn from the vagina, and the man suffers what the French call a *coup de piston*. Men who practise this form of intercourse are never sexually satisfied; they have a continual desire for coition and are never physically comfortable. The act is consequently repeated too often, always in the same unphysiologic way. The natural congestion of the prostate and the associated parts, which should be relieved immediately by the sexual act, becomes a chronic hyperemia, the bloodvessels become dilated, and changes in nutrition finally occur, indicative of varying grades of inflammation. As a result of the chronic hyperemia, the prostate and seminal vesicals lose their vital resistance and more easily become a field for the development of tuberculous foci.

It is difficult to get a definite statement from these patients as to their sexual habits. The habitual practice of "withdrawal" should be suspected when a man, especially a married man, comes complaining of so-called neuralgia of the testicles or of various parts of the pelvis, or of pains similar to those experienced by men with stone in the bladder, and of frequent urination, particularly if there is no history of gonorrhea.

Dr. Bangs related the history of two cases in which the act of "withdrawal" had been practised, in one case for a period of five years, and in the other for a period of eight years. In the latter case, among other symptoms, a severe posterior urethritis had been developed, which proved very difficult to cure. The treatment in these cases should not be severe. Strong solutions of silver nitrate seem to aggravate the inflammatory condition.

Dr. E. L. Keyes, in discussing the paper, stated that he has noticed the same symptoms as those described by Dr. Bangs. The harm is done not so much by the act of "withdrawal," but by the voluntary interference with the emotional functions.

REVIEWS.

A Treatise on the Ligation of the Great Arteries in Continuity, with Observations on the Nature, Progress, and Treatment of Aneurism. By Charles A. Ballance, M.D., and Walter Edmunds, M.D. Pp. xxviii, 584. London and New York: McMillan & Co., October, 1891.

It has not been our good fortune ever before to meet with so beautiful a specimen of medical book-making as the volume before us. The plates are beautifully done and the woodcuts are absolutely unsurpassed. It is both for publishers and authors a work of which they may well be proud. Moreover, the contents of the book are worthy of their setting. The authors have spent six laborious years, and the volume contains the record of a very large number of investigations, both in old and new directions, which are of the greatest value in settling several disputed points. In the first place, there is an absolute measurement of the diameter in cross-section of the principal arteries of the body when full and when collapsed. To supplement this, also, there are accurate drawings of the microscopic appearances of the wall of the various arteries, and very careful comparative measurements by other authors, as well as the present ones, as to the relative thickness of the internal, middle, and external coats of the arteries. Taken in connection with the pictures given of the effect of tight ligation of the arteries by rupture of the internal and middle coats, these are of the greatest value. The authors seem to have settled the question as to the amount of force that ought to be used in the deligation of the principal arteries of the body, and show that the conclusion that has been accepted since Jones's classical work on hemorrhage, in 1810, is certainly erroneous. For over three-quarters of a century it has been generally thought that a ligature should be tied tightly enough to rupture the internal and middle coats; but surely anyone after looking at the figures on page 408 would hardly venture to do so. The danger of secondary hemorrhage is most serious, and as the authors have shown on page 4, in 1606 ligations hemorrhage has occurred in

over 328 cases (over 20 per cent.); and that in 651 of these cases the deaths from hemorrhage, with the exception of cases of ligation of the superficial femoral, the external iliac, and the carotids, have varied from 51 to 100 per cent. They have shown both by the study of physiologic occlusion of the ductus arteriosus, etc., and by the study of pathologic occlusion by ligatures, from various authors and in their own operations, that simple but efficient apposition of the internal coat without rupture is the best method of deligation, and exposes to the least danger of hemorrhage.

Their suggestion as to the use of floss silk for the ligature material is certainly worthy of attention, and in the single case in which we have ourselves tried it we have been much pleased with its efficiency. The fluffiness of its surface favors the entanglement of the threads, and so prevents slipping, which, as they show, when the arteries are filled and with the ordinary blood-pressure, is very likely to occur. Moreover, they advocate what they call a "stay knot," and at least two ligatures placed side by side, so as to bring a larger portion of the intima into coaptation than is the case when a single ligature is applied. Whether this knot will stand the test of experience and be accepted by the profession remains to be seen. Certainly in the case alluded to it has answered every expectation. In seventy-one experiments which they have done the vessels have been permanently occluded by various methods without rupture of the coats.

After considering the nature of the arteries, they proceed to the pathologic processes involved in ligation, and show that it is the connective-tissue corpuscles of the middle coat of the arterial wall that proliferate, and that the clot is organized by means of these cells, and not through the leukocytes. Next follow studies of the conduct and fate of the clot, the coats, and the ligature, with a later study of the choice of the ligature, of the knot, and of the force to be employed. The authors have acknowledged the value especially of Warren's services in his admirable monograph on the *Healing of Arteries after Ligation*, and certainly on looking at the first three plates in this book and the figures on page 415 of Warren's book, we are struck by the similarity of the repair of these hollow vessels and the repair after fracture of the hollow bones. They justify the analogy that Warren draws between the callus of bone and what may well be called the internal and external callus in the healing of arteries.

The price of this book ($10) will necessarily restrict the number of its purchasers, but we recommend to all surgeons who feel that they cannot purchase the book, that they at least take it from our lending libraries and read it carefully. It is one of those books of which other books will be made; or, in the words of Bacon, one of those books that are to be "chewed and digested."

Sleep, Insomnia, and Hypnotics. By E. P. Hurd, M.D. (The Physician's Leisure Library.) Detroit: George S. Davis, 1891.

Insomnia is only a deuteropathic condition, but at times it assumes such paramount importance that measures directed toward its relief demand careful consideration. As the condition may be dependent upon so many and such varied factors, it is necessary that these causes be recognized, so that when possible their removal may constitute the first step in treatment. To comprehend the influences that act to induce sleeplessness it is essential first to have a working conception of the processes that lead to sleep. That therapeusis will be the most successful that aims at a restoration of the normal by the removal of disturbing influences, and by the simplest measures supplements and reinforces the natural tendency to the resumption of a condition of equilibrium. As the conditions differ in different cases, so will the selection of the appropriate mode of treatment differ. The therapeutist must, therefore, have not only clear ideas of the normal and abnormal, of the physiologic and of the pathologic, but he must also have at command a knowledge of the various remedies to be employed under the same and under varying conditions, so that, should one fail, another may succeed. Within the limits that Dr. Hurd has allowed himself, he has presented the subjects with which he has undertaken to deal in a satisfactory and intelligent manner. His work bears the stamp of conservative thought. We cannot do better than quote his closing words: "Physicians should be very chary in prescribing the medicinal hypnotics. . . . . Many of them, by constant or frequent use, become positively baneful. . . . First . . . . try fully . . . . all available hygienic resources."

Surgical Anatomy for Students. By A. Marmaduke Sheild, M.D. (Cantab.), F.R.C.S. 12mo., pp. xii, 226. New York: D. Appleton & Co., 1891.

This is a book for students to use with the living model, and contains the substance of a series of demonstrations given by the author to students in course of preparation for the final examinations. Many allusions to operations and injuries give interest to the text, but the scope of the work forbids that it should be regarded as a guide to the operations in surgery. In this respect it much resembles Holden's *Landmarks*, Treves's *Applied Anatomy*, and similar works intended for the use of students desirous of acquiring a practical knowledge of anatomy that leads directly to future confidence as an operator. As such, the book is an excellent guide, and one that, on account of its accuracy, may be safely recommended to all who desire a work of this character. Many anatomic points of direct clinical interest, and many matters of real practical importance, will repay a careful perusal of this work.

Botany: A Concise Manual for Students of Medicine and Science. By Alex. Johnstone, F.G.S. With 164 illustrations, etc. Pp. xiv, 260. New York: D. Appleton & Co., 1891.

We fear in this *résumé* of botanical science the life is squeezed out of it by too great compression. There are so many excellent and more complete handbooks on the subject that one cannot help wondering if the author's belief in the utility of such "concise notes" is not an error of judgment. The question also occurs, Why and in what way is it specially adapted "for students of medicine?" If the medical student seeks to learn something of the plants from which his most valuable and most used drugs (such *e. g.*, as quinine, opium, belladonna, daturine, etc.) are obtained he will not find them even mentioned.

NEWS ITEMS.

The American Pediatric Society will hold its Fourth Annual Meeting in Boston, Mass, May 2, 3, and 4, 1892. The sessions will be held in the Boston Medical Library Association Building, 19 Boylston Place. The preliminary program is as follows:

Monday, May 2—First Session.

The President's Annual Address, by William Osler, M.D., Baltimore, Md.

"Experiments as to the Value of Nascent Ozone in Certain Forms of Diseases of Children, with Demonstration of an Efficient Generator," by Augustus Caille, M.D., New York City.

"Manifestations of La Grippe in Children," by Chas. Warrington Earle, M.D , Chicago, Ill.

"An Epidemic of Alopecia in a School of Girls," by Chas. P. Putnam, M.D., Boston, Mass.

Tuesday, May 3—Morning Session.

Discussion arranged by the Council on "The Relation of Rheumatism and Chorea," by C. W. Townsend, M.D., Boston, Mass.; M. Allen Starr, M.D., New York City; Samuel S. Adams, M.D., Washington, D. C.

"Nomenclature of Diseases of the Mouth," by T. M. Rotch, M.D., Boston, Mass.

Report of the Committee on Nomenclature of Stomatitis.

"Pseudo-Diphtheric Processes," by W. D. Booker, M.D., Baltimore, Md.

"Treatment of Diphtheria by Sublimations of Mercury," by Dillon Brown, M.D., New York City.

Tuesday, May 3—Afternoon Session.

"Typhoid Fever in Children under Two Years," by W. P. Northrup, M.D., New York City.

"Typhoid Fever in Children," by Chas. Warrington Earle, M.D., Chicago, Ill.

"Typhoid Fever in Infancy," by W. S. Christopher, M.D., Chicago. Ill.

"Acute Emphysema in Children, with Report of Cases," by F. Forchheimer, M.D., Cincinnati, O.

"Pre-tubercular Anemia," by B. K. Rachford, M.D., Newport, Ky.

Tuesday, May 3—Evening Session.

Business Meeting at the residence of Dr. T. M. Rotch, No. 197 Commonwealth Avenue.

Report of the Council and Election of Officers.

Reception of the Members of the American Pediatric Society, to be given by Dr. T. M. Rotch at his residence, Tuesday, 9 P.M.

Wednesday, May 4—Morning Session.

"Prevention *versus* Medication in the Management of the Diseases of Children," by I. N. Love, M.D., St. Louis, Mo.

"Syphilitic Broncho-Stenosis," by A. Seibert, M.D., New York City.

"A Simple Method for Clinical Examination of Breast-Milk," by L. Emmet Holt, M.D., New York City.

"Sacro-coccygeal Tumor in a child Three Weeks Old; Operation; Recovery," by F. Huber, M.D., New York City.

(Title to be announced), by Henry Koplik, M.D., New York City.

Wednesday, May 4—Afternoon Session.

"Two Tracheal and Bronchial Casts," by F. Huber, M.D., New York City.

"A Case of Death from Laryngismus Stridulus in Incipient Rhachitis," by Samuel S. Adams, M.D., Washington, D.C.

"The Value of Milk Laboratories for the Advancement of Our Knowledge of Artificial Feeding," by T. M. Rotch, M.D., Boston, Mass.

Action relative to the death of Dr. John Amory Jeffries, of Boston, Mass.

An Anesthetic Investigation has been arranged by the General Committee of the British Medical Association, for report at its annual meeting in 1892. The investigation is to be chiefly clinical.

An Auxiliary Anesthetic Committee, of which Dr. Laurence Turnbull, of Philadelphia, is chairman, has been formed in this country to aid the British Association, and is desirous of adding to the data of the General Committee a collection of such facts as are indicated upon a blank furnished by the committee.

The Hyderabad Chloroform Commission has not settled the question as to the mode of death resulting from chloroform, but it has stimulated the profession to seek the cause from the clinical standpoint.

The German Surgical Society will hold its twenty-first Congress at Berlin from June 8th to 11th, under the presidency of Bardeleben. The meetings will be held in the new Langenbeck building, which will be completed about June 1st.

Kussmaul, who recently celebrated his seventieth birthday, has contributed 10,000 marks ($2500) to the Luise Sanatorium in Heidelberg, as an endowment in memory of a daughter that died in early youth.

Bacillus of Measles.—It is announced that Canon, at the Moabit Hospital, Berlin, has discovered the bacillus of measles.

Sir William Bowman, the distinguished histologist and physiologist and able surgeon, died at London, on March 29th, aged seventy-six years.

Correction.—On page 402 of the NEWS of April 9th, the words following the name of J. Solis-Cohen on the second line of the first column should read: "All the cases in which tracheotomy is indicated do not do as well by intubation as by tracheotomy."

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment, provided that the request for reprints be noted by the author at the top of the manuscript. When necessary to elucidate the text, illustrations will be provided without cost to the author.

ORIGINAL ARTICLES.

THE CLINICAL AND PATHOLOGIC SIGNIFICANCE OF VERTIGO.[1]

BY HENRY L. ELSNER, M.D.,
PROFESSOR OF CLINICAL MEDICINE, SYRACUSE MEDICAL COLLEGE, SYRACUSE, NEW YORK.

WITH a more scientific study of medicine and increasing precision in the diagnosis of disease, it becomes necessary to study clinical data with the utmost care, that they may lead to an exact localization of pathologic changes. In many diseased conditions it is possible for us to assume an air of independence toward the subjective symptoms, multiform and numerous though they are, for they may be ignored owing to the fact that the physical examination serves to unravel the hidden abnormality. Not so, however, with many diseases of the central nervous system and its dependencies. While we have methods of examination, of which the results serve only to assist in corroborating or establishing positive anatomic diagnoses, we have no positive physical exploration that allows the exclusion of leading symptoms. Every organ connected with the nervous system has its particular function to perform. The symptoms to which its change gives rise must be traced back again to their origin, demanding always a knowledge of its physiology and anatomy, as well as of those of its environment.

In introducing the subject of vertigo it will be my object to confine myself entirely to my own experience, gleaned from my records and pathologic study. In fact, I am forced from want of time to give only the conclusions of my experience, leaving the detailed consideration of the cases from which such deductions were made for another occasion.

It would be quite difficult to give a definition of vertigo. It is a sensation of giddiness, which we have all experienced, and has for its essential feature a feeling of uncertainty of position in space relatively to surrounding objects. It is always associated with impairment of equilibration. The point that I wish to make is that for perfect equilibration we require a complex of functions, including the coördination of many groups of muscles that are guided by sensory impressions received from many sources. The senses that are trained to subserve the power of equilibration, for it is not inborn, are, broadly speaking, the touch, sight, muscular sense, articular sense, a visceral sense, with the most important organs of special sense for equilibration, the semicircular canals (Grainger Stewart). It can no longer be doubted that the semicircular canals have much to do with the maintenance of the equilibrium of the body. This Flourens proved so long ago as 1828. We are gradually learning from physiologists the exact method as to how these organs perform their functions.

To retain normal equilibrium, it is necessary that the information derived from all sources should harmonize. Let the harmony be disturbed, and immediately vertigo results. Impressions contradicting each other (as Stewart so happily explains) result in vertigo or loss of equilibrium.

The fact that a disorder or disturbance of any of the centripetal impressions that regulate equilibrial coördination gives rise to vertigo must at once strongly emphasize the fact that this symptom is associated with innumerable disorders. It is a sensation of a motor process, and when severe there is actual movement. These views have been held by Hughlings-Jackson, though not new, for in 1854 Russell Reynolds said that the "feeling of equilibrium results from the harmony of our different sensations among themselves, and with the motor impulse which is their combined effect. When any one group of the sensorial impressions is distorted or removed, the balance is disturbed, and as these impressions are themselves the stimuli of muscular action, attempts are made for its restoration, producing vertiginous or allied movements." (Reynolds: *Vertigo*, London, 1854.)

Before proceeding to discuss the vertigo associated with the more grave diseases of the nervous system, I wish to call attention to its association with other less serious and frequently transitory disorders. Of these, disorders of the digestive tract are the most frequent. The giddiness in such cases has characteristics, and is coupled with symptoms that we must learn to recognize. In his eloquent lectures, which must endure as long as medical literature exists, Trousseau has described them fully, as *vertige stomachique*. The leading features of these cases are symptoms of indigestion coming on within one or two hours after taking food, with great distress, possibly vomiting, pain in the stomach, aggravated by pressure; flatulence; and long after

[1] Being part of a discussion before the Central New York Medical Society.

digestion, when the stomach has had an opportunity to empty itself, the vertiginous symptoms occur. In most of my cases, I found an amelioration of the symptoms as soon as the patient reclined, while frequently a dull pain remained for some time after the vertigo. While the vertigo lasts, if the patient attempts to walk, there is constant fear of falling into imaginary holes in the ground. This is aggravated in some cases, and may be associated with loss of consciousness. Objects seem changed as to their position and form, and a peculiarity of this vertigo is that no maneuver that the patient can employ steadies him on his feet. It is important as a diagnostic point to remember that the attacks bear a direct relation to digestion, and in some cases the patient learns to regulate the diet, successfully eliminating such articles of food as seem to increase the vertigo. Occasionally there are no evidences of indigestion, simply a troublesome vertigo that seems to be related to the process of digestion only by the time of its occurrence. While, as a rule, it is easy to detect stomachal vertigo, there are cases in which the clinical significance of the symptoms is misinterpreted, and the diagnosis becomes uncertain. This is particularly true of those cases in which the symptoms persist for a long time. Here it is found that there are no evidences of labyrinthine disease, and the reflexes are normal; the patients take but little exercise, are surcharged with nitrogenous food, tissue-change becomes abnormal, and a toxemia produces vertigo by its central impression. It is probable that in these cases the faulty processes of digestion and assimilation give rise to toxic agents, which act upon the central organ of equilibration, more particularly the fluid in the semicircular canals, with consequent unsteadiness and the vomiting which so often accompanies vertigo. This is more than idle theory, for in no other way can we explain the phenomena.

In conjunction with this variety of vertigo, and at this point where I am emphasizing the toxic origin of many of these stomach vertigos, I wish to mention the vertigo so often found in young, anemic girls, accompanied by headache and constipation. Stercoremia results from long neglect of function, and anemia and vertigo disappear when the source of the poison is removed.

The vertigo of gout, not infrequently found during the interval between the acute attacks, is frequently persistent, in some cases so severe as to incapacitate the patient from pursuing his vocation. In some cases, this vertigo is almost constant, and is relieved only when the patient is at perfect rest. It is frequently associated with considerable pain in the head, and in a few cases I have noticed a severe burning sensation in the helix of one or both ears, more particularly during the night. In some cases of latent gout, the vertigo is one of the earliest symptoms, and is accompanied by manifestations like those of stomachal vertigo, with considerable hyperacidity. In still other cases the positive diagnosis of a gouty vertigo was made only after treatment and diet directed against that habit. It has been my experience that during the acute inflammatory attack of gout, the vertigo disappears.

Vertigo as a symptom of diabetes is probably of toxic origin. It may be an early or a late accompaniment. If it be an early accompaniment, it is due largely to faulty tissue-change, and has none of the symptoms of acetonemia connected with it. If it be late, it may precede for a day or two the fatal acetonemia that ends the lives of so many diabetic patients. In some cases, it may be transitory, and may not materially inconvenience the patient. In a recent case, I found a mild form of vertigo accompanying the characteristic diabetic paresthesia, anesthesia, and other sensory disturbances, which yielded to regulation of the diet.

The different forms of nephritis and albuminuria are also accompanied by vertigo. Whether or not the vertigo be toxic in all cases is still an open question. In the acute forms of parenchymatous nephritis, it is probably due either to an edema of brain-tissue or to uremic irritation. In acute nephritis, a sudden vertigo must always be considered an ominous symptom. If it be associated with scanty urine, much edema and digestive disturbances, it is almost sure to be followed by convulsions, unless active treatment is used. In chronic parenchymatous nephritis, it may be due either to uremia, edema of the brain, diseased cerebral bloodvessels, with an overacting heart, or the accompanying ventricular hypertrophy of nephritis. In both acute and chronic parenchymatous nephritis, all grades of severity of this symptom manifest themselves. In the chronic interstitial variety, it may be looked for with considerable certainty, if there be reason to suspect disease of the cerebral vessels. In this variety of nephritic vertigo, I have found the pulse almost constantly slow, hard, and tense, in one case but 36 per minute. In that case the vertigo was so severe that the patient, a man, seventy-seven years of age, was unable to walk without assistance, and finally died with well-marked uremic symptoms. It is my firm belief that in some forms of vertigo, with nephritis and albuminuria, the cardiac hypertrophy is an important pathogenetic factor.

The different forms of vertigo thus far considered may, I think, be called toxic, and to this class might be added those well-known forms of transitory vertigo, dependent upon the physiologic effects of such drugs as alcohol and tobacco, with which we are all acquainted.

The different forms of lead-vertigo are associated with characteristic encephalopathies, and require no further discussion at this time. I simply call attention to these last-mentioned toxic vertigos, that they may not be overlooked in associating diagnosis and therapeutics.

Let us now pass to the consideration of a form of vertigo, found as the result of brain-fatigue, without other evidences of organic disease, or symptoms of anemia or hyperemia. This form of vertigo deserves particular attention. It is to be looked upon as a warning given by nature to the busy man, and calls for rest before mischief is done to brain and bloodvessel. With this variety of vertigo, not usually severe, there is a sense of weight or a tired feeling in the occipital region. While the patient is at his work, usually toward the end of the day, he suddenly, while writing or speaking, becomes conscious of slight giddiness, lasting as a rule but a few seconds or minutes, and leaving him with a desire to close the eyes and rest the head. This may be associated with general malaise, sometimes with neurasthenic symptoms, or it may be the only evidence of brain-fatigue. It occasionally happens that with this variety of vertigo the patient loses consciousness or becomes faint. As a rule, however, the vertigo with the symptoms described is transitory, and is relieved by giving the brain rest. This variety of vertigo was frequently found as a sequel in the recent epidemic of influenza, among business men who had returned to work before they had fully regained their strength.

That vertigo is an accompaniment of the various cardiac lesions, more particularly valvular insufficiencies, none will deny. But I have observed a form of vertigo that I have not found described elsewhere, associated with well-marked accentuation of the mitral first sound, and strong systolic contraction, without evidences of organic lesion. In this class of cases there is at times a veritable delirium cordis. The patient feels a sense of oppression in the precordial region, the heart strikes the chest-wall with undue force, and the vertigo seems almost continuous. This form of vertigo is most frequently found at puberty, and between the thirty-fifth and fortieth years. It may occur to you that this vertigo is due to some undiscovered cause, but those of you who have observed these cases will agree with me in concluding that the only successful treatment for the same is that which controls the violent systole, overcoming the accentuation and accompanying vertigo.

We now come to consider more particularly vertigo as it is associated with pathologic changes of the central nervous system. With diseases of the cord we have long since associated this symptom, and unfortunately the general practitioner too often concludes that faulty equilibration, with any symptom of cord-disease, means disease of the posterior columns of the cord. It is a positive fact that with vascular irregularities in the cord, either alone or associated with similar changes in the brain, vertigo is not an infrequent symptom.

Spinal anemia is as likely as hyperemia to have vertigo accompany it. In spinal anemia, the general condition of the patient, with improvement while in the recumbent posture, and the other symptoms of that condition, suffice to clear the diagnosis. A chronic spinal hyperemia would probably lead to tissue-change. The vertigo is rarely relieved by the recumbent posture, and the various sensory symptoms would aid in making the differential diagnosis. It might be important to spend a moment in considering the differences between the vertigo of locomotor ataxia and that of *sclerosis en plaques*, or multiple sclerosis. In the early stages of both diseases, before the well-marked and easily-detected symptoms manifest themselves, it is at times difficult, unless the practitioner makes a most searching examination, to differentiate positively and give each symptom its clinical and pathologic value. This is more particularly true of those forms of sclerosis that refuse to remain confined to one system, and in their progress stretch out into indiscriminate lesions. The vertigo of tabes dorsalis has usually the characteristic changes of the reflexes, with, in most cases, more accompanying sensory disturbances and greater ocular changes than that of *sclerosis en plaques*. There are three symptoms that accompany the vertigo of multiple sclerosis that are of great value in making the early diagnosis and giving the symptom its proper significance. They are: Nystagmus, fine rhythmic contraction of groups of muscles, which the patient recognizes but which yet remains unrecognized by the physician for weeks and possibly months, and finally the behavior of the deep reflexes. In the mixed form, in which we have accompanying vertigo, it is not unusual to find absence of patellar reflex on one side, with slight exaggeration on the opposite side. The sensory disturbances that are associated with vertigo, when taken alone, offer but little aid in localizing the lesion. In many of these cases the patient must be seen frequently, and carefully watched before a positive conclusion can be reached.

The vertigo of cerebellar disease has associated symptoms that, as a rule, make its recognition easy. The clinical and pathologic researches of Nothnagel, made a number of years ago, tended to prove that in cerebellar vertigo the vermiform process was most frequently the seat of disease, and this conclusion has been confirmed by others. My records show such a case, in which we had the cerebellar staggering, beginning in the prodromal stage of tuber-

culous meningitis. The post-mortem examination disclosed tuberculous deposits in the vermiform process, with the usual basilar meningeal changes. The accompanying symptoms of the vertigo, which may continue in the recumbent posture, are occipital headache, vomiting, with the characteristic gait of intoxication, and often optic neuritis. The swaying is from side to side, but the patient not infrequently falls backward or forward. There are no sensory disturbances, which is an important fact, and must aid in differentiating from the vertigo of tabes. Pathologically it is interesting to know that symmetrical lesions of the cerebellum do not, as a rule, cause more than slight disturbances of equilibration.

Ferrier's experiments with regard to the direction in which patients fall with involvement of the different segments of the middle lobe of the cerebellum show that with the anterior part involved there is a tendency to fall forward; with the posterior part involved, the head is drawn backward, and there is a tendency to fall in that direction.

With vertigo and staggering of diseased corpora quadrigemina we usually have the same occipital headache and staggering that are found in cerebellar vertigo. The close anatomic relations existing between the corpora quadrigemina and the cerebellum, through the anterior peduncles of the cerebellum, easily explain the fact of the headache and vertigo with staggering in lesions of both of these organs. It is safe, however, in making the differential diagnosis to associate staggering or severe vertigo with quadrigeminal disease, if the ocular symptoms antedate the staggering. This, it appears to me, is the experience of all who have studied their cases and the literature bearing on this question.

Vertigo associated with lesions involving the pons, usually unilateral, is accompanied with a tendency to stagger to one side, and that in the direction of the lesion. The vertigo may at first be slight, but so soon as the fibers of the pons, as they pass into the cerebellum, are involved, we may expect the staggering to one side. It may be safely said that the vertigo in these cases is not the result of paralysis of any of the muscles of the eye, for in most recorded cases these were not affected.

Hemorrhage into the cerebellar peduncles, when unilateral, has been found to produce vertigo, with the same staggering toward the side of the lesion. These symptoms would be associated with hemiplegia and palsies of the cranial nerves, according to the seat of the clot or other lesion, more particularly the trigeminus and facial, at times the sixth nerve.

Progressive neurologists are at the present time probably all agreed that most forms of vertigo are due to disorders that affect the labyrinth—speaking more specifically, the semicircular canals. The time allotted me is inadequate to enter into a full discussion of this variety of vertigo. The leading symptoms that lead to its detection are well known and require no repetition at this time. I do wish to emphasize the fact, however, that the bad prognosis that is often given by writers on Ménière's disease is not justified. The paroxysms of vertigo may be so severe as to throw the patient to the ground, with deafness and tinnitus, and yet in a few cases an almost perfect cure may result. In a case seen two years ago, all the symptoms of Ménière's disease were present—indeed, the case was "a book case"—there was a previous history of specific disease, but the patient, a young man thirty-two years of age, made a perfect recovery. A recent case might be here included under the division of aural vertigo, that had well-marked vertiginous attacks on hearing a loud noise or the striking of a gong. They lasted but a few seconds. The patient also had aortic disease.

The vertigo of arterio-sclerosis requires no mention. It is easily recognized. It is frequently associated with cramping of the muscles of the legs and a tendency to somnolence.

The rapidly-passing attacks of *petit mal* are frequently mistaken for some forms of vertigo. This error is easily made, but the condition following, if closely watched, will be sufficient to correct the diagnosis. The same may be said of the vertigo preceding other forms of epilepsy.

There is probably no cerebral lesion with which vertigo may not be associated.

Vertigo of extra-cerebral and other peripheral origin must not be overlooked, but it offers less interest to clinicians and pathologists than the forms mentioned. In conclusion, I feel that I am justified in holding that while there are many forms of vertigo, a careful study of our cases leads to a recognition of the cause and a proper understanding of the clinical and pathologic significance of this symptom.

THE MICROSCOPE AS AN AID TO DIAGNOSIS IN DISEASES OF THE UTERUS.

BY THOMAS J. HARRIS, M.D.,
OF NEW YORK.

IN the great strides made by medical science in the last fifty years, gynecology has not been behind; the diseases from which woman is a peculiar sufferer have been alleviated or conquered in a large measure; operations and methods never dreamed of by our fathers have been brought forward and have proved successful in relieving pain and saving life. One disease, however, the most dread of all, still baffles the country and city practitioner alike, and gives more anxiety than all other gynecologic maladies combined, namely, carcinoma of the uterus. Our medical journals continually teem

with suggestions as to its treatment; operation after operation is devised for its relief, but whatever the operation the universal verdict is that its success depends on an early recognition of the disease and employment of the knife at once.

The aim of this paper is to describe as briefly as possible the methods of the exploratory incision and of curetting, as an aid to early recognition of the disease, as employed in some of the clinics in this country and abroad, and to show that they are so simple as to be within the reach of every intelligent physician who appreciates the great importance of the diagnosis, at the earliest date possible, of malignant disease of the uterus, and sees so often the disease detected by the finger or speculum in so advanced a stage that operative interference can, at the best, be only palliative.

These accessions to our armamentarium of diagnostic methods have been particularly advocated and their value demonstrated by J. Veit and C. Rougal, of Berlin, in the Royal Hospital for Women in that city. The surgical technique of both the curetting and the excision is that practised to-day by gynecologists in general. For the curetting, which should be employed on the first suspicion, from hemorrhage or otherwise, of malignant disease, dilatation of the cervix uteri to the extent of from four to six millimeters, by means of the sound, is demanded; the curette is then introduced and applied to all the rough surfaces presented to the touch and that are naturally present, as carcinoma always attacks the endometrium first. The masses thus removed are then dried on blotting-paper, and thus separated from mere coagula, and then put in absolute alcohol for twenty-four hours, or, as suggested by Benda, of Berlin, in a 10 per cent. solution of sulphuric acid for from twelve to twenty-four hours, and then for an equal length of time in a solution of potassium bichromate, 1 part, to 3 parts of water. The specimens are then ready to cut. The subsequent steps demand a reasonable acquaintance with histologic technique and a knowledge of normal uterine structures, but not more than every man who intends devoting himself to special work in that department should have. As Veit has expressed it, in his *Gynäkologische Diagnostik:* "It is no play-work that is included with the pathologic anatomy in text-books on diseases of women. It is not the chapter that a man busy with a private practice can pass over; on the contrary, it forms the groundwork of every correct conception of the pathology of the female genitalia. Every gynecologist who wishes to be more than a routine practitioner must master the microscopic anatomy of the female genitalia better than, or at least as well as, the pathologic anatomy."

At the end of twenty-four or thirty-six hours the removed masses are ready for cutting and mounting. The cutting can be done by means of the freezing microtome, which, in my hands, has always succeeded very well. The objection exists, however, that this mode of section interferes with the subsequent staining, and with a little skill sections of sufficient thinness can be made with the ordinary section-razor. For the staining, an ordinary double stain of hematoxylin, followed by picro-carmine, can be employed.

For the proper recognition of the pathologic condition present, as just stated, a knowledge, to a moderate degree at least, of the histologic structure of the uterus is necessary. This, in a few words, is as follows: The cavity of the uterus is lined by a single layer of columnar epithelium. The mucous membrane is, according to the researches of Leopold, made up of bundles of short fibers, forming a meshwork, within which are contained the uterine glands, short and tubular in their character and lined by a single layer of columnar epithelium. The vaginal portion of the cervix is lined by squamous epithelium, like the vagina, in place of the columnar epithelium. In the cervix the fibrous tissue is thrown into folds, between which the openings of the minute glands are found. These glands are more wavy than those in the fundus, and lined by a basement membrane and a single layer of columnar epithelium cells. The character of these glands must be constantly borne in mind, for only by a correct conception of their nature can one detect a pathologic alteration of the tissue.

For a proper appreciation now of the condition present, not such a discriminating knowledge is necessary as at first sight seems demanded. The aims of the gynecologist can all be satisfied by considering and answering in the diagnosis the question, whether the specimen is an example of malignant growth, of benign growth, or indeterminable. If benign in character, the prognosis is favorable, and operative interference is demanded; if malignant, the whole organ, if possible, should be removed; if the result of the examination is unsatisfactory, or pointing, perhaps, to the latter condition, nothing remains but a repetition of the examination.

Now, in reference to establishing a diagnosis of benign growth, we are guided by the presence or absence of alteration in the character of the lining membrane and of the uterine glands; an increase in the number of one or the other elements without an entire exclusion of the other, or without alteration in the appearance of structures themselves, points to a benign overgrowth or simple chronic endometritis. On the other hand, an overwhelming exhibition of one element to the entire exclusion of the other, points to malignant growth, as does a duplication in the normal single layer lining the

glands, or the presence of cancer-nests in the muscular structure of the organ.

When the normal cells lose their contour and assume the spindle-shaped variety, the diagnosis no longer remains so easy, because the sarcomatous cells can be simulated by the decidual cells in abortion, as well as by the cells of the uterine endometrium in extra-uterine pregnancy, and by chronic, long-standing endometritis. In the case of an abortion the diagnosis is, however, generally rendered easy by the presence of chorionic villi. On the other hand, the round cells of the decidua, in an extra-uterine pregnancy and abortion resulting therefrom, so much resemble those of a long-standing endometritis that it is scarcely possible to distinguish between the two. Sarcoma is only to be diagnosticated when the microscope reveals masses of the typical large spindle cells, and between them the normal cells left unchanged. This fact is enough for our purposes to separate it from the picture of the benign endometritis in which the cells are all changed uniformly, even the glands being also affected. Experience and much diligence in the examination are, however, demanded in these cases, and even then instances will arise in which it will not be possible to state definitely, further than that there are no evidences of sarcoma existing in the specimens that have been rendered for examination.

With the affections of the cervix uteri the diagnosis is rendered much easier, for here, by means of the knife, pieces of sufficient size can be removed for examination.

The benign character of the disease can be safely assumed when the lining mucous membrane is preserved; when the cells in the *portio vaginalis* maintain their normal squamous form; when the glands are of the cervical order; when, in fact, there are no changes further than a thickening of the connective tissue or a number of cervical glands with retention-cysts, and between them in the interstitial tissue the ordinary round cells. Quite different is the picture in a typical case of malignant growth; here the well-known cancer-nests are seen pressing deeply into the connective and muscular tissues; the glands themselves are altered in character; their lumen is encroached upon or entirely occluded by layers of cells, not flat, but columnar in nature. The superficial layer of the lining cells may be preserved, and yet, the presence of round cells deep down in the fibrous and muscular coats is sufficient to establish the diagnosis beyond all doubt; while a destruction of the layer of squamous cells and a great diminution or an entire disappearance of the glands, with the presence in the interstitial tissue of round cells of larger and smaller size, is always to be viewed with suspicion, and, if possible, a repetition of the examination is to be demanded.

It is not to be presumed that in all cases the evidences revealed by the microscope will be entirely satisfactory; especially in the first few cases presented for diagnosis will mistakes occur; but as experience and knowledge of the appearance of the normal and the pathologic tissues are gained these mistakes or unsatisfctory examinations will be reduced to a minimum, especially if care is taken by the examiner in obeying the important rule—always to ascertain whence the piece has been removed, and also, always to be sure to make his section not parallel with, but perpendicularly to the surface of the specimen. In this way, we maintain, microscopic examination is a valuable aid and guide to the gynecologist in regard to his mode of treatment, and such it has proved in the hands of those who have employed it faithfully, and who are still employing it to-day. The number of cases in which the uterus has been removed for carcinoma, and afterward found to be free from malignant disease, is by this means much reduced, as are those unfortunate cases in which, for some reason or other, the presence of such disease has failed to be recognized until it was too late for successful operative interference.

ORIGINAL LECTURES.

HYGROMA—DISLOCATION OF THE HIP—FISTULA OF THE LOWER JAW—SUPPURATIVE ARTHRITIS OF THE KNEE-JOINT—ULCER OF THE ARM—MEIBOMIAN CYST—UNUNITED FRACTURE OF THE FEMUR.

A Clinical Lecture delivered February 13, 1892.

By JOHN B. HAMILTON, M.D., LL.D.,
PROFESSOR OF THE PRINCIPLES OF SURGERY AND CLINICAL SURGERY IN RUSH MEDICAL COLLEGE, CHICAGO.

HYGROMA.

You have noticed a small tumor on the side of this patient's neck that fluctuates. He says that he first noticed it about two months ago. On grasping it between my thumb and finger I find that is quite movable, and that it can, therefore, be easily removed. I am inclined to think that we have here a hygroma or watery cyst of the neck, because of the painlessness of the growth, its fluidity, and its disconnection with any glands. If it were an adenoma, or a tumor of the lymphatic glands, we would probably have the glands in its vicinity affected. In the present case there is no indication that any of the other glands are similarly affected. It may be a sebaceous cyst or wen. Wens are formed simply by the damming up of the duct, from which is thrown out the sebaceous material at the root of the hair-follicles. When thus occluded we have a true retention-cyst, a sebaceous cyst or "wen." Sebaceous cysts may occur on any part of the body on which hairs are found. We will now inject the surrounding tissues with cocaine, and after waiting

a few minutes for the full effect of the drug to be exercised, will remove the growth.

In all operations about the neck it is well to press your finger over the root of the neck so as to locate the veins, so that the incision through the skin may not go directly through the veins and give rise to more hemorrhage than would be necessary in the operation. We see here a vein mapped out at the anterior edge of the tumor, so that by incision directly in the center we will escape it. I shall make a simple incision directly over the tumor. It seems to be quite adherent to the skin, and, therefore, necessitates careful dissection. The contents of the tumor, being water or hygromatous, have been expressed during the operation; there remains but the sac of the tumor, which will now be scooped out. I examine the wound to see if all shreds of the sac have been removed. The shining muscular structures seem to be entirely free from any foreign body or neoplastic growth. The wound will now be irrigated, and closed with a single stitch.

DISLOCATION OF THE HIP.

This patient was before us two weeks ago. She is an old lady, seventy-six years of age, and, if I remember correctly, had sustained a dislocation of the hip, which I was unable at the time to reduce. This dislocation was an ancient one, having been received last October. Sir Astley Cooper's maximum limit for reduction of recent hip-dislocations was eight weeks. At the former clinic I said that if the strength of the patient endured, I would try at three successive sittings, by loosening and breaking the adhesions that formed about the bone in its new situation, to restore the bone to its place. I will again make the attempt to-day, not expecting, however, to fully reduce it. If this method—known as Agnew's method—should finally fail, as it may do owing to the length of time the bone has been dislocated, and if the patient still insists on our attempting to effect its reduction, it will be necessary to perform an antiseptic operation by dividing the tissues down to the bone in its abnormal situation. I desire to call your attention to the position of the trochanter, which, owing to the great emaciation of the patient, is distinctly visible. Notice the difference between the crest of the ilium and the trochanter on this (right) side, as compared with its fellow of the opposite side. There is exactly one inch difference in the relative nearness of the trochanters. Notice also the abduction of the knee; that necessarily must be a dislocation of the hip with the bone backward. Owing to the emaciation of the patient it is easy to locate the head of the bone, which is here in the sciatic notch.

Remember that I am not so much expecting to reduce the dislocation this time as to free it from its bands of adhesion, and this process is not unattended with danger to the patient, for we may fracture the thigh if our efforts be too violent, especially in a patient of her extreme age. I am now keeping the knee abducted, in order that the untorn portion of the capsular ligament may remain relaxed as much as possible. When this bone escaped from its normal cavity the thigh must have been abducted, so we must keep it in that general direction in making efforts at reduction. If you notice, we have gained considerable in the motion of the joint since the last clinic day. I can feel the head of the bone slipping now, and it is probable that at another time we shall be able to make more progress. This is, perhaps, all the manipulation of the hip that with safety to the patient it would be practicable to make to-day. One more attempt will be made one week from to-day. I do not think inflammatory swelling will take place in the adjacent tissues as a result of the present manipulations.

FISTULA BEHIND THE INFERIOR BORDER OF THE LOWER JAW.

We see in this case the opening of a fistula just behind the inferior border of the lower jaw. Following up this fistulous tract I find loose pieces of bone that require removal. These pieces of bone are undoubtedly exfoliations. The teeth are decayed. Of course, there is but one thing to do for this boy, and that is to remove the loose pieces, to scrape out the diseased portions of the bone until healthy tissue shall have been reached, then close the wound aseptically and expect it to heal by primary union. It is the opinion of my distinguished colleague, Professor Senn, that by the use of decalcified bone "chips" we are enabled to support the new granulations, as they might be supported by the bony framework of an aseptic sponge, and thus hasten the process of bone-repair.

CHRONIC SUPPURATIVE ARTHRITIS OF THE KNEE-JOINT; DIAGNOSIS AND AMPUTATION.

This patient came into the hospital a day or two ago with violent pain in the knee, that has lasted, she assures me, for several months. The pain was so acute that she could not straighten the leg. As you notice, the knee is considerably swollen; it was almost impossible to make a satisfactory examination when I first saw her. Now that the patient is under the influence of ether we proceed to examine the knee-joint carefully, first, by an external examination, and, secondly, if necessary, by making an exploration of the joint, and it may be that we shall find that the injury is even more serious than it seems from an external view.

The first thing that will attract your attention, I have no doubt, is the increased size of the knee-joint as compared with its fellow; and the next thing is the apparent extreme breadth of the patella. On raising the extremity we find that there is complete ankylosis, perhaps due to contracture of the muscles, possibly due to the existence of true bony ankylosis. You see the actual difference in the circumference of the two knees by measurement is five centimeters. If I press at this point (illustrating), I find a non-fluctuating but elastic swelling, as if it were a tumor pressing out under the edge of the patella. If I press it along the edge of the patella, I fell that same elastic swelling pushing out apparently beneath the patella. On the other side, at the internal border of the patella, I find general inflammatory thickening. We evidently have here either a tumor of the knee-joint or fungous or exuberant granulations of the knee-joint from long antecedent inflammation, and undoubtedly from the presence of the steady pain there must be more or less purulent fluid in the joint itself. As it is impossible to make an exact diagnosis from the external appearances of the limb, it will be necessary to make an exploratory incision. If you will look at the anterior border of the knee, or its anterior surface, you see

that the swelling is quite uniform, so that it must be more than a simple diffuse inflammation of the knee-joint. The steady pain, without tenderness, would not be so indicative of tuberculosis of the knee-joint as if great tenderness were present; but by superficial pressure I was unable, in the examination yesterday, to excite any great amount of pain, and even deep pressure in certain situations did not materially increase the pain. The pain seemed to her, as she expressed it, "deeply within the joint." The patella is immovable, showing that at some antecedent time inflammation had taken place, and by its results the posterior surface of the patella is firmly glued and now adherent to the joint. I shall make an incision along the internal border of the patella directly through the tissues, so as to open the joint on the inside, and then make a similar incision on the external border of the patella, so that we may freely inspect the joint, and then, if necessary, I can connect the two incisions below and turn the patella directly upward. I should explain to you that this patient has been fully advised that she may have what was formerly called a gelatinous infiltration of the knee-joint, something of the nature of a colloid, which is doubtless sarcomatous in its nature or from extensive erosion of the bones composing the joint, and that it may be necessary to perform an amputation. The patient and her friends are fully forewarned that the operation may proceed to any necessary extent. I feel quite confident, as I said to you, that there is pus in the joint, which you now see. Before we proceed further, we will wash out the cavity, then I shall turn up the patella and carefully examine the joint. Several times in recent abscesses of the knee-joint I have found that it was only necessary to simply put a drainage-tube directly under the patella and carefully irrigate with an antiseptic solution, leaving the tube for several days for the purpose of drainage. However, in such a chronic case as this, on account of the changes that have taken place and the contraction of the tendons, irrigation and drainage alone will not suffice. We must, therefore, perform what is called arthrectomy if we wish to remove all of the structures that are involved in the disease. Arthrectomy is performed on the lines that I have indicated, now uniting them with a curved incision. In a normal joint the incisions that are now made will enable us to turn the patella upward with a flap. In this joint, bound down as it is by long previously existing inflammation, it is not sufficient, as the patella is firmly ankylosed to the lower extremity of the femur. We see that a burrowing abscess has extended directly upward for a distance—without exploration I do not know exactly how far—probably to the extreme limit of the synovial sac. You remember that the synovial sac itself extends a little upward beyond the upper border of the patella, in some instances from an inch and a half to two inches.

Further exploration of the condition of this joint is needed. A true arthrectomy consists in turning back the joint, opening it fully and completely, so that every portion of the soft structures involved and the cartilage as well may be reached and removed. Nothing less than that constitutes an arthrectomy, it being different from a resection. In a resection we saw thin slices of the bone; in arthrectomy every bit of diseased cartilage, every bit of the softer structures and portions of the diseased bone are scraped off. In resection we take out the entire joint. The patella has now been removed from its false attachment to the lower extremity of the femur. As I lift the member, almost by its own weight, the adhesions binding the joint together are broken. Our probe must be aseptic, because it may be the pus has not penetrated into the deeper structures of the joint, and if so, we will try again to secure ankylosis after having cleaned out such of the tissues as are diseased. I very much fear, however, that the entire extremities of the femur and tibia are involved in this disease, and in order to cure the patient and to prevent exhaustion from the long-continued drain of pus, it will be necessary to remove the limb. I find the joint is practically honey-combed with sinuses leading in different directions. I now free the extremity of the bone a little. You notice that the bone is so soft that the handle of the scalpel can be pushed into it, and in such a state of disease that the saving of that joint, or an attempt to save it, would ultimately cost the patient her life. A point to determine now is the condition of the tibia. I shall make a deeper incision into the tissues. I find that the tibia is also diseased to an extent that forbids any attempt to save the limb. You see we have been careful in the examination of this joint, so that if there had been any chance to save it we would at any time have it in our power to do so. As it is now, the more it is examined the more extensive the disease is, and we must resort to an amputation.

Here we are able to make an amputation at the "point of selection." What I mean by the point of selection as contra-distinguished from any other situation, is that here we are able to make the amputation at the point we prefer. We must consider the question with reference to the wearing of an artificial limb. Some of you lately witnessed an amputation by my colleague, directly through the knee-joint; in that case the knee, from previous disease, had already become bent at a right angle, the patella was fastened down to the lower extremity of the femur, and, as he explained admirably, that stump was already perfect. It would not be so with a stump that you desired to make new, when the tissues had not become similarly ankylosed or the bone drawn down.

The published experience of operations at the knee-joint is unsatisfactory, so far as their after-results are concerned. The wearing of an artificial limb is made easier by making the incision above the swollen portion of the thigh. Remember what the condition is when an artificial limb is placed on the stump. The weight of the body does not rest upon the end of the limb, but is sustained by the sides. Hence we desire the bone itself to be rounded and conical, and not bulbous at the end. When it is bulbous you find more or less difficulty in wearing an artificial limb. When one is so fortunate as to have one of those rare cases of the patella already glued down on the end of the bone, it would be proper to make an amputation by disarticulating the bone. Under ordinary circumstances it is better for the patient that the limb be amputated above the condyles than through the joint. In this case, in order to make sure of having sound tissue, so that the wound will heal by primary union, we go above the inflamed tissues. I shall operate by making a transfixion; I pass the knife until I reach the bone in front, then by depressing the handle I raise it a little

so as to clear the femur, and pass the knife close to the bone directly in the manner you see. I carve out my upper flap, which is the short one, that is now seized by an assistant; I take the catling and carry it under the bone, pass it in the heel of the incision; I now bring it out, if possible, exactly in the same place; I keep the edge of the knife close to the bone, so that I shall have sufficient flap to cover the end of the bone when it shall have been sawn through. I turn the knife outward and carve a flap outward. The softer structures are now severed; I take the scalpel and cut through the periosteum; it is cut a little lower down than the point at which I wish to sever the bone. I now press the periosteum directly upward, and, as you see, owing to the long-continued disease, it peels very easily; I shall have plenty to cover the ends of the bony stump. This bone is not very healthy even at the point of amputation. It is quite brittle, crumbles easily under the saw, and, as will be seen, there are evidences of medullary inflammation. We now remove the retractor and pick up the bloodvessels. We have here, near the bloodvessel, the sciatic nerve, which we will strip backward, pull out and cut off high up, in order to prevent a neuroma or irritable stump. We now separate the bloodvessels. In cutting off the larger vessels it is well to tie the vein as well as the artery. This may either be included in a single ligature or tied separately. The object of tying a vein, as you know, is not, of course, to prevent hemorrhage, but to prevent any exudations from the flap or infective organisms, from gaining direct entrance into the vein, and thus leading to pyemia. I have now cut into another abscess directly in the upper flap, one entirely unsuspected. I shall now have to remove a great deal more of the tissues in order to free the stump from this infectious material. The cavity is easily seen in the specimen removed. I shall remove enough of the tissue to make sure that all of the pus-bearing portions are removed. It will be perfectly safe now that the arteries are secured, and we can remove all the infected tissues at our leisure. The muscles are dissected up by the previously existing inflammation. You can see layers of muscle between the intermuscular substance. As we have plenty of material, it would be well to even further retrench this flap, as it seems edematous. We must also remember that the lymphatics lie in the meshes of the fatty structures between the muscles, and that septic infection is conveyed into the system through them; so it is necessary that all portions of diseased structure shall be thoroughly removed. I had supposed I was going high enough in making the amputation to escape infection, but an examination of the flap does not indicate it. This muscular structure, as we look at it, seems watery and abnormal in appearance, but the changes are doubtless due quite as much to atrophy of the muscle itself and its commencing fatty degeneration, as from any actual disease. It is the intermuscular substance that is diseased and in which the pus is seen. It will be noticed, too, that when you make an incision directly through the healthy muscle, as in this case, there is vigorous contraction. The one I am raising with my forceps does not contract on pinching, showing an antecedent chronic pathologic condition. This is a somewhat tedious process we are going through at present, picking out the abscess foci, but it is useless to put together flaps that are in a state of disease and then expect primary union. We must, if possible, secure sound tissue. We may expect parenchymatous oozing from the cut ends of the muscle; spurting, however, ought not to occur, and it will be prevented. I think, as a precautionary measure, we will rub the cut surface with iodoform gauze precisely as if we were treating a tuberculous abscess. It seems to be now comparatively clean. Of course, this is not a typical flap, but you see it comes together well; on account of the conditions that guided the course of the flaps it is practically, as it now stands, a circular amputation. The time spent in securing accurate apposition of the flaps is never wasted, as it is quite worth while to make a neat-looking stump and have the cut edges of the skin entirely in apposition. There are two advantages in the use of silkworm-gut for superficial sutures; it seldom slips during the operation, and it prevents the tissues from moving from place to place. A single knot does not slip; it is aseptic, non-irritating to the tissues, and it can be left in place longer than a silk stitch. You notice I am putting these stitches in pretty closely, but I do so in order that we may secure accurate coaptation. The drainage-tube here inserted will not be left in place very long, usually removed about the third day. The object of using a drainage-tube is to secure the evacuation of any redundant exudate, and, for what a machinist would call a "tell-tale"—*i. e.*, to discover early whether hemorrhage is present, this being easier told when a drainage-tube is inserted than when it has been omitted. If you notice, I have a flap absolutely without tension. While there are two side incisions, they are ordinarily not necessary, yet we will have here a very serviceable stump; it is certainly smooth and free from puckering or straining.

There is one point in handling stumps that I think it is well to remember. Always pull the muscles away from the bone; this prevents the patient suffering much pain, and by so doing you are easily enabled to handle it during the period of repair, sometimes without causing any pain to the patient. Carelessness in handling the stump, and not making extension, always works injury to the patient and retards healing.

We will find an advantage later in putting adhesive strips on two sides of the stump, and thus have them run over a pulley and making slight extension by a light weight. That method is almost uniformly practised in certain hospitals.

ULCER OF THE ARM OF INFECTIVE ORIGIN.

It is absolutely necessary, in order to form any sort of opinion as to the condition of this ulcerated surface, to ascertain whether or not it proceeds from the bone. Please notice these fistulæ and their longitudinal character. They extend from the index to the second fingers along the radius and its outer border just outside the biceps muscle. Consider what structures lie underneath. We have here a specific ulcer of some sort that is travelling in the course of the superficial lymphatics toward the body. The poison comes from the outside and its operation is confined to the superficial fascia. It is not lupus or tuberculosis of the skin, because lupus is not likely to follow in that continuous tract. This case is more like one of malignant pustule in its characteristics than anything that can be seen by the naked eye. It is not, however, malignant pustule, because that would have fever as a

symptom. The child's skin is cool; the tongue is clean, showing that the digestive apparatus is not affected. We doubtless have here some form of infection, perhaps not easily explained, unless we make some cultures from these ulcers. I have repeatedly seen oyster-dredgers who had these peculiar-looking ulcers, originating from some infectious material on the outer surface of the oyster-shell, and almost invariably it is found to follow the lymph-channels. We have, then, a case of poisoning of the superficial lymphatics of the palm. It is to be treated, of course, by something that will destroy the germ. It would be well to take certain cultures of these ulcers for observation. I would treat the ulcers by injecting them thoroughly with iodine, taking every ulcer separately, making a thorough hypodermatic soaking of the fungous tissues underlying each. Then I should apply a compress wet with iodine directly over each of them. In order to prevent sticking or gluing fast to the fungous granulations, it might be well to use iodine ointment, which would prevent adhesions of the iodoform gauze.

MEIBOMIAN CYST.

Here is a man with a "stye" on the left eye, and what appears to be a meibomian cyst on the other. Both doubtless originated in the same way. The patient is of hemorrhagic diathesis. "Forewarned is forearmed" in such cases. Having made an incision, we will proceed to close it up with a stitch, which otherwise I would not do. I have now made an incision directly through both, and will simply turn out the sac in each case. You notice how freely this patient bleeds. In an ordinary patient we would not have such hemorrhages. I shall put a stitch through each of these minute wounds. The operation is simple, as it consists in cutting through with bistoury, then taking the forceps and prying out the little sac. I shall put a stitch through the wound, and then place a collodion covering over it. I have now closed the wound with a stitch, and shall compress it with the forceps, and while so compressed and the skin is held, we will apply to it collodion. I retain it until the collodion has begun to form a film. In that way I expect to control the hemorrhage. Failing in that, we will apply a *serre-fine* and leave it on the lid for several days; but you see we have managed to stop the hemorrhage in this case.

OPERATION FOR UNUNITED FRACTURE OF THE FEMUR.

This unfortunate patient, whom I now bring before you, had an operation performed for an ununited fracture of the femur about eight weeks ago. I had intended to again operate upon him three weeks ago, but he was seized with the prevailing epidemic of la grippe, and he had some fever, and of course the operation was considered out of the question at that time. You notice that the femur can be moved in any direction; the man cannot walk upon it, even with the use of an apparatus sometimes recommended for ununited fracture of the femur. If you remember, on cutting into this—and a long and tedious operation it was—we found the lower fragment of the femur had passed directly backward through the biceps and pierced the adductor magnus muscle. The cause of the failure of union was the interposition of muscles between the fragments of bone. It was impossible, under such conditions, to keep the bone in place, so that after a reasonable period had elapsed, as he supposed, he came to the hospital, and an attempt was made on a previous occasion before you to reunite the bones. On that occasion I made the incision down to the bone, freed the fragments from their impalement, and wired them together. During the administration of the anesthetic the patient took ether badly, struggled greatly, and the wires were broken. I then passed the drill into the bone, and left it *in situ* for several days; but, as might have been expected under such circumstances, the operation was unsuccessful. It is proposed now to make one more attempt, to cut down, expose the ends of the bones, bring them into apposition if possible, drill them, and peg them together with ivory pegs.

Statistics show that operations for ununited fracture of the femur have not been successful, but most of these statistics are drawn from the pre-antiseptic period, and are therefore no real guide for us in these days of aseptic operations.

You will notice that the old incision has pretty fairly healed. I shall make the incision in the old line. Part of the silver wiring, not corroded, is seen, and it will be remembered at the time that it was the only wire obtainable at the clinic. The tissues are perfectly sound about the bone, and so far as the former operation is concerned, it is evident that the bone has not been materially injured. There is usually little difficulty in reaching one of the fragments; it is the other fragment that will give us the trouble. Of course, we must expect to have some hemorrhage from these recently inflamed and irritated tissues; it would otherwise not be healthy bone. We had great difficulty in securing the upper extremity of the lower fragment at the previous operation. Of course, the main difficulty of the operation is in getting the lower fragment out of its buttonhole position in the muscular and fibrous adhesions to the opening of the wound. If you notice, the lower fragment is almost the length of my finger from the surface; I cannot place my finger on the bone, because it impinges upon the muscular structures above the bone. As a matter of course, we are always liable to tear an artery by the upper extremity of the lower fragment in its manipulation; we are less likely to do so in this case than in an ordinary ununited fracture of the femur, because the upper extremity of the lower fragment has been cut off and is smoother than when it was originally broken. The real difficulty of the operation is now apparent. I shall endeavor, while the limb is fixed at this angle and the bone brought near to the surface, with this retractor, to make an opening through the muscular and fibrous structures that lie on the bone, until I can reach it and separate the fibers directly over the bone. If that is not practicable, I shall be obliged to make an incision, which I dislike to do, in this situation (illustrating), because, as you see, it is impossible as the bone remains to determine exactly the location of the femoral vessels. The lower fragment seems to be even more securely locked under the upper fragment than it was at the time of the former operation. One of the difficulties under which we labor is the fact that, in a fracture just above the condyle, if I enlarge the incision much in a direction below, I shall interfere with the joint. I do not wish to do that. You notice that the bone is still tightly locked by the dense

structures at the end. I shall have to free it by the knife. We have at last succeeded in getting the end of the bone. I shall now split the periosteum just where you see, and separate it. The periosteum is firmly adherent to the bone, and you will remember that at the last operation this was peeled up for a distance of about an inch and a half, and it is quite adherent over the entire end of the bone, there being enough periosteum left to cover. It is a practical demonstration of the wisdom of that surgical procedure which has been handed down to us from the past—viz., to preserve the periosteum as much as possible. I now saw the end of the lower fragment to correspond with the upper fragment. The lower fragment is extremely soft and brittle; it can almost be torn apart. As the lower fragment is too soft for the drill, I will try the upper fragment. I I can drive a peg directly in without making an opening. Owing to the softness of the lower fragment of bone, I shall now make a figure-of-eight over the two pegs thus driven. This bone must be held absolutely in position while the stitches are being put in. There seems to be no spurting of the vessels, but there is a good deal of oozing, as would naturally be expected in a wound of this extensive character and from old cicatricial tissue. There does not seem to be a great deal of hemorrhage at present; but if we find after a while that arterial blood flows in great quantity, the only thing for us to do is to cut down on the femoral artery in Scarpa's triangle and tie it; but this bleeding, I am sure, is nothing more than venous, as it is quite black, and although free, it does not spurt. We will compress the femoral as a temporary precaution.

I propose to leave the flat retractor under the junction of these two bones for four or five days at least, until the soft parts have acquired their proper situation. Temporary compression of the femoral artery was all that was required in this extensive operation-wound, as you see the hemorrhage has now ceased.

The leg will now be dressed in the following manner: Bichloride gauze packed in on this retractor and washed off carefully with bichloride of mercury, then a little cotton, then over that a plaster-of-Paris splint extending from the ankle to the head of the femur.

PHIMOSIS COMPLICATING SIMPLE VENEREAL ULCER—CARCINOMA OF THE BLADDER AND PERINEUM—URINARY FISTULA FOLLOWING SUPRA-PUBIC CYSTOTOMY—MALIGNANT DISEASE OF THE FEMALE URETHRA.

A Clinical Lecture delivered at the Arapahoe County Hospital.

By WM. P. MUNN, M.D.,

GENITO-URINARY SURGEON TO THE ARAPAHOE COUNTY HOSPITAL; PHYSICIAN IN CHARGE OF THE CITY HOSPITAL FOR CONTAGIOUS DISEASES, DENVER.

PHIMOSIS COMPLICATING SIMPLE VENEREAL ULCER.

Here is one of the more common types of veneral disease, which, with its existing complication, demands for its management a great deal of patience on the part of both patient and surgeon, together with a considerable degree of good judgment.

This young man some two months ago contracted a simple venereal sore that was located at the junction of the foreskin and penis, the foreskin being then well retracted. The irritation of the ulcer caused some discomfort, to relieve which he drew the foreskin forward, covering the glans entirely, and in this position it has since remained, much to his disgust. The foreskin has swollen and become edematous, while the glans is so effectually hidden that it is impossible to reveal it by any amount of manipulation. The secretion from the sore is retained and causes an immense amount of irritation. Operative interference in such a case is not to be lightly decided upon. The simple venereal ulcer—more often called by the old name of chancroid or soft sore—is usually, as in this case, the source of a free discharge; sometimes thin and ichorous, sometimes thick and creamy, but always contagious; any abrasion then with which it comes in contact is converted into another sore, similar in character to the original one. And this is a distinguishing feature of the disease which is expressed tersely by saying that it is "auto-infectious." By this is meant that it can re-infect the patient; there is practically no limit to the number of simple venereal ulcers he may have.

So you can see how the management of this case of phimosis is complicated by the coëxistence of the simple venereal ulcer. Under other circumstances immediate circumcision would be the unquestioned method of treatment, but under existing circumstances a waiting policy has governed the treatment. As it has been impossible to expose and make local applications to the sore, we have simply endeavored to keep it as clean as possible and to lessen the discharge, using free irrigation with a 1:2000 solution of bichloride of mercury, and being very careful to get the tip of the irrigating-tube well back between the glans and the prepuce. Two weeks of this tentative treatment has failed to do more than lessen the irritating qualities of the discharge; the preputial edema is as bad as ever. I will now expose the glans by slitting the prepuce upon its upper surface with scissors, taking care to first thoroughly wash away all the discharge that may have accumulated. As soon as the hemorrhage has somewhat ceased we will apply a dressing of powdered tannic acid and bismuth, which will form a protective scab over the wound, and perhaps prevent it from becoming infected. The prepuce is now sufficiently relaxed to permit of more careful cleansing of the glans and removal of all discharge.

CARCINOMA OF THE BLADDER AND PERINEUM.

This patient you have seen before. He is a German, twenty-seven years of age, and has been in this country but two years. Previously to coming to America he was in perfect health. A year ago, while residing in Toledo, Ohio, he drank freely of the water of a well which had the reputation of causing stone in the bladder, and some time afterward he began to have difficulty in urination. Last summer his trouble had progressed to such an extent that a surgeon in this city performed a perineal cystotomy for calculus and scraped away a phosphatic shell lining the base of the bladder; he also scraped away some material thought to be part of a new-growth. The perineal incision never healed, but became surrounded by a mass of hardened tissue that soon oc-

cluded the urethra and began to slough in the surface of the wound.

He entered the hospital in October last with the hope of having a radical operation performed for the removal of the disease. The condition then existing was such as to contra-indicate any operative measures. The anterior portion of the urethra was absolutely occluded, the cavernous bodies were involved almost as far front as the pubes, the structures of the perineum were all included in one hard and stony mass, while an examination by the rectum showed the posterior bladder wall to be so infiltrated that it felt to the finger as hard and resistant as a child's head coming through the pelvic canal. Operative removal of the growth would have been impossible, since such a measure would have meant the removal of everything between the pubes and rectum. Even if an operation of such magnitude were anatomically practicable, it would have terminated with the patient dead upon the table or dying within a few hours from shock.

We have done little for this man. He was for a time able to control the vesical sphincter and could urinate at will through the perineal wound; that control he has now lost and his urine dribbles away constantly. The mass of the tumor of course interferes with the normal action of the bowels, and they are moved daily by means of copious enemata. He is kept comfortable by hypodermatic injections of morphine.

His strength is rapidly failing and it is only a question of a few weeks until the case will terminate fatally.

For a time I used in this case the treatment of Mosetig-Moorhof, which consists in the injection into the tumor of a dilute solution of methyl-violet, but there was no apparent benefit, and as the suffering arising from the injections was most intense their use was discontinued.

The character of this growth can only be positively determined post-mortem, but it is probably a carcinoma, although his age is an argument against this supposition; still the clinical picture of the case is more nearly that of carcinoma than of any other new-formation. Fibro-sarcoma of this region is somewhat common and is quite within the probabilities, or it is possible that the growth may be of a mixed character.

PERSISTENT URINARY FISTULA AFTER SUPRA-PUBIC CYSTOTOMY.

You will remember this man as the one on whom I operated last October for a good-sized vesical calculus, removing it by the supra-pubic incision; again in December he was submitted to operation, this time the perineal incision being made for the removal of a small uric-acid stone, that was lodged or rather encapsulated at the junction of the prostatic and membranous urethra. Nothwithstanding the long rest afforded to the bladder and to the supra-pubic wound by this second operation, there still persists a small urinary fistula. Sometimes a whole day passes without any escape of urine, but at other times a little escapes every time the man passes water. He is decidedly better, however, than a few weeks ago, and will probably soon be entirely well. The treatment consisted in cauterization of the fistulous tract with chromic acid, a few crystals of which are fused on a probe, passed into the fistula, and brought well into contact with every portion of its walls.

What cause has operated to bring about this persistent fistula? The operation was an uncomplicated lithotomy and the wound should have closed quickly; but several causes acted to prevent this, among them the fact that the patient had a very large bunch of pre-vesical fat which sloughed out; and the encysted stone in the urethra partially obstructed that outlet and thus kept up a more or less continuous backward pressure of urine, which escaped through the supra-pubic opening.

Both of these factors are worthy of more extended discussion, for they are important as illustrating a danger connected with the operation and too seldom mentioned by its advocates—one also that illustrates a source of uncertainty in surgical diagnosis.

There can be no doubt that this case has proved that the perineal incision at first would have given more satisfactory results; it was decided against at that time principally on account of the supposed size of the stone, which seemed to be about two inches in diameter. The subsequent history showed this to be an error—the stone was only an inch and a half in diameter, was oval and flat, and but half an inch in thickness. The sacculated stone in the urethral tract, being at that time unsuspected, played its part in causing this deception, for its contact on withdrawal of the sound was thought to be due to the vesical calculus.

This patient, too, had too much fat for an easy, typical supra-pubic operation; the fat rendered the bladder difficult of access at the time of operation; it sloughed afterward, opening up connective-tissue planes, permitting extravasation of urine into the scrotum, and making the convalescence most tedious. All of these facts point to the conclusion that the perineal incision would have been the easier and safer at the first; as you see, it had to be resorted to finally when the sacculated stone in the urethra was discovered. The scar of the incision then made can now hardly be seen, while this supra-pubic wound still leaks a little and has been a very disagreeable feature.

Another complication of this case, due directly to the extravasation of urine, was an abscess of the left testicle, which formed about a month after his first operation, and was opened at that time by Dr. Parkhill. The testicle is much shrunken, as you may see, but it still retains its characteristic tenderness, and is no doubt, to some extent, still functionally active.

I will now pass a large-sized sound into this man's bladder, as I have done at intervals of a week or ten days for some time past, in order to prevent or lessen any tendency to contraction and consequent stricture at the location of the scar of the incision into the urethra. Notice that the sound is not grasped firmly and forced in, but, on the contrary, the handle is simply supported while the sound practically slips in by virtue of its own weight; notice, too, that I allow the sound to swing far to one side in passing the twisted, slightly contracted site of the incision. Too much emphasis cannot be laid upon gentle handling of the urethra, and I believe that if every physician or student, before attempting to employ the sound upon others, was first compelled to pass the instrument once or twice upon himself, he would have an abiding memory of the sensitiveness of the urethral mucous membrane, and might consequently be more gentle in his manipulations of others. You will notice,

as the sound is withdrawn, that there is no blood on it; this ought to be the rule in most urethral examinations, and would be if urethral examinations were as a rule more gently conducted. Of course, some urethræ are over-sensitive and bleed more easily than others, but every urethra is not so, and a large proportion of examinations may be conducted without the occurrence of hemorrhage.

MALIGNANT DISEASE OF THE FEMALE URETHRA.

Until six months ago this woman, who is sixty-four years old and unmarried, was in perfect health. She passed the menopause at the age of fifty. There is no history of malignant disease in the family, but two brothers died of consumption.

Six months ago she began to have pain during and following micturition, with great frequency of that act, pain on sitting down, and a muco-purulent discharge from the vagina. She has been under treatment by several physicians, and says that she does not suffer so much now as formerly.

The first point worthy of attention upon examination of the external genitals is that the vulva, perineum, and buttocks are excoriated by the discharge, which is manifestly of a very irritating nature. Spreading open the labia, there is revealed an intensely red, swollen, and ulcerating surface, which involves the meatus urinarius and extends upward to the clitoris; by depressing the perineum the anterior vaginal wall is exposed for a short distance, and the ulcerated surface can be seen extending inward in the line of the urethra. Digital examination reveals a still further internal extension, and along the whole length of the urethra to the base of the bladder the deeper tissues are firm, hard, and resistant. The raw surface bleeds freely when touched, and you can see that the pressure on the urethra causes a thin purulent discharge to issue from the meatus. The cervix uteri is almost beyond reach, far back in the sacrum, but feels natural; with which information in regard to it we will be content, as there would probably be no further light shed on the nature of the case by a specular examination at this time, and because the vagina being so narrow, the tissues so tense, and the raw, ulcerating surface so sensitive, an instrumental examination would be excruciatingly painful.

The nature of this growth is almost positively either epitheliomatous or carcinomatous, but there is just enough doubt to render a microscopic examination of the diseased tissue desirable; so I will remove a small fragment with the scissors, and have it submitted to the pathologist of the hospital for his opinion.

If this is a carcinoma, what can be done for the patient? The location and extent of the trouble is such that I am inclined to think there is but little hope of benefit from any operative procedures for its extirpation. The most feasible and reasonable treatment will be to relieve her suffering, which is almost wholly due to the act of urination, by making a button-hole opening into the bladder from the vagina and maintaining a permanent fistula there.

Should this prove to be a localized manifestation of tuberculosis—and such a thing is barely possible—the treatment will be to curette or dissect out as much of the diseased tissue as is possible, and to apply some such local escharotic as lactic acid.

CLINICAL MEMORANDA.

A CASE OF SUDDEN DEAFNESS FROM INHERITED SYPHILIS.

By ROBERT BARCLAY, A.M., M.D.,
FORMERLY ASSISTANT AURAL SURGEON TO THE NEW YORK EYE AND EAR INFIRMARY; AURAL SURGEON TO THE CITY HOSPITAL, ST. MARY'S HOSPITAL, MISSOURI BAPTIST SANITARIUM, HENRIETTA STREET HOSPITAL, HOUSE OF THE GOOD SHEPHERD, ETC.,
ST. LOUIS, MO.

If we may judge from published reports, a morbid condition very rarely met with, even in special otologic practice, is that of sudden deafness from inherited syphilis. The case of which the history is here cited is instructive in salient features not exclusively otologic, and may prove not without interest to the numerous readers of The Medical News:

Case 3826.—The patient is a girl, twelve years old, of blonde complexion, apparently in perfect general health. Her twin-brother died two or three weeks after birth "of brain-fever." (?) She "has had all children's diseases." At the age of eight years she had eye-disease, but of what nature or character cannot now be ascertained. Of this she was entirely relieved by treatment while at Hot Springs, Ark., whither she had accompanied her invalid mother.

For one year past she has been under the care of another physician for slight deafness. For a portion of last summer, it is said, she was very deaf. Two weeks ago she suddenly, and for all practical purposes, wholly lost her hearing. The deafness is so profound that shouting into the auricle is heard on the left side only, and there as noise which is unintelligible; while there remains in the left ear only hearing, slight at best, for the middle C tuning-fork. The patient can hear her own voice when speaking. On examination, the drum-heads are found a trifle duller than normal, more opaque and lusterless, and the handle of the malleus retracted. All four second molar teeth are simultaneously cutting through the gums. Inflation of the tympana has no effect whatever upon the hearing. An expert opinion as to the appearances of the teeth was secured from Dr. George A. Bowman, the dental surgeon, who examined her by special request. He prepared a plaster cast of the mouth, which is now in possession of the writer. Dr. Bowman reports: "Here is a reproduction of the mouth of . . . with *Hutchinson teeth*, unmistakable! She is an innocent victim of ancestral taint. . . . You see a tooth missing on the left *lower* jaw—never emerged through the gum. You will notice that the molars are dwarfed."

Interrogating the parents separately elicited the fact that the mother has been a sufferer from rheumatism for many years, and that she was treated for it at Hot Springs, Ark., eight and again three years ago. Of her children, the first one died sixteen days after birth, "of hives." (?) Then she had an abortion at the third month of pregnancy. The second child, twin-brother of the patient, died in the second or third week after birth, "of brain-fever." The third lived two months and four days. She then aborted twice successively, at about the third month of pregnancy. The fourth child died six days after birth. The fifth, now living, was born three

years ago; and the mother has not conceived since. The father confesses that he contracted syphilis "many years ago." The family physician as well informs me that the mother, without a knowledge of the nature of her affection, has been treated by him for manifestations of syphilis.

There seems to be a reasonable probability of the correctness of the diagnosis of deafness from inherited syphilis, and the prognosis was pronounced unfavorable.

To complete the history, it may be stated that all therapeutic attempts, though reasonably varied, to relieve the deafness, are of no avail whatever.

Remarks.—Among the many instructive features of the case, it may be remarked that the disease developed, as usual, a short time before puberty; that there was a predisposing local inflammatory condition—chronic catarrh of the ear; and that there was a distinct exciting factor—reflex aural irritation from eruption of the four second molar teeth simultaneously. Thus the *raison d'être* of the *aural* syphilis seems established. The fact that tissue-conduction of tuning-fork sonorous vibrations, and of those of her own voice, gave the patient sensations of sound in the left ear, proves that there remained intact within its labyrinth and auditory nervous system an apparatus for the transformation of tissue into nervous vibrations, and for their transmission to the sensorium.[1]

It is interesting to note the specific phenomena on the maternal side: rheumatism, three abortions at about the third month, the early death of four of her offspring,[2] and unfruitfulness. The death of the first child, sixteen days after birth, "of hives" (?) may be considered an example of the early and peculiar mortality of hereditary syphilis. It will be remembered, in this connection, that, as Dr. Taylor puts it: "In some cases, soon after birth syphilitic lesions are seen in the infant. The most precocious evidence of hereditary syphilis is the bullous eruption, and it is always the expression of profound systemic poisoning."[3] "The onus of hereditary transmission of syphilis is necessarily thrown upon the *mother*"[4] in this case, as well as upon the father; but whether it is always upon the mother only, authorities, especially Drs. Otis and Taylor, differ.[5]

In conclusion, we may remark the suddenness, the profundity, and the hopelessness of this affliction which hovers threateningly over the little child of syphilitic parents.

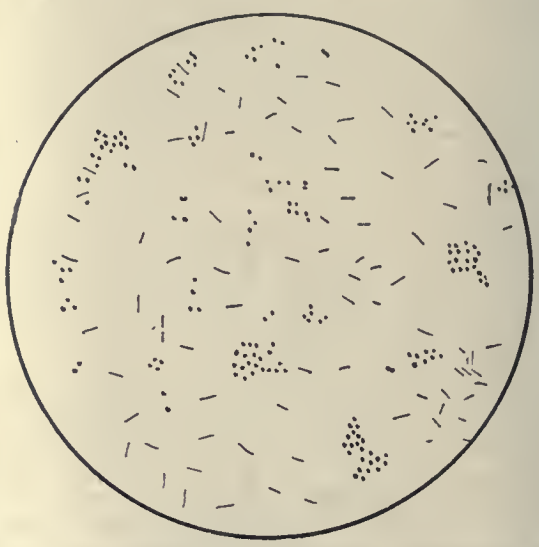
GANGRENE OF THE TESTICLE.

By D. BEVAN, M.D.,
Assistant, Department of Hygiene, Jefferson Medical College, Philadelphia.

On February 18, 1891, a young man was brought into the hospital in an unconscious condition. The resident discovered a tumor in the right inguinal region, which on percussion was tympanitic. When restored to consciousness the following meager and incomplete history was obtained: His mother had died of heart-disease twenty years ago. His father is living and believed to have always been healthy. The patient has suffered from birth with hernia, which was reducible, and an undescended testicle that at times protruded from the external ring. The present attack began Sunday last with vomiting, which ceased toward evening and has not recurred. On Monday his bowels became very costive, and he asserted that there was a palpable increase of the swelling in the right inguinal region. He attempted to replace the bowel, as he had previously done when it descended, but found that this was now impossible. He experienced considerable pain in and extending from the tumor toward the umbilicus. An impulse was transmitted on coughing.

Professor Keen removed the testicle; before which time, however, Professor Brinton, upon the invitation of Professor Keen, attempted to reduce the hernia, in which he evidently succeeded, for, upon cutting down upon the part, no gut was found in the canal. Professor Keen clearly demonstrated the cause of gangrene. The cord was twisted, having one whole twist and a half, thus almost if not absolutely cutting off the blood-supply to the organ.

Immediately after the clinic I made an examination of the testicle. The gangrene was evidently extending, and in a short time would probably have involved the whole organ. The posterior, and especially the lower



Cocci and bacilli observed in the blood obtained from the vessels of the epididymis. Agar-agar culture, Gram's method, Beck's $\frac{1}{12}$ homo. im., Oc. 2. Camera lucida drawing.

portion, was found to be in an advanced gangrenous condition. Upon puncturing the testicle posteriorly with a sterilized needle, it was observed that the parenchyma was exceedingly soft and granular, having been broken down and destroyed either directly by the microbes or indirectly through interference with its blood-supply. There were also large clots in the veins. The connective tissue had not as yet succumbed to the pathologic process, and contained in its meshes the degenerated

cells referred to. Upon withdrawing the needle, there oozed out a little thin and blackish fluid. Cover-glass impressions were made and tubes inoculated. The cover-glass films were treated with acetic acid and stained, by a rapid method, with methyl-violet. Examining these slides with a microscope, I found innumerable cocci and bacilli to be present. The thrombi in the veins were infected, as proved by stains made from the removed coagula. Although attempts were made to secure cultures from the infected organ, no growths could be obtained; presumably the antiseptic used in the operation had destroyed their vitality. In sections of the organ no germs were present in the parenchyma, but the clots in the vessels of the epididymis contained innumerable bacteria.

There was reported in one of the last fall numbers of the *Archives de Médecine Expérimentale et d'Anatomie Pathologique* a very interesting series of experiments, made in one of the French laboratories, of the process of infection that occurred in hernia. I am at present unable to find this article, or to even give the number in which the article appeared. It was accompanied by cuts showing the different microörganisms found and their genetic significance. Most important among these was a small bacillus and a coccus, resembling though not identical with some of the cocci of suppuration. The two organisms had been isolated from gangrenous intestines, the result of strangulation, in the human subject. They had also been demonstrated as being the saprophytes of the intestine, and only springing into action when the intestine was subject to unfavorable conditions affecting materially its circulation or obstructing the flow of its contents. The method by which infection occurred was presumed to be as follows: When the lumen of the intestine had become occluded, permitting the production of ptomaïnes in large amount, this led to inflammation, which afforded a suitable nidus for infiltration of the saprophytes. The bacillus seemed more active than the coccus, and could be found not only in the gangrenous bowel, but in the fluid contained in the hernial sac. The cocci were found only in the walls of the sloughing tissue. With these experiments borne distinctly in mind, we are able to arrive at a more definite idea of the method by which infection at this place in the testicle occurred. There had been a hernia, which evidently had not become gangrenous itself, but on account of the strangulation to which it had been subjected, the microörganisms had penetrated its walls and thus infected the vessels of the epididymis. The bacilli are supposed to be active in the production of gas, and some observers ascribe to the cocci the power of engendering gangrene; while this may be true, the writer is of the opinion that in this case at least the disintegration is attributable to the twisting of the cord, thereby obliterating the lumen of the vessels and cutting off the blood-supply.

A CASE OF ACUTE GENERAL CHOREA.

By J. T. BRINGIER, M.D.,
of Bubnside, La.

Dennis E., a colored laborer, nineteen years old, of good habits, was suddenly seized, on March 19th, with violent uncontrollable clonic convulsions, in which the facial muscles and the tongue participated, so that the face was distorted and speech was scarcely possible. I had treated him a month previously in an attack of influenza. In the meantime he had had an attack of mumps. The family of the patient ascribed his condition to the repeated taking, for several days, of copious draughts ot gin, containing a small quantity of quinine. The man was of temperate habits and not accustomed to alcoholic stimulants. It was not possible to take the patient's temperature on my first visit, but I think that it was above normal. He complained of headache and tinnitus aurium and pain in the back. Although the patient comprehended my inquiries, I could learn little from him, because of the difficulty of speech. He was given a full dose of magnesium sulphate at once, followed by the bromides and chloral in combination. The latter was repeatedly rejected. Hyoscyamine, grain $\frac{1}{30}$, was exhibited as a substitute, with satisfactory results.

On the morning of the 20th the patient was quieter, though he had not slept well during the night. The temperature was 102.4°; the pulse, 124. The mental faculties were perfectly clear. The muscular twitchings were apparent about the face and arms, but the lower extremities were motionless. The man had taken food by the mouth, and in reply to my query stated that he was feeling much better. The hyoscyamine was continued, and a fever-mixture containing tincture of aconite, morphine acetate, and spirit of nitrous ether was ordered to be given as needed.

On the 21st the condition of the man was still more favorable. He had slept well during the preceding night. The appetite was good; the temperature, 101.6°; the pulse, 116.

On the 22d the choreic movements were much aggravated; the temperature, 102.4°; the pulse, 134. Unable to account for the rise in temperature, I made a careful examination and found one testicle much enlarged and painful to touch. I now first learned that the patient had had mumps. Metastasis at once suggested itself, with the possibility that the symptoms were reflex. It was elicited that the orchitis had existed from the onset of the attack, but was thought to be of no special consequence. The organ was elevated, and cold applied.

The supply of hyoscyamine having been exhausted, full doses of phenacetin were given instead; and for the sleeplessness, thirty grains of sulphonal were administered at dusk.

On the morning of the 23d the choreic movements were worse than at any time previously. The patient had tossed violently throughout the night. Mattresses were placed on the floor, and though he was much weakened by continued fever, loss of sleep, and violent exertion, it required the aid of three men to permit the subcutaneous injection of morphine sulphate, grain $\frac{1}{4}$, atropine sulphate, grain $\frac{1}{120}$. The injection was twice repeated during the day, plus half a grain of morphine by the mouth, but without any appreciable effect. Forty grains of sulphonal were given at bedtime, but without avail.

On the 24th, despite the violent struggles, the orchitis and the fever had materially subsided. The man was weaker; otherwise his condition was unchanged. At noon he was given hyoscine hydrobromate, grain $\frac{1}{100}$. Four hours later the dose was repeated. After the second dose the patient became calm, and a refreshing

sleep of ten hours' duration followed. Two doses of hyoscine were given on the 25th, two on the 26th, and but once each on the 27th and 28th. There has scarcely been a muscular twitch discernible since the 25th. On the second day of the attack five minims of the officinal solution of potassium arsenite were administered three times a day; the dose was gradually increased to ten minims. On April 7th all symptoms of chorea had disappeared, and the general condition of the patient was so much improved that he resumed work.

I have reported this case to contrast it with that reported by Dr. George A. Himmelsbach, in THE MEDICAL NEWS of March 12th ("An Aggravated Case of Chorea"), in which hyoscine failed utterly to give relief, and morphine proved efficient. Thus we see how futile it is to pin one's faith upon the effects of any one drug.

RETROVERSION OF THE GRAVID UTERUS IN A PRIMIPARA.

BY E. M. ALBERS, M.D., AND H. S. RAWLINGS, M.D.,
OF VICTORIA, TEXAS.

ON September 13, 1891, Dr. Albers was called to see J. S., a colored primipara, unmarried, seventeen years old. She had menstruated for the last time on about the first of May. For two months the abdomen had been enlarged, and for several weeks there had been a gradually progressive impediment to micturition and defecation. Upon inspection, a large semi-solid or fluid abdominal tumor was found extending up to or a little above the umbilicus, suggestive of a six or seven months' pregnancy, manipulation of or pressure upon which caused pain. Upon separating the labia majora a tumor was detected, presenting a cone-like termination, with an excavation in its center. The finger could be introduced between the tumor and the anterior wall of the vagina up to the symphysis. Diligent search failed to reveal the cervix. On combined rectal and vaginal examination, a tumor was found filling up the pelvic cavity, the lower part of the tumor pressing on the perineum, the upper part being beyond the reach of the finger. A catheter was introduced into the bladder, and about three or four quarts of urine withdrawn. There was no diminution in the size of the abdominal tumor, which remained as tense and unyielding as it had been. The patient was exceedingly sensitive to any pressure over the region of the abdominal tumor. No action of the bowels could now be obtained, and retention of urine necessitated the use of the catheter. The mammary areolæ were darker in color than the surrounding skin, and a drop of milk was squeezed from the breast.

The family objected to any operation, exploratory or otherwise, seemingly satisfied to let the girl die. On September 16th the patient was evidently sinking. An incision, about half an inch in length, was made in the highly congested mucous membrane of the vagina, and the engorgement was soon relieved. At once slight contractions of the vaginal tumor became manifest; and three or four hours later the girl was delivered of a fetus at about the fourth month of gestation, dying an hour later. On the following morning a post-mortem examination was made. The tumor was bound to the abdominal walls by firm adhesions. The mass proved to be the bladder, the walls of which were enormously hypertrophied. The uterus completely filled the pelvic cavity, the fundus resting on the perineum, the cervix up behind the symphysis.

The condition of the bladder accounted for the fact that the tumor did not diminish in size when the catheter was used and the cavity emptied.

NOTE ON EXCISION OF THE ELBOW.

BY WILLIAM HUNT, M.D.,
OF PHILADELPHIA.

I RISK being called an old fogy by recording the following observations. I have always been skeptical about the expediency of removing the elbow-joint for acute injury. Of course, the case might be such as unquestionably to require the operation; but such cases are rare. The strength and usefulness of the limb are much better preserved by obtaining ankylosis, say at 60 degrees, than by the flail-like union that follows excision; and if the radial movements are preserved, almost perfect use, except extension, is obtained. These remarks are founded on two cases observed through years, and my unrecorded recollections of many other cases bear out the same ideas.

Fifteen years ago a very noted and bold woman, a flying-trapeze performer, fell at one of our theaters. It was found that she had sustained a compound, comminuted fracture of the left elbow. The patient came into my wards at the Pennsylvania Hospital. The injuries were so profound as on consultation to give rise to the questions of immediate amputation or excision. The decision was with me, and I determined to pursue the conservative course. I placed the limb on a pillow in the angular position, used various dressings in the progress of the case, and removed dead fragments of bone as they presented themselves. The woman got well with ankylosis. She was wonderfully plucky, and immediately set about gaining her living in her old haunts. Last week she called on me. She said her object was to see me and renew her thanks, for she had promised herself that she would do so when she came to Philadelphia. Her particular object, besides this, was to invite me to the Dime Museum to see her perform and use her left hand.

I went; and truly her acting was wonderful: she spun and rolled and tossed all sorts of objects, balanced tables and barrels on her chin and on her feet, and in her hands, and altogether was as fine a performer in that particular line as I ever saw, or as one would wish to see. Her arms were bare to above the elbows, and I doubt whether a single person in the large audience, not acquainted with the facts, knew or suspected that there was anything the matter with her left elbow-joint. The acts also showed how few really useful or necessary movements are performed with the upper extremity in the position of extension.

It must also have been about fifteen years ago that two patients, both men, came into the Pennsylvania Hospital with compound comminuted fractures of the elbow. One fell under the care of my colleague at that time, the late lamented Dr. Richard J. Levis. He was progressive, as we all know, and promptly excised the joint of his patient, whose occupation I do not know. My man was a fireman who had sustained a very severe injury, much

worse than the other. To give an idea of it, the whole olecranon was thrown out posteriorly through a skin-laceration, and was twisted completely on its axis, so that the articular surfaces presented backward. Under ether I reduced the luxations and dressed and treated the parts as I did in the woman's case.

Both of the men recovered, and I now had an opportunity of observing them, which I did for years after. The usefulness and strength of the limbs were incomparably in favor of my patient. He returned to service in the same fire company, and may be there yet. The efforts of the other man to do any useful act with his flail-like limb were really painful to look at. The amount of bone removed by the surgeon was so great that I doubt whether the man could pursue any useful occupation for any length of time.

My advice, therefore, is for surgeons to look and think twice before they excise an acutely injured elbow-joint.

HYDRARTHROSIS OF THE KNEE-JOINT; PARACENTESIS; IRRIGATION; RECOVERY.

By W. D. JONES, M.D.,
of Rising City, Neb.

H. A., a German, thirty-two years old, of good general health, presented himself November 9, 1891, with enlargement, stiffness, and pain at the left knee-joint. About seven weeks previously, while working in the field, the outer portion of the capsule of the joint was perforated by a pitchfork in the hands of a careless fellow-laborer. The injury was followed by continuous pain and gradual and increased swelling of the joint. The circumference of the knee was twenty inches; the skin was tense and glistening, and traversed by numerous enlarged bloodvessels.

Paracentesis of the joint was antiseptically performed, and nine ounces of thin, greenish, sero-fibrinous synovial fluid removed, becoming gelatinous upon cooling. Inunctions of mercury oleate were prescribed, to be used once daily until active vesication occurred. A rubber bandage was applied, and the leg was put upon a posterior splint, with an ice-bag to the knee for twenty-four hours.

Ten days later the joint had again filled. Paracentesis was a second time antiseptically performed. The joint-cavity was irrigated with warm Thiersch's solution (salicylic acid 2 parts, boric acid 12 parts, hot water 1000 parts) until the fluid came away clear; the joint was then flushed with a 1 per cent. solution of carbolic acid; the joint was immobilized by a posterior splint, the rubber bandage and ice-bag applied as before, and the patient put to bed for a week, after which passive movement of the joint was practised once daily. The patient was allowed to take moderate exercise with the fixation-splint *in situ*. The splint was continued until the patient was dismissed, January 13, 1882.

There was then a small amount of fluid to be detected in the joint. Extension was perfect; flexion was but slightly impaired. The thickening of the capsule and of the cartilages of the joint have been gradually disappearing under the influence of massage and inunctions of mercury oleate.

MEDICAL PROGRESS.

Hysterectomy for Carcinoma of the Uterus.—Braithwaite (*British Medical Journal*, No. 1624, p. 329) reports the results in twelve cases of carcinoma of the uterus treated by complete vaginal hysterectomy and in four treated by supra-vaginal hysterectomy. Of the first group, three were living and free from recurrence of the disease at the time of report, four years, eighteen months, and ten months, respectively, after operation; one was living, free from disease, four and a half years after operation, but had been lost to observation for a year and a half; one died two years after operation, without recurrence of the disease; in two cases the uterus was profoundly involved, and death followed the operation in six months and a few months, respectively; in four cases there was fatal recurrence: four months, three months, ten weeks, and soon, respectively, after operation; one case died from acute suppurative peritonitis following the operation. Of the four cases in which supra-vaginal hysterectomy was performed, one was free from recurrence nearly five years after the operation; in two the disease recurred in seven months and two months, respectively; one case died twelve hours after the operation from shock and hemorrhage.

Transperitoneal Nephrectomy.—Heinricius (*Centralbl. f. Chirurgie*, 1892, No. 14, p. 297) reports the case of a woman, twenty-seven years old, who presented an abdominal tumor below and to the left of the umbilicus. The swelling had first been observed two years previously, when it was as large as a fist. It had subsequently increased in size, but for a year its growth had ceased. The tumor was tense and mobile. Over it, and in the left lumbar region, the percussion-note was dull. The position of the uterus was normal. On vaginal and rectal examination no connection between the tumor and the internal genitalia could be detected. The urine was clear, of a specific gravity of 1015, and contained no albumin. A diagnosis of hydronephrosis was made, and celiotomy decided upon. The colon was displaced from in front of the tumor, the peritoneum incised, and the cyst punctured. The ureter and the pedicle of the mass were secured by several double ligatures, and the kidney was removed. No cause for the abnormal condition could be found. After the operation, the quantity of urine passed gradually increased, until it reached the normal. The patient ultimately recovered.

Periodic Nocturnal Cough in Infants.—Baginsky (*Traité des Maladies des Enfants*) describes in infants a periodic nocturnal cough of obscure origin. Without apparent cause, the child is suddenly awakened during the night by violent cough, lasting from fifteen minutes to half an hour. At the conclusion of the paroxysm the infant goes to sleep again, and in the morning is bright and cheerful. Ordinarily, physical examination discloses nothing abnormal. The attacks have been ascribed to malaria, but frequently such an origin can be excluded. Most probably the condition at fault is a subacute or chronic rhino-pharyngitis, with swelling and secretion, or a bronchial catarrh, with hyperesthesia of the mucous membrane of the respiratory tract, the accumulation of mucus during sleep by irritation inducing the paroxysm.

It is thus that expectorants afford relief. In cases of malarial origin quinine is indicated. In obstinate cases small doses of morphine may be required.—*Journ. de Méd. et de Chir. prat.*, 1892, lxiii, 5, p. 192.

The Reaction of Urine with Ether.—ANDREW H. SMITH (*Lancet*, No. 3578, p. 688) has found that if urine be shaken with half its bulk of pure sulphuric ether, in most instances a gelatinous layer collects on the surface. The reaction occurs with urine that does not contain albumin or peptones, and with urine from which the phosphates have been removed. It does not occur with simple solutions of urea or of urates. From the fact that the reaction is most decided with the urine of persons of good appetite and digestion, and is usually absent after fasting or when the diet is restricted, it is thought to be indicative of an excess of nutritive material taken into the blood and excreted by the kidneys. The nature of the substance on which the reaction depends has not yet been determined, but it is thought probable that the occurrence of anuria in the course of prolonged etherization is owing to the development of the reaction in the parenchyma of the kidney.

Hydatid Cyst of the Anterior Abdominal Wall.—TREUBERG (*Deutsche medicin. Wochenschr.*, 1892, No. 14, p. 308) has reported the case of a woman, fifty years old, who, three years previously, had observed in the anterior abdominal wall, in a situation corresponding with the right iliac fossa, a small, hard tumor, of the size of a hazelnut, that at first caused no pain, but subsequently became extremely sensitive. In the previous month the swelling had become much larger and the pain more intense. The tumor was hard and moved with the abdominal wall, but it could not be determined whether it was situated above or beneath the muscular layer. It was thought to be a fibroma, and its removal was decided upon. The mass proved to be an echinococcus cyst, situated beneath the superficial fascia, as large as a goose-egg, with clear, watery contents, a lamellated capsule, and a number of translucent daughter-cysts, varying in size from that of a pinhead to that of a pea.

Myomotomy During Pregnancy.—FLAISCHLEN (*Centralbl. f. Gynäkol.*, 1892, No. 10, p. 185) has reported the case of a primigravida, thirty-two years old, in whom, in the third month of pregnancy, a firm, nodulated, movable mass, as large as a child's head, and of rapid growth, was, on examination, detected behind and attached to the uterus. Malignant disease of the ovary being suspected, celiotomy was performed and two fibromata were found, one pedunculated, the other attached to the uterus by a broad base. The growths were removed and the wounds sutured. The pregnancy progressed without interruption and at term the patient was naturally delivered of a healthy child.

Some Dangers of Lavage.—FENWICK (*Practitioner*, 1892, xlviii, 4) condemns the indiscriminate employment of lavage in every disorder of digestion, pointing out numerous complications to which the procedure may give rise. Thus there may result convulsions, tetany, syncope, and sudden death. In a case of latent ulceration, the walls of the stomach may be perforated. Hemorrhage sometimes results when there is no ulceration. The use of any but a soft-rubber tube may be attended with injury to the gastric mucous membrane. When antiseptic solutions are employed, the possibility of intoxication should be borne in mind.

THERAPEUTIC NOTES.

Conjoined Employment of Tuberculin and Tuberculocidin.—In a number of cases of advanced pulmonary tuberculosis treated by means of tuberculocidin, SPENGLER (*Deutsche medicin. Wochenschr.*, 1892, No. 14, p. 305) observed that dyspnea was relieved, hectic fever disappeared, and the pulse became regular, when the symptoms were related to the tuberculous affection. He failed, however, to observe the destructive changes so evident in superficial tuberculosis after injections of tuberculin, and which he attributes to a specific, local exudative inflammation. With the view of obtaining this specific action, together with the transudation destructive of the bacilli, ascribed by Klebs to tuberculocidin, Spengler employed injections of tuberculocidin in conjunction with injections of tuberculin. By careful dosage he succeeded, in a limited number of cases, in obtaining marvellously good results. The initial dose was from five (0.005) to twenty (0.02) milligrams of tuberculocidin, administered almost daily for a month or more, and gradually increased to from three hundred (0.3) to five hundred (0.5) milligrams; and from one-fiftieth (0.00002) to one-tenth of a milligram (0.0001) of tuberculin, administered at intervals of from one to four days, and increased to from three-tenths (0.0003) to four-fifths of a milligram (0.0008).

Solanine in Affections of the Stomach.—At a meeting of the French Academy of Medicine, DESNOS (*La Médecine Moderne*, No. 12, 1892, p. 175) reported the employment of solanine, in daily doses of from three-quarters of a grain to a grain and a half or more, in seventeen cases of painful affections of the stomach, in but four of which without success. Solanine is obtained from potatoes, and especially resides in the peel. It acts on the cord, the medulla, and the peripheral nerves, occasioning marked anesthesia. The remedy is indicated for tremor and for painful conditions.

THE MANAGEMENT OF FEVER.

THE vast majority of the acute diseases coming under the observation of the physician are of a febrile character, and the physician who understands well the management of fever possesses a knowledge and skill most important to his patients.

By the management of fever, we mean, as a matter of course, the management of patients with fever, and in all that is said, due allowance must be made for individual conditions and susceptibilities.

The greatest mistake that the medical attendant of a fever-patient can make, is to treat temperature. Pyrexia is but one element in the syndrome-group of the febrile process. Perversion of metabolism, diminution and arrest of secretions and excretions, are, if less obvious, equally important phenomena.

HIPPOCRATES may not have been the first to observe that the heat-phenomena of fever were often indications of Nature's method of battling with an enemy, yet the antiquity of this teaching is sufficiently evident if we give it only its common name of the Hippocratic doctrine. Not all that is old is true, as not all that is new is good, but the truth of the Hippocratic doctrine of the frequently conservative tendencies of fever-heat is becoming more and more apparent, as scientific observation in medicine replaces hap-hazard empiricism and novelty-seeking.

Nothing has so forcibly emphasized the value of this doctrine as the results of the antipyretic medication that came into such wide and unfortunate vogue with the perfection of chemical processes leading to the manufacture of kairin, antipyrin, and the other powerfully poisonous coal-tar derivatives. Even those who a few years ago most strenuously advocated the use of these agents to reduce temperature in typhoid fever and pneumonia now teach that such treatment is inefficient, though too few have had the courage to say that it is dangerous—in some cases, probably murderous. It depresses not only heat-production, but also respiration, circulation, excretion, and the functions of organic life in general. It adds drug-poisoning to disease-poisoning. Vigorous is the patient who can survive both.

Unfortunately, falsehood speeds faster than truth can overtake. The whilom honest but mistaken teaching of a few men deservedly eminent in the profession, and its blatant echoing by the host of imitators eager to gain notoriety by proclaiming from the housetops the latest novelty, have had the effect of popularizing the method of reducing temperature by powerful drugs. The fact, too, that a symptom alarming—needlessly alarming—to the friends of the patient can often be rapidly, apparently magically, made to disappear, has not been without effect in the curious complex of motives influencing the commercial medicine-man. Thus, alike those who look to the colleges and hospitals for guidance and assistance in earnest endeavors to do good to their patients; and those who seek agents of striking power in order by the impression produced to do good to themselves, have become so accustomed to give drugs to patients exhibiting high temperatures, that it is a difficult matter to bring about a return to more rational methods. Fortunately there is an indication that the novelty-seekers are about to make a fad of the cold-water treatment of typhoid fever. Though this is novel only to them, it is devoutly to be hoped that they will succeed in popularizing it. The courage and devotion of BRAND to what he knew to be right, his persistence in the face of opposition and ridicule, and despite honest criticism evoked by the blunders of timid and half-hearted followers that "would like to bathe patients without wetting them," are examples of virtues too rare in the history of medicine. Bathing reduces temperature,

it is true; but it does so by stimulating and supplementing the natural processes of thermolysis and excretion, and not by depressing normal thermogenesis. Sponging will not replace it; for there is an abstraction of abnormal heat and a soothing of abnormal nervous irritation brought about by immersion in a large volume of water, that cannot be brought about in any other manner. It has been said that there is a salutary pyrexia as well as a dangerous hyperpyrexia. These cannot be separated by an arbitrary line; but the rule of BRAND to keep the temperature of typhoid-fever patients below 102.4° F. has the good results of more than thirty years' consistent practice in its favor; the method of effecting this, it is to be remembered, being by the cold bath, not by depressing drugs; and the indication itself being derived from observation of the effect of the treatment by cold-bathing. BRAND is careful to insist that the temperature is regarded by him only as an index, and that his method of treatment combats fever—the morbid complexus, not pyrexia—the symptom.

Not less important is it to give febrile patients comparatively large draughts of water. The trained nurse does not appreciate this, though the physician may. Again and again have we been answered, "He didn't ask for it," or "All he asked for," in reply to inquiries as to the amount of water the patient was drinking. Nurses must be told to give definite quantities of water at definite intervals. Water accomplishes two desirable ends—it dilutes the poisons that enter the circulation as a result of perverted metabolism, and it mechanically facilitates the excretion of useless or toxic katabolins by the kidneys and the skin.

Diarrhea, if not excessive, is better than constipation for a patient sick with fever. In the absence of counter-indication, the bowels should be evacuated, *i. e.*, properly emptied, daily—whether spontaneously, by drug, or by enema. Diarrhea is not always a counter-indication to the administration of a suitable purge or the use of an enema; it may even indicate the necessity for such measures, for frequent ineffective efforts of the bowel to empty itself of irritative and toxic matters may be checked by removing the cause.

If a patient with fever be kept at rest, clean, plentifully supplied with fresh air, pure cold water, and small quantities of easily digested food; if his emunctories be maintained in a condition of gentle activity; if cold water be used externally in a proper manner, and when indicated; if alcohol be avoided unless definite indications for its use are present, the question of drug-giving will become subsidiary, and the nature of the medication, whether antiseptic, supporting, specific, sedative, or whatever else it may be, will necessarily vary with the etiology of the affection, the mechanical and pathologic conditions present, and the constitution or present status of the individual patient.

SNEAK-ADVERTISEMENTS.

OUR request for evidences of the work of the surreptitious advertisers has brought us unexpectedly large and highly interesting proofs of the extent to which this practice obtains. The suggestion occurs that if some extremely cute fellow would "work" this vein in a purely business way he might make a snug fortune out of the ambitious doctor by getting a few—a very few—data directly, and then doing all the rest of the business, reportorial, typographic, and ethical, himself. It may, indeed, be that such an institution is in full working-order (only men of a certain class would know of it, of course), with agents in the different cities. The duplication of despatches in different newspapers would suggest a unity of cause, quite as much as the editorial assurances, all identical in a hundred journals, concerning the "member of the amido-benzole series." These go to show that medical editors occasionally have so marvellous a unanimity of opinion that it extends to reproduction and "unconscious cerebration" of several pages of words alike in all, even down to a comma. Now, the agent of the sneak-advertisers must learn better than this, which, to a brother editor forced to glean the medical literature of the day, becomes not only stupid and repetitively tiresome, but disgustingly unimaginative. It seems to him much like "patent insides," or "patent outsides," and looks toward the final consummation of an ideal state in which the patent-medicine syndicates and secret-nostrum venders should in one city stereotype the highly scientific contributions of the medical writers employed by the stockholders, and send the printed pages to the local agents of THE MODERN DOCTOR UP TO DATE, for pseudo-issuance by them. In this way the medical editor would be freed from editorial work entirely, and he could get all the honor, and more of the profit, by thus loaning his name and auctioneering HYGEIA to the medical mob.

We have no present intention of uncovering the Pandora-box in which the modest hobgoblins of our scrap-book try to hide. We only wished to notify some of our kind correspondents that it is only the sly dodges of the regular physician—that is "in good standing," "a member of such and such reputable medical societies, etc.," that we wish to obtain proofs of. For obvious reasons, we have now nothing to do with the out-and-out quacks. Their affair must be settled by legislation of the whole country. They have the merit of frankness and of what the prize-fighters would call courage. It is the double-faced fellows we are after—those who secretly import into medicine the morals and practices of the ward politician, whilst pretending to belong to a craft that detests such actions. Will not correspondents also give the date and the name of journal from which the scraps are taken?

THE SAMUEL D. GROSS MONUMENT FUND.

In another column will be found a circular issued by the committee appointed by the American Surgical Association to secure funds for the erection of a monument to Samuel David Gross. Utilitarians may object that a pathologic laboratory or other medical foundation would be a more fitting memorial to such a man than sculptured brass can be. Those who know what inspiration there was in his living presence, even though he opened not his lips, will not share so narrow a view. Let all who tread the streets of the Capital City see reproduced in enduring bronze the noble figure and the finely chiselled face, and ask, "Who was this man?" Let them be told, "It is he who re-created American medical literature, who made American surgery famous, and American medical teaching fruitful; who won from the Old World honor for the science and learning of the physicians of the New World; and who taught his pupils not alone the arts, but the dignity of their profession."

Let them learn of his life and his work and let them thus learn what it means to be a true physician. And let us, too, of the profession he loved, draw comfort and inspiration from the sight. Especially in these latter days of respectable quackery, let the Gross Monument mutely tell all who enter the ranks of medicine that lofty ideals will lead to the highest success, and that one need not sully his conscience to win the rewards that the community and the profession richly shower upon those who prove in all things deserving.

SELECTION.

REGULATION OF DISPENSARY PRACTICE.

This subject has received considerable editorial attention from the *Lancet-Clinic*, and were it not for a step which has been taken toward the solution of the question, we would feel much hesitancy in again bringing this subject before our readers. Serious consideration devoted to this subject is time well spent, because the evil is constantly growing, and each year assumes a more threatening aspect. Something must be done to regulate this business or there will be a deep, yawning chasm full of bad feeling existing between the profession at large and the medical colleges. The arguments in favor of some regulation are so well known that a repetition is superfluous.

By chance we heard the other day that the Ophthalmic Hospital had taken a step in this matter, and in order to satisfy ourselves we obtained the following slip, which explains itself:

Ophthalmic Hospital and Dispensary, Cincinnati, O.

It has been suggested that you are not a proper subject for treatment in this hospital. This institution is for those in poverty and distress *only*, and it will be necessary for you to furnish evidence on this blank from some responsible party that you are a proper person for the recipiency of its charity.

(Signed) ————————

Executive Officer, Ophthalmic Hospital.

Date, ————, 189—.

————— is known to me to be worthy of the charity offered by the above institution.

(Signed) ————————

It seems to us that this is a long step in advance, and one that might be adopted by all the dispensaries without detriment to their attendance, but with decided benefit to the medical profession in general.

In fact, we believe the medical men of the city have a right to demand that some such step be taken by all medical institutions which treat patients free of charge. Promiscuous charity is unjust, unwise, and injurious; it gives rise to imposition, dishonesty, and fraud; therefore, the dispensaries should see to it that, so far as possible, none but the poor receive gratuitous medical attention.

The plan outlined above has the merit of simplicity, and yet it is effectual. The slips can readily be kept on file for future reference, and thus become permanent records. No deserving person need be without medical attention, and yet the medical profession can protect itself against fraud and deception.

In order to render the plan as successful as possible, it is necessary for all dispensaries to adopt the same plan and coöperate in the matter. Thus may we stamp out the most gigantic evil connected with medical practice.—*The Cincinnati Lancet-Clinic.*

A New Italian Pharmacopeia has just been completed.

HISTORICAL.

FOUR LETTERS OF DR. BENJAMIN RUSH.

(*Presented by* GUY HINSDALE, M.D., *to the College of Physicians of Philadelphia.*)

VERY few original letters by Dr. Benjamin Rush are extant, excepting among the Rush memorials preserved in the Ridgway Branch of the Philadelphia Library. The College of Physicians, of which he was one of the founders, possesses, as far as I can find, only one letter; there are none in the University of Pennsylvania, in which he was a professor.

It is needless to reiterate the greatness of Rush. We all know that he was one of the foremost men of his time, a signer of the Declaration of Independence, and the founder of scientific medicine in America.

The following letters from Rush were written to a former student of his, and it was very interesting to me to find the identical letters, to which these are answers, still preserved among the Rush archives in the Philadelphia Library:

PHILADELPHIA, August 24th, 1811.

DEAR SIR: Ancient history informs us that a certain great conqueror, after having planned schemes for subduing several of his neighboring nations, was asked what he intended to do afterward. "Sit down," said he, "and enjoy life." Why can't you do that now? said his friend. You say you are a partner in a business which brings in between 7 & 8000 dollars a year. What can you expect or wish for beyond that income after all the supposed spoils in knowledge which the battles and hospitals of Spain & Portugal might afford you? Sit down *now*, my friend. Enjoy the establishment God has given you and be thankful and happy.

Were your situation less agreeable, and your business less respectable, I would advise you against your contemplated enterprise. The practice of Surgery in the British hospitals I believe is altogether empirical. Much as you would see there, you would probably learn but little. Besides you would be considered by the British Surgeons as an interloper, and probably be treated by them with neglect or contempt, for it is now a part of the British national character to hate an American. Your notes of Dr. Physick's lectures probably contain more knowledge than you would acquire even under the most favourable circumstances in which you could visit the present theatre of war, in the course of two or three years.

All your communications upon medical subjects afford me pleasure. Adieu!

Health, respect & friendship
from, Dear Sir, yours truly,
BENJ'N RUSH.

DR. STUART.

PHILADELPHIA, May 24th, 1810.

DEAR SIR: Since my settlement in Philad'a I have known a great number of Cancer-doctors who have for a while succeeded in curing cancerous sores, but who have uniformly depreciated in character & fortune from their numerous failures or from a return of the sores which were said to have been cured by them. I have observed further that most of those Cancer-doctors pretend to have obtained their remedies from the Indians of our Country, and that they consist wholly of vegetables. The improbability of this being the case appears, from Cancers being unknown among the Indians, and from so small a number of vegetables retaining a corrosive or strongly irritating power when they are dry. I suspect arsenic to be the basis of all those Cancer powders which do not destroy sound as well as morbid flesh. It was the active medicine in the late Dr. Martin's powder, although he pretended it was obtained from a root which grew only in the neighborhood of Pittsburg.

Should you *succeed* in the cure of cancers by the remedy you have mentioned, you would derive but a small profit from your labors, for a majority of the persons afflicted with them are poor people. Should you *fail* in all, or most cases, you would lose the fair & respectable character you have gained by your extensive education and honourable graduation in medicine.

With best wishes for your health and prosperity, I am, Dear Sir,

Yours very respectfully,
BENJ'N RUSH.

DR. STUART.

[ADDRESS] DR. JOSEPHUS B. STUART,
Physician,
Albany,
State of New York.

DEAR SIR: The fact you mention in your letter relative to the effect of stopping the ears with a watch in your mouth, is an interesting one, but it does not call in question the opinion taught in our University. The communication of sound is probably through the medium of the *solid* matters upon which the watch rests, and the seat of hearing. In this way, you know, not only sounds but words have been conveyed to the ear thro' the medium not only of the bones of the head, but the upper and lower extremities in persons who have been deprived of their hearing.

I have salivated your friend Mr. Winans, & thereby I hope put him into a situation to be benefitted by travelling during the summer.

From, Dear Sir,
Yours very respectfully,
BENJ'N RUSH.

PHILADELPHIA, July 4th, 1809.

P. S.: My best wishes & comp'ts to your preceptor.

PHILADELPHIA, June 22d, 1809.

DEAR SIR: An unusual hurry of business has prevented my answering your interesting and sensible letter on an earlier day.

Your treatment of Dr. Willard's case was judicious. The remains of his disease will, I hope, yield to moderately depleting, and tonic remedies according to the *state* of his *pulse*. Plasters of shoemakers' wax to the feet often do great service in diseases of the head. Garlic is a powerful medicine in vertigo *after* the reduction of the pulse. Coffee should not be tasted by him. An issue in his arm may be useful.

The case of Hydrocephalus described in your letter is a curious one. I fear medicine can do nothing for it.

I thank you for the fact respecting the extension of the sense of touch.

I am much gratified in finding that you comprehend my principles, and that you have dared to adopt them in your practice. An edition of Dr. Sydenham with notes will be sent to the press in a few days by,

Dear Sir,

Your sincere friend,

BENJ'N RUSH.

P. S.: Dr. Woodhouse died of Apoplexy. It came on with Hemiplegia. He was ill but five days. A successor to him will be appointed on the 3d of July. The candidates are Dr. Seybert, Dr. Cox, and Mr. Robert Hare.

[ADDRESS] DR. JOSEPHUS BRADNER STUART,
Physician,
Albany,
State of New York.

On referring to the original letters of Dr. Stuart, I find that the case mentioned in the preceding letter was one of cerebral embolism. The most active measures were employed, and it will be interesting, I am sure, to relate the plan of treatment adopted during the first week. Laudanum and ether were given internally; the areas of numbness were rubbed with tincture of cantharides; a blister was applied to the back of the neck; the feet were bathed and sinapisms were applied to them; half an ounce of alkaline julep was administered frequently by the mouth; a blister was applied to the temple for numbness and another to the cheek. After the feet had been blistered by the sinapisms the patient was bled to the extent of six ounces; after this he was given 100 grains of rhubarb and 60 grains of sal tartar. A little brandy and a little porter were also administered, but the record says that they both disagreed. Despite all this the patient is reported to have passed a tolerable night; "took in the course of it 60 grains of calomel." Mercurial ointment was also rubbed in his thighs and under his arms. Brandy and laudanum were again administered.

Static electricity was employed and sparks were drawn from the numb parts; "bled eight ounces;" 35 drops of laudanum administered; niter, aloes, and calomel were added to the long list. Poor Dr. Willard! No wonder he proved a rebellious patient. It seems almost incredible that within a single week so much should have been administered, and that he bore it all as well as he did.

Dr. Stuart[1] was a famous surgeon in Albany and enjoyed a practice of the highest order. The case of hydrocephalus, in reference to which Dr. Rush gives an unfavorable opinion, had been operated upon in those days. It appears that the head measured 39 inches in the eye and ear line, and that Dr. Cussam, of New York, "made an incision down to the brain," without result.

Referring to Dr. Rush's strong advocacy of bleeding and purging, measures which he adopted, and in defence of which he fought fearlessly amid the most bitter opposition, Dr. Stuart says: "I am rallied by the physicians of this city for supporting the principles which you teach in your lectures." Rush's independence in thought, word, and deed, the discovery of principles in his practice, and his defence of them, were truly heroic, and he lived to see them adopted by hundreds of students who flocked to him for instruction; for in days of opposition he had written:

"I had resolved to stick to my principles, my practice, and my patients to the last extremity."

[1] A member of Dr. Stuart's family presented the letters to Dr. Hinsdale.

CORRESPONDENCE.

CASTRATION AS A SUBSTITUTE FOR CAPITAL PUNISHMENT.

To the Editor of THE MEDICAL NEWS,

SIR: At the last regular meeting of the New York Society of Medical Jurisprudence, held at the Academy of Medicine on Monday evening, March 14th, General William A. Hammond, M.D., of Washington, read a paper entitled, "A New Substitute for Capital Punishment, and Means for Preventing the Propagation of Criminals" (*vide* THE MEDICAL NEWS, April 2, 1892, page 390).

Castration is not a *new substitute*, because it has been advocated since the year 1731 (*vide Medical Times and Gazette*, May 25, 1872). Dr. G. F. French, June 11, 1878, read before the Maine Medical Association a paper, entitled, "The Eradication of Syphilis and Crime by the Extirpation, in that Class, of the Procreative Power."

Dr. Orpheus Evarts read before the Cincinnati Academy of Medicine, February 27, 1888, a concise, complete paper entitled "Asexualization as a Penalty for Crime."

Castration is now a live practical topic in large cities. Social science is at present a "fad." Poverty must be abolished. Large families are the cause. What's the remedy? Castrate the husband or the wife. Let us have the ideal Malthusian marriage. Then war, pestilence, and famine will not be needed to remove the overplus of population. Among married American people one child is the rule. Abortion has hitherto been the remedy. Let us give castration a trial. Let us be progressive. Onanism, sodomy, fornication, polygamy, polyandry, abortion, have had their day. The time is now ripe for something new—for castration.

H. A. SHELLEY, M.D.

319 E. 120TH STREET, NEW YORK CITY.

THE PRESCRIPTION OF PROPRIETARY PREPARATIONS.

To the Editor of THE MEDICAL NEWS,

SIR: I wish to emphasize the appeal made to the Editor of THE MEDICAL NEWS in the last paragraph of the letter of Dr. Walker (THE MEDICAL NEWS, April 9th), that we expose worthless nostrums, so many of which are being daily prescribed by so many physicians. It is a growing shame to the medical profession that this habit of prescribing lactopeptin and almost all of the proprietary preparations that are now flooding the country is on the increase, and to an alarming extent.

We know that the bulk of the people of the world are constantly looking for something new, and that there is a great temptation to gratify that inordinate thirst, and that this is done and will continue to be done *ad infinitum;* but let it be done by those that are least responsible and whom the least dishonor can follow. But, for the sake of our high and worthy calling, let not such a disgrace be chargeable to the medical profession.

W. H. BARR, M.D.

AGRICULTURAL COLLEGE, MISS.

THE ACTION OF THE SERRATUS MAGNUS IN FRACTURED CLAVICLE.

To the Editor of THE MEDICAL NEWS,

SIR: When I wrote my article on "Fractured Clavicle," published in your issue of April 9th, I believed that I was original in calling attention to the importance of the action of the serratus magnus in producing and maintaining the displacement of the fragments. Since then, I find that Prof. Gordon had written to the same effect in 1859 (*Dublin Quarterly*), and that without knowing Prof. Gordon's views, Dr. John H. Packard, of Philadelphia, had advanced the same idea in his "Notes on Fractures of the Upper Extremity," in the *New York Medical Journal* for November, 1866, and also in Ashhurst's *Cyclopedia of Surgery* (vol. iv, p. 101). Yet neither Hamilton nor Stimson speak of this, which I believe to be of greater importance than any of the other factors usually mentioned.

Yours truly, EDWARD S. STEVENS.

CINCINNATI, OHIO.

REVIEWS.

THE MÜTTER LECTURES ON SURGICAL PATHOLOGY. (Delivered before the College of Physicians of Philadelphia, 1890–91.) By ROSWELL PARK, A.M., M.D., Professor of Surgery, Medical Department University of Buffalo; Surgeon to the Buffalo General Hospital; Fellow of the German Congress of Surgeons, etc. Reprinted from the *Annals of Surgery*, vols. xiii, xiv, and xv.

THE writer had the opportunity of hearing the lectures of Professor Park, and was at the time struck by the patient and extensive research and noteworthy erudition which they embodied—a ransacking, if we may be pardoned the term, of the literature and researches of modern times, with condensation of the work of the older pathologists. This impression is now deepened by a more careful reading. It is impossible in a review to consider all the subjects with which the volume deals; there are, however, some of sufficient rareness to be worthy of mention here. The study of pus, and of infective processes, with the study of the varying forms of infection up to date, is replete with useful information, as is also the consideration of thrombi. Dr. Park considers clots formed in the circulation—that is, in the blood in transit—as thrombi, a statement undoubtedly open to criticism.

While considering the pyogenic organisms, the author divides them into the obligate and facultative, a division that may have some value. Pus is differentiated into pus, pyoid or puruloid, and archepyon or "originally pus." While there may be some reason for so considering a product of cell-activity combined with processes of degeneration, it is not to us entirely apparent. It may be feared that this proposed method of nomenclature will add to the existing confusion of names, and that really nothing in the matter of actual knowledge is thereby gained. It would, perhaps, be as proper to call urine something else than urine because it contained albumin at one time, or sugar at another, or peptones at another. Microscopically, there are seemingly identical forms of pus, in which the cause may be something else than organisms, certainly differing forms of organisms. We believe that pus may be produced by any cause that has the power of exciting inflammation and at the same time producing degenerative processes in the inflammatory products. This is suggested by Professor Park in the case of some of the alkaloids, and why not in other chemical products? For this reason, if for no other, it does not seem wise to confuse our knowledge of suppuration by attempting to modify the nomenclature of descriptive terms.

For the present, at least, it is highly advisable that we should retain the simplest possible terms for designating the products of the various inflammatory processes, as the comprehension by the profession at large of modern processes in pathology has been vastly retarded, or rendered almost impossible, by the confusion of names of great length, born from the fertile subjects of bacteriology and infective processes.

Lecture IV contains a very fair and scientific classification of the "Results of the Absorption of Products of Wound-infection." In this there are suggested: 1. Surgical fever. 2. Intestinal toxemia. 3. Sapremia. 4. Septicemia. 5. Pyemia. These terms are all sufficiently well known to need no further exposition except that Professor Park has cleared up some of the cloudiest points and clearly and concisely defined each of the conditions named. It seems that under the second condition, intestinal toxemia, there might be also considered similar toxemias occurring in the genito-urinary tract. Thus we all well know there is a well-defined and well-marked course of symptoms that may go with or follow decomposition or retention of catarrhal inflammatory products in the genito-urinary tract. If Professor Park could suggest a term that would cover all such forms of sepsis due to disturbances in the equilibrium of absorption and excretion, he would very much simplify the teaching upon this subject.

The technique for the examination of antiseptics and relative antiseptic values is most excellent. The results of the examination of pyoktanin are presented in such a manner as to be an example of the best methods. Its antiseptic value has, as pointed out by Professor Park, practically been demonstated to be *nil*. The lectures upon Tetany, Actinomycosis, Tuberculosis, and the various infective processes are quite full and up to date. There is a natural tendency in taking up a book for us to make suggestions of what should have been or what might have been added to advantage, but in bacteriology, which forms an important feature in this course of lectures, one cannot fail to note the absence of any illustrations. It is to be hoped that when these lectures have reached a second edition illustrations will be inserted, for thereby the value of the work to the student, to the laboratory worker, and to the teaching surgeon, to whom it must be of the greatest value, will be greatly enhanced.

DISEASES OF THE BLADDER AND PROSTATE. By HAL C. WYMAN, M.Sc., M.D., Professor of Surgery in the Michigan College of Medicine and Surgery, Detroit, etc. Detroit, Mich.: George S. Davis, 1891.

THIS work reflects no credit upon author or publisher. It is likely to do less good than harm. The book is an affront to the profession to which it is offered. No

excuse will mitigate its errors and crudities. We reproduce portions of the book selected at random. The muscular coat of the bladder is described as "made of non-striated muscle-fibers running in all directions around its cavity." In one sentence we find "epididimitis" and "epididymus." Elsewhere micturition is spoken of as "phenomena." It is directed that "the patient should be laid upon a table for examination." For emphasis, perhaps, it is said that "both hands should be used in a bimanual examination." We are told that "the curves possessed by catheters and sounds are adapted to the curve in the male urethra, where it enters and passes through the perineum." Calculi or foreign bodies in the bladder are to "be recognized by their mobility and a peculiar tickling and clicking sound." Examination of the bladder, it is said, among other things, should be "oral" and "aural." "To make" an operation is spoken of. "Whiskey before the anesthetic is administered in quantities sufficient to produce a moderate degree of intoxication lessens the dangers from shock" is, to say the least, an equivocal recommendation. In the report of a case of gunshot injury of the bladder, it is said that the "wounds were closed with interrupted sutures after the Lambert method." The "symphisis" pubis, and "the frog blooded condition of the human system" are mentioned. "A 5 per cent. solution of carbolic acid" is recommended as "a better and safer" local anesthetic than cocaine "to numb the urethra." Among the "sources of inflammation" of the bladder one is said to be "microörganic."

Die Krankheiten der Athem-Organe. Mit specieller Rücksicht auf Japan bearbeitet. Von Dr. E. Baelz, Professor der klinischen Medicin an der Kaiserl. Universität zu Tokio. Mit einem Titelbild in Farbendruck und zahlreichen Holzschnitten. Pp. x, 812. Tokio, 1890.

Diseases of the Respiratory Organs. With Special Reference to Japan. By Dr. E. Baelz.

The three parts that make up this volume evidently represent but one section of a complete handbook of special pathology and treatment, with particular reference to Japan. The necessity for such a work, the first of its kind, lies in the fact that disease in Japan does not present precisely the same features as disease in Europe or America, and that diseases that exist in the one part of the world are wanting in the other. Dr. Baelz is a German, who for fifteen years has been a teacher of clinical medicine in the Royal University at Tokio. In the arrangement of the subject-matter he has adopted an innovation that commends itself for its usefulness. Each main division is introduced by a presentation of the clinical anatomy and physiology of the various parts; then follows a consideration of the general diagnosis and of the general treatment; and finally the individual affections are taken up in the usual manner. Especial attention has been paid to the climatology of Japan. A number of comparative annotations are of interest. It is stated that, except in certain localities in which the disease is endemic, acquired and hereditary syphilis is less common in Japan than in many European countries. While it is admitted that non-infectious membranous laryngitis may arise, as from the inhalation or application of irritants, a distinction between croup and diphtheria is not made. Post-diphtheritic palsy is said to be less common in Japan than in Europe. Among the modes of treatment intubation is considered. Investigations demonstrate that the lungs of the Japanese have a greater vital capacity than those of Europeans. It is thought that the difference may be due to differences in diet, as carbohydrates or albuminoids predominate. In connection with its relation to deformities of the chest, it is said that rhachitis is practically unknown in Japan. In physical examination, palpatory percussion or percutory palpation is recommended for the determination of fine differences in resonance. A gentle blow is struck upon the applied finger of one hand with two or three fingers of the other hand flexed at the second phalangeal joint, the fingers being permitted to remain in contact for a few seconds. It is best to proceed from more to less resonant areas. Dr. Baelz is unqualified in his condemnation of the indiscriminate sending of patients to climatic resorts, as calculated to do as much harm as good. A form of hemoptysis dependent upon the presence in the lungs of the ova of a nematode worm, the *distoma pulmonale*, is stated to be of frequent occurrence in Japan. The condition was first described by Baelz in 1878. In two cases of hemoptysis it is recorded that filaria sanguinis hominis were found. Pneumonia seems to be relatively uncommon, though less so now than formerly. Pleurisy, on the contrary, is more common than in Europe. How well the literature has been covered is evidenced by the fact that the diagrammatic representation of the generation of râles in DaCosta's *Diagnosis* has been reproduced and properly credited.

Dr. Baelz has succeeded in preparing a work that will not only prove most valuable to Japanese students and practitioners, but that can also be read with advantage by medical men in all countries who desire to be informed in the various phases of medical knowledge. The arrangement of the subject-matter is most heartily to be indorsed and commends itself for more general adoption.

Massage and the Original Swedish Movements: Their Application to Various Diseases of the Body. (Lectures before the Training Schools for Nurses connected with the Hospital of the University of Pennsylvania, German Hospital, Woman's Hospital, Philadelphia Lying-in Charity Hospital, and the Kensington Hospital for Women, of Philadelphia.) By Kurre W. Ostrom, from the Royal University of Upsala, Sweden, Instructor in Massage and Swedish Movements in the Philadelphia Polyclinic, etc. Second edition, enlarged. With eighty-seven illustrations. Philadelphia: P. Blakiston & Co., 1891.

This little book contains a brief description of the so-called Swedish movements, and of the various manipulations employed in the practice of massage, together with the indications and contra-indications for therapeutic application. The work will prove especially useful to those pursuing courses of instruction in the subjects treated of. The text is generously illustrated. We notice that in one place massage of the stomach is spoken of as "massage of the ventricle."

THE MEDITERRANEAN SHORES OF AMERICA; OR, THE CLIMATIC, PHYSICAL, AND METEOROLOGICAL CONDITIONS OF SOUTHERN CALIFORNIA. By P. C. REMONDINO, M.D. Illustrated with forty-five engravings and two double-page maps. Pp. 160. Philadelphia: The F. A. Davis Co., 1892.

THE author has prepared this book as a short guide or abridged handbook for persons seeking information of a practical character respecting the climates of Southern California. He shows that this region has fully as varied a climatology as that of the North of Italy, having six distinct classes of climate, each of them having an individual therapeutic value and application. Physicians will find the work helpful when seeking information relative to a suitable climatology for their patients on the so-called "Mediterranean Shores of America."

HUMAN MONSTROSITIES. By BARTON COOKE HIRST, M.D., Professor of Obstetrics in the University of Pennsylvania, and GEORGE A. PIERSOL, M.D., Professor of Histology and Embryology in the University of Pennsylvania. Part II. Illustrated with thirteen photographic reproductions and twenty-five woodcuts. Philadelphia: Lea Brothers & Co., 1892.

THE second volume of this most excellent work contains, in text, descriptions of Celosoma, a form of monstrosity with a more or less extensive body-cleft with eventration, associated with various anomalies of the extremities, of the genito-urinary apparatus, of the intestinal tract, and even of the whole trunk. Six varieties are described, viz.: Aspalasoma (1 plate), Agenosoma, Cyllosoma, Schistosoma (1 plate), Pleurosoma, and Celosoma. Exencephalus (2 plates), Pseudencephalus (5 plates), and Anencephalus (4 plates) are also described, the first class being divided into subspecies—Iniencephalus, Exencephalus, Notencephalus, Proencephalus, Podencephalus, and Hyperencephalus.

INFLUENZA: ITS HISTORY, ETIOLOGY, PATHOLOGY, DIAGNOSIS, COMPLICATIONS, AND TREATMENT. By CHARLES H. MERZ, A.M., M.D. Pp. 96. Sandusky, O.: L. J. Beecher & Co., 1892.

IT is stated that "This little treatise has been written for the purpose of bringing together the latest and best ideas concerning influenza." The subject is certainly an important one and worthy of most careful study. The brochure before us considers in a general way the various features of influenza, but in a manner entirely inadequate to the magnitude of the task.

THE MICROSCOPE AND HISTOLOGY. For the Use of Laboratory Students in the Anatomical Department of Cornell University. By SIMON HENRY GAGE, Associate Professor of Physiology. Part I.: The Microscope and Microscopical Methods. Third edition, entirely rewritten. Pp. 96. Illustrated. Ithaca, N. Y.: Andrus & Church, 1891.

As indicated, this book has been written for laboratory students. It is thoroughly practical in scope and will prove a valuable adjunct in teaching the principles that govern the employment of the microscope, as well as in demonstrating the application of these principles. There is but one way of acquiring a knowledge of the working as well as skill in the use of the microscope, and that is by persevering application. The acquisition of such knowledge and skill may be rendered easy by intelligent direction. It is for this that the book under review commends itself. It is essentially a students' book, from which the most good is to be derived by performing the various manipulations that it directs. It admirably fulfils the objects for which it was written.

SYPHILIS IN ANCIENT AND PREHISTORIC TIMES. By F. BURET, M.D. Translated from the French, with Notes, by A. H. OHMANN-DUMESNIL, M.D., of St. Louis. In three volumes. Vol. I. Philadelphia: F. A. Davis, 1891.

IN translating Dr. Buret's ransackings of history as regards syphilis, Dr. Ohmann-Dumesnil has done an excellent service for the English reader. The numerous quotations throw lurid gleams of light upon the social conditions of ancient peoples, and certainly give proofs of a widespread existence and ancient origin of the disease.

NEWS ITEMS.

A Monument to the late Samuel David Gross, M.D., LL.D., D.C.L. Oxon., LL.D. Cantab., LL.D. Edin., LL.D. Univ. Penna., etc.—American medicine and surgery has had no abler exponent than Samuel David Gross! There has been no man in our profession more honored by scientific associations and learned institutions, both abroad and at home, than Dr. Gross; none who have been more admired by their fellow-practitioners, or revered by former pupils. A boy of studious habits, ambitious promptings, integrity of purpose, and purity of character, without the prestige of a name, or the influence of family or fortune, he rose, unaided, to the highest position in the profession of his selection. A man of marked personal character, with great acquirements, he made an impress upon American surgery which has served to dignify American medicine. His long and brilliant record of deeds well done has claimed the admiration of the world; and since he has passed away and his life-work gone into history, his friends and admirers have been inspired to erect to his memory such a monument as will commemorate his life and character. To further this most praiseworthy object, the American Surgical Association, at its last session, adopted the following resolution:

"*Resolved*, That the President be empowered to appoint a committee with authority to confer with the friends and admirers of the late Prof. Samuel D. Gross, and with the *profession at large*, for the initiation of a movement on the part of the Association, having for its object the erection of a monument to Dr. Gross in the city of Washington, D. C."

The subjoined committee from the Association has been appointed, with authority to confer with the *profession at large*, and solicit subscriptions.

It is not the purpose of the American Surgical Association to claim the honor of erecting this monument to the memory of one of its most distinguished Fellows; but rather is its intention to *initiate* a movement in

which the entire American profession should feel an equal interest; because Dr. Gross was of no exclusive faction, but a leading member of the whole profession.

Hence it is that each member of the committee is instructed to appoint sub-committees in his own State, irrespective of fellowship in this or any other association, which sub-committees will aid him in the collection of contributions to the general fund.

Any contributions may be sent to Dr. John B. Roberts, 1627 Walnut Street, Philadelphia. He is the Treasurer of the Association, and will receipt for the same, and from time to time acknowledge subscriptions through the columns of the *Journal* of the American Medical Association. In the event of a failure to collect a sum sufficient to complete the monument, the contributions will all be returned to the subscribers.

Estimates have been made of the amount required to erect an imposing statue of bronze, of heroic size, upon a granite pedestal, the whole to be about sixteen feet in height; all to be delivered to the committee in the city of Washington, showing that the cost will not exceed $12,000. It will probably be less.

Some admiring friends of the late Prof. Gross have authorized us, on behalf of the committee, to draw upon them, at sight, for $3500, at any time that the money may be required to make up the estimated amount. This sum will be increased by other friends who feel an interest in the matter, if necessary.

With this amount, *now assured*, it will be necessary for the committee to raise by subscription not more than $8000, or possibly $8500, a very small sum to be drawn from the whole of the United States, when we consider the object for which it is intended.

J. R. Weist, M.D., Chairman.
C. H. Mastin, M.D., Secretary.

Committee.—Drs. Wm. T. Briggs, Tennessee; Levi C. Lane, California; Solon Marks, Wisconsin; L. S. Pilcher, New York; A. Vander Veer, New York; James McCann, Pennsylvania; D. Hayes Agnew, Pennsylvania; J. Ewing Mears, Pennsylvania; S. H. Weeks, Maine; Hunter McGuire, Virginia; L. McLane Tiffany, Maryland; N. P. Dandridge, Ohio; H. H. Mudd, Missouri; J. Collins Warren, Massachusetts; B. A. Watson, New Jersey; D. W. Yandell, Kentucky; N. Senn, Illinois; Charles B. Nancrede, Michigan; W. H. Carmalt, Connecticut.

The Association of American Physicians will hold its next annual meeting in the Medical Museum and Library, Washington, D. C., May 24, 25, and 26, 1892.

The subject selected for discussion is Dysentery. Dr. Wm. T. Councilman, as Referee, will consider the Etiology and Pathology, and Dr. A. Brayton Ball, as Co-referee, the Symptomatology, Complications and Treatment.

The following members will present papers:

Dr. Henry M. Lyman, "The President's Address."

Dr. Charles Carey, "The Production of Tubular Breathing in Consolidation and Other Conditions of the Lungs."

Dr. Samuel C. Chew, (Title to be announced).

Dr. William C. Dabney, "A Contribution to the Study of Hepatic Abscess."

Dr. I. N. Danforth, "Tube-casts and their Diagnostic Value."

Dr. George M. Garland, "The Treatment of Follicular Tonsillitis."

Dr. Heneage Gibbes, "The Morbid Anatomy of Leprosy."

Dr. Hobart A. Hare, "A Collective Investigation in regard to the Value of Quinine in Malarial Hematuria or Malarial Hemoglobinuria."

Dr. Jacobi, (Title to be announced).

Dr. W. W. Johnston, "Treatment of Acute Dysentery by Antiseptic Colon and Rectal Irrigation."

Dr. Thomas S. Latimer, "Alcoholism."

Dr. Morris J. Lewis, "A Study of the Seasonal Relations of Chorea and Rheumatism for a Period of Fifteen Years."

Dr. Morris Longstreth, (Title to be announced).

Dr. Francis T. Miles, "A Case presenting the Symptoms of Landry's Paralysis, with Recovery."

Dr. William Pepper, "Report of a Case of Glanders, with the Results of Bacteriological Study."

Dr. T. Mitchell Prudden, (Title to be announced).

Dr. George M. Sternberg, "Practical Results of Bacteriological Researches."

Dr. Charles G. Stockton, "Misconceptions and Misnomers Revealed by Modern Gastric Research."

Dr. William H. Thompson, "The Significance of Intermission in Functional Nervous Diseases."

Dr. Victor C. Vaughan, "Certain Toxicogenic Germs found in Drinking-water."

Dr. B. F. Westbrook, "Studies in Hypnotism."

Dr. James C. Wilson, "Pulsating Pleural Effusions."

Dr. George Wilkins, "The Cold-water Treatment of Typhoid Fever."

American Academy of Medicine. *Preliminary Program.*—The following topics are promised for discussion at the Seventeenth Annual Meeting of the American Academy of Medicine, at the Cadillac Hotel, Detroit, Mich., on Saturday, June 4, and Monday, June 6, 1892:

1. "Essentials and Non-essentials in Medical Education;" the Address of the retiring President, Dr. P. S. Conner, of Cincinnati. 2. "The Value of the General Preparatory Training afforded by the College, as compared with the Special Preparatory Work suggested by the Medical School in the Preliminary Education of the Physician;" a paper by Dr. T. F. Moses, of Urbana, Ohio. 3. "Does a Classical Course Enable a Student to Shorten the Period of Professional Study?" a paper by Dr. V. C. Vaughan, of Ann Arbor, Mich. 4. "The Value of a College Degree as an Evidence of Fitness for the Study of Medicine;" a paper by Dr. L. H. Mettler, of Chicago. 5. "The Value of Academical Training Preparatory to the Study of Medicine;" a symposium, by Drs. H. B. Allyn, of Philadelphia, W. D. Bidwell, of Washington, and Elbert Wing, of Chicago. 6. "The Newer Medical Education in the United States;" a symposium, by Drs. W. J. Herdman, of Ann Arbor, Charles Jewett, of Brooklyn, and Elbert Wing, of Chicago. 7. A paper on "Some Phases of the State Supervision of the Practice of Medicine," by Perry H. Millard, of St. Paul. Some other papers are partially promised, and the usual reports may be expected from the committees. Members of the profession are cordially invited to be present at the sessions of the Academy.

The Suppression of Empiricism.—The following ordinance has been passed in Bowling Green, Lexington, Paducah, Harrodsburg, Lebanon, Elizabethtown, Stanford, Franklin, Glasgow, and several other cities, and is pending and will be passed in nearly every other city and town in the State of Kentucky:

SEC. 1. That it shall be unlawful for any travelling or itinerant doctor to practise medicine in any of its branches within the limits of this city. To open an office for such purpose, or to announce to the public in any other way an intention to practise medicine shall be an offence within the meaning of this ordinance. *Provided*, that nothing in this ordinance shall be so construed as to prohibit any reputable physician or surgeon from any other place being called to see a particular case or family, or to do a particular surgical operation in said city.

SEC. 2. Any person convicted of a violation of the provisions of Section 1, of this ordinance, shall be fined the sum of not less than $50 nor more than $100 for each day so engaged in the practice of medicine.

SEC. 3. This ordinance shall be in effect from and after its passage, and all ordinances or parts of ordinances in conflict with the provisions of this ordinance are hereby repealed.

New York Presbyterian Hospital.—The following staff of officers was appointed April 12th:

Special Consultants: Gynecologist, Dr. T. G. Thomas; Neurologist, Dr. M. Allen Starr; Laryngologist, Dr. F. H. Bosworth; Ophthalmologist, Dr. C. S. Bull; Otologist, Dr. A. H. Buck; Orthopedist, Dr. N. M. Shaffer; Dermatologist, Dr. George T. Jackson; Surgeon, Dr. Fred. E. Lange.

Visiting Physicians: Dr. F. P. Kinnicutt, Dr. Wm. P. Northrup, and Dr. W. B. James.

House Staff—to go on duty July 1, 1892:

Medical: Second Assistant Physician, Dr. F. H. McMasters; Third Assistant Physician, Dr. David Bovaird, Jr.

Surgical: Second Assistant Surgeon, Dr. Ernest Schultze; Third Assistant Surgeon, Dr. Ed. H. Pershing.

No. 2—to go on duty January 1, 1893:

Third Assistant Surgeon, Dr. R. Forbes Hawkes; Third Assistant Physician, Dr. J. P. Thornly.

A Bureau of Service and Information for Physicians at the Columbian Exposition.—Chas. Truax, Greene & Co., an enterprising physicians' supplies house of Chicago, announces that during the Columbian Exposition it will establish and maintain a bureau of service and information for medical men. Provision will be made for registration, the reception of mail-matter and telegrams, the transaction of banking, and information will be furnished as to hotels and boarding-houses and other matters of interest and importance to visitors. A cloak-room, a reading-room, a reception-room, and other conveniences will also be provided.

Alvarenga Prize—The Hufeland Society of Berlin offers a prize of eight hundred marks ($200) for the best essay upon "Basedow's Disease: Its History, its Pathology and Pathologic Anatomy, its Etiology, its Treatment." Essays in competition should be in the hands of Professor Liebreich, of Berlin, before April 1, 1893.

A Correction.—THE MEDICAL NEWS has allowed itself to be misled into an inaccurate statement, for which it owes an apology to its readers, to itself, and to a good cause that it might have damaged by a bad argument.

"As a matter of fact, a reliable preparation of theobromine sodio-salicylate" can *not* be obtained for less than $1.75 per ounce, av.; the price of diuretin (Knoll) is $2.50 per ounce, av. There is a difference, but not so great as we erroneously stated.

The American Electro-therapeutic Association will hold its second annual meeting in the New York Academy of Medicine, October 4, 5, and 6, 1892.

BOOKS AND PAMPHLETS RECEIVED.

Psycho-therapeutics; or, Treatment by Hypnotism and Suggestion. By C. Lloyd Tuckey, M.D. Third Edition, Revised and Enlarged. London: Ballière, Tindall & Cox, 1891.

Tobacco, Insanity, and Nervousness. By L. Bremer, M.D. Pamphlet, 1892.

Aphasia due to Sub-dural Hemorrhage without External Signs of Injury. By L. Bremer, M.D., and N. B. Corson, M.D. Reprint, 1892.

The New Lake in the Desert. By William A. Edwards, M.D. Reprint, 1892.

Concerning American Indian Womanhood. An Ethnological Study. By William Thornton Parker, M.D. Reprint, 1892.

Lectures on Tumors. By John B. Hamilton, M.D., LL.D. For the Use of Students. Second Edition. Detroit, Mich.: George S. Davis, 1892.

Accidents from the Electric Current. By Philip Coombs Knapp, A.M., M.D. Reprint, 1892.

Two Cases of Trephining for Traumatic Epilepsy. By Philip Coombs Knapp, A.M., M.D., and Abner Post, M.D. Reprint, 1892.

A Case of Tumor of the Cerebellum, etc. By Philip Coombs Knapp, A.M., M.D. Reprint, 1892.

Astasia-abasia, with Report of a Case. By Philip Coombs Knapp, A.M., M.D. Reprint, 1892.

Mme. Lachapelle, Midwife. By Hunter Robb, M D. Reprint, 1892.

ORIGINAL ARTICLES.

ECLAMPSIA.

BY W. A. DEWOLF SMITH, M.D.,
OF NEW WESTMINSTER, B. C.

ON December 27, 1890, I was called to see Mrs. M., who was supposed to be in labor. On arriving at the house I found that the patient, who was a young primipara, had had sharp pains for some hours before my visit. As they appeared to be merely false pains, I prescribed suitable remedies and left her. I heard nothing more of the case until January 15, 1891, when I was again summoned to see her on the supposition that labor had begun. At this visit I found the patient suffering from the same pains as before, but in addition there was great edema of the feet, legs, and vulva, so that she was unable to stand, walk, or to sit in an ordinary position. I prescribed calomel and jalap, and punctured the vulva in several places with a fine needle. On my visit next morning I found that the pains had ceased and the swelling of the vulva had much decreased. The feet and legs were about as large as on my previous visit, the ankles measuring 10½ inches in circumference. On that evening, at about 6 o'clock, I was again hurriedly sent for, the messenger stating that the woman was in a fit. When I arrived at the house the convulsion had passed off, and had left the woman in a state of semi-unconsciousness. Shortly after my arrival she had another convulsion, at the beginning of which I injected ¼ grain of morphine hypodermatically; but this not acting rapidly enough, I began the administration of chloroform by inhalation, which at once cut the convulsion short, the patient again subsiding into the semi-unconscious state.

I now secured a consultation with Drs. Walker and Fagan, and there being a large (about 30) per cent. of albumin in the urine, and the convulsions recurring at intervals of about twenty minutes, necessitating the almost constant use of chloroform to keep them under control, we decided to empty the uterus at once.

The convulsions began in the hands, usually the left hand, then extended to the right, and finally spread to the body and face, the latter being frightfully distorted, the mouth being drawn up on the left side. During a convulsion the breathing was jerky, and at the end of a seizure ceased altogether, so that artificial respiration had to be resorted to after each attack. The frequent employment of enemata of chloral, bromide, and milk with whiskey, quieted the patient somewhat, but she was evidently getting weaker after each attack, so that after putting her completely under chloroform I dilated the os with the fingers, and turned and delivered without difficulty a dead child—a male, and rather small. After delivery there was absolutely no hemorrhage, the uterus contracting firmly and remaining so. No douching was employed. After the birth of the child the woman had no more convulsions, merely becoming a little restless from time to time.

The pulse being weak and flickering, she was ordered small doses of milk and whiskey every hour until the next day, when the milk was increased to two ounces with a teaspoonful of whiskey every hour, and this was afterward changed to three ounces of milk every hour, with a tablespoonful of whiskey every three hours.

From this time the case progressed favorably; the urine, although of a dark color, being passed voluntarily, and the albumin decreasing in amount from day to day. It was not until the third day after delivery that the patient regained her senses, although previously she would answer when spoken to loudly.

She was on the 18th put upon liquor ferri dialysati with infusum digitalis, with the result that in a few days the swelling of the feet and ankles entirely disappeared. On the twelfth day after delivery the albumin disappeared from the urine. It reappeared occasionally for the next five or six days, when it finally disappeared. When the patient was allowed to get up she was put on a mixture containing the citrate of iron, quinine, and strychnine, and has made a good recovery.

The temperature never rose above 99.5°, and on the fourth day after confinement fell to normal, where it afterward remained. The lochia presented no unusual feature; on one occasion there was a little unpleasant smell, but a carbolized douche set it quite right again. For some days there was considerable distention of the abdomen, with tenderness and pain, which, however, yielded to turpentine stupes.

Causes. The causes of puerperal convulsions are by no means certain, and all authors seem to feel the uncertainty of the ground. Churchill(1) says that "they doubtless arise from the sympathy of the brain with the irritation of some different and often distant organ—it may be the uterus, the stomach, or the bowels." He also gives as causes, intemperance in eating or drinking, mental emotions and frights, efforts made during the labor-pains whereby an accumulation of blood takes place in the head, and atmospheric influences. The possibility of the kidneys being in any way implicated as a cause does not seem to have occurred to observers of that time, although a little further on he mentions(2) the fact

that Dr. Levis, of London, had detected the presence of albumin in the urine of such patients, and deems it an important test in doubtful cases.

Playfair ([3]) states that although the urinary origin of eclampsia has been pretty generally accepted, more recent observations have tended to throw doubt on its essential dependence on this as a cause, and he mentions the researches of Braun and Frerichs, who supported the view that the convulsions were due to the retention of urea in the blood (although Frerichs believed it to be decomposed into ammonium carbonate), and those of Hammond ([4]) and Spiegelberg ([5]), who opposed this view.

Later on it was shown that albumin in the urine did not necessarily mean puerperal convulsions, and cases to prove this were collected by Goubeyre, Blot, and Braxton Hicks ([6]). Traube and Rosenstein referred the occurrence of eclampsia to acute cerebral anemia with edema, due to changes occurring in the blood during pregnancy ([7]).

MacDonald ([8]) found anemia of the brain, but no edema.

Dr. A. F. King ([9]) proposes the theory that the eclampsia is due to the pressure of the uterus on the great vessels (aorta and inferior vena cava), which causes both the cerebral and renal troubles.

Dr. A. L. Smith ([10]) has arrived at the conclusion that the cause is uremic, and that the convulsions depend on edema and anemia of the brain.

In a paper read before the Gynecological Society of Chicago, Dr. W. W. Jaggard ([11]) favors the view that the convulsions are caused by cerebral anemia, which in its turn is caused by vasomotor spasm.

Dr. Bayard Holmes ([12]) believes in the bacterial origin of puerperal eclampsia, the bacteria finding an entrance through the intestinal tract.

A new theory of the cause of puerperal eclampsia —or rather, as the author puts it, of a form of eclampsia puerperalis—is that advanced by Mr. W. T. Coleman ([13]), which is that at least one form of the disease is due to the sudden and forcible extension, and consequently stretching, of the cervix uteri —independently of the presence of albumin. He relates three cases—one of which proved fatal—occurring in his own practice, in which convulsions supervened on the sudden distention of the cervix. In at least two of his cases there was no albuminuria after delivery, and no signs indicating it before that event. This must, however, be a very infrequent cause, for in many cases the convulsions occur either before or after any occasion for stretching of the os, and in most cases in which convulsions occurred during delivery no mention is made of the fact that the passage of the head in any way increased the tendency to eclampsia. In this connection the question occurs to one, whether the tremblings so often seen during the first stage of labor, which are entirely beyond the control of the patient, and are not due to any apparent cause, such as fear or cold, may be due to such stretching of the os, and whether in the cases mentioned by Mr. Coleman, the eclampsia was but an exaggerated form of these nervous tremblings.

Galabin ([14]) is of the opinion that the cause is uremic, and requires further proof before he can accept the view of Dr. Braun, that bacilli are the immediate cause of the convulsions.

Recent German writers have put forward the idea that "the fetus may play a not unimportant part in the causation of the convulsions, as indicated by the predisposition to convulsions in twin and triplet pregnancies, and by the fatal effect on the child, and by the fact that the death of the child during pregnancy materially lessens the danger to the mother." (Winckel).

Dr. Robert Barnes ([15]) rejects the idea that of necessity there is any disease of the kidneys, or that albuminuria is the cause, but considers that the immediate cause of the convulsion is some poison—as yet not definitely known—circulating in the blood. This condition is not the sole cause, but a certain proportion of the result is due to the increased nervous and vascular tension, which in its turn is associated with the hypertrophy of the heart normally taking place during pregnancy.

As already stated, Churchill ([16]) observes that "atmospheric influence appears to have some effect in determining the frequency of the disease. Most persons must have remarked how often a number of cases occur about the same time, as though depending on some general cause." What relation this remark, made in 1848, may have to the proposition enunciated by Dr. Bayard Holmes, in 1889 ([17]), *i. e.*, that bacteria are the cause of the disease, is left for others to determine. The weight of opinion seems to be that the eclampsia is caused by some poison circulating in the blood, but the nature of the poison and the relation it bears to the albuminuria is not yet settled.

Symptoms. The symptoms of an approaching attack of eclampsia are in many cases not sufficiently striking to attract any attention to themselves until the disease is actually *en evidence.* In a few cases there have been warnings, such as restlessness, nervousness, headaches, and loss of sight, but they are by no means constant or distinctive, while even albuminuria and edema are not at all to be relied upon as symptoms, for both or either may be present in a case that does not develop convulsions, or convulsions may be present in a case in which there is neither albuminuria or edema.

Pathology. The pathology of the disease is not more definitely settled than is the cause. In some

cases there have apparently been found changes in the kidneys indicative of nephritis, whilst in others these have been wanting altogether. In some cases changes have been observed in the liver by certain German and French observers. Thus Paultauf and Kundrat, in 1888, and Koffer and Kundrat, in 1891 ([18]), report cases in which hemorrhagic hepatitis was found. Papillon and Audain ([19]) also found multiple ecchymoses beneath the capsule of the liver, while microscopically there was fatty degeneration of the liver-cells, with multiple thromboses of the venous radicles, and infiltration with masses of fibrin. Dr. Schmorl, of Leipzig ([20]), in fifteen cases found necrotic foci in the liver, which he divided into hemorrhagic and anemic. The same observer has also found hemorrhages of the brain in most of his cases, and in five of the fifteen there was necrosis of the pancreas and heart. M. Doleris ([21]) found that some specimens of urine from patients dying with eclampsia yielded certain crystals of an indeterminate nature, a solution of which caused death when injected into rats and sparrows. He also found changes in the livers of these patients.

Occurrence. Puerperal eclampsia appears to be slightly more frequent among primiparæ than among those who have borne more than one child. Thus, in fifty-six cases that I have collected, the number of pregnancies is mentioned in forty-seven, and of these, twenty-six, or over 55 per cent., were primiparæ, the remainder having borne from two to nine children. The cases that I have been able to collect do not bear out the theory that eclampsia is more frequent in plural than in single births, for of the fifty-six cases four only are mentioned as cases of twins.

Prognosis. Puerperal eclampsia is an extremely fatal disease, both to mother and child. Of fifty-six mothers, fifteen, or nearly 28 per cent., died, while of thirty-five children regarding which the fact is mentioned, eighteen, or nearly 52 per cent., were dead.

Complications. Besides coma, which is an almost constant accompaniment of the disease, and which is doubtless really a part of it, complications are not frequent. Hemiplegia occurred four times in the fifty-six cases; icterus is mentioned twice; ptosis (of the left eyelid), mania, and purpura, once each. By far the greater number of cases that do recover appear to do so rapidly and completely as soon as the cause of the disease is removed.

Treatment. As regards the treatment of puerperal eclampsia there is no unanimity of opinion. Bleeding, which is one of the oldest remedies, still has its supporters([22]), while others ([23]) do not appear favorable to it. Steele ([24]) and Barnes ([25]) occupy a judicious mean, and intimate that it may or may not be useful, Barnes recommending it in selected cases.

Other remedies that meet with more general acceptance are chloral hydrate and potassium bromide, which have been highly recommended, but in many cases are found to fail.([26]). These remedies are usually combined with purgatives, diaphoretics, and diuretics. Morphine alone, or with chloral or atropine, has been highly recommended, particularly by Alban ([27]) and Teevan ([28]), who regard it as almost a specific. Oxygen has been tried ([29]), and is said to have acted well, but has not come into general use. Pilocarpine and antipyrin have their advocates also, but the use of neither has met with much success. Pilocarpine, particularly, I consider unsafe in these cases. In the case recorded I administered one dose of it, but it caused the secretion of so much saliva that in her semi-comatose condition the woman was nearly choked. Amyl nitrite has been recommended in this disease by observers who believe that the anemia of the brain is caused by vasomotor spasm, and Barnes has seen good results from its use. A few German observers have advocated Cæsarean section in these cases, but without advancing any arguments which seem to me convincing. Thus, Halbertsma ([30]) has collected ten cases of eclampsia treated by Cæsarean section, with two deaths, or 20 per cent., against a mortality of 17 per cent. in twenty cases treated by narcotics and warm baths. It is also recommended by Löhlein ([31]), and Swiecicki ([32]) and Von Herff ([33]) each record a case, the former losing both mother and child, the latter saving both. The operation is advised by Halbertsma in severe cases when some time must elapse before labor can occur; by Löhlein, when dilatation is not sufficiently advanced to permit delivery, when the child lives and is vigorous, while other treatment fails to subdue the convulsions, and respiration and heart-action are threatened. Swiecicki and Von Herff admit it to be called for only when the child lives and the genital canal is entirely undilated. These indications are, in my opinion, satisfactorily met by the course of treatment recommended by the majority of English and American authorities, viz., the administration of chloroform and rapid delivery. For cases in which convulsions occur before delivery, this treatment is usually satisfactory, and in the majority of cases in which convulsions occur after delivery they are mild in character and can be controlled by chloral and bromide administered by the mouth or by enema. Even in cases reported by writers who recommend bleeding, chloral and bromide, or morphine, it is almost invariably recorded that chloroform was given and the uterus emptied as soon as possible. In some cases of convulsions after delivery it has been necessary to resort to chloroform to control the spasms. This line of treatment is not universally recommended, for

Churchill[34] says: "I believe there is no dispute that until labor sets in naturally interference would be injurious, so that in convulsions during gestation we have nothing to do with the uterus, but must confine ourselves to the treatment of the convulsive disease." Playfair is scarcely less emphatic on the subject, for he says[35]: "If, therefore, the os be undilated, and labor have not begun, no active means to induce it should be adopted, although the membranes may be ruptured with advantage, since that procedure tends to no irritation. Forcible dilatation of the os, and especially turning, are strongly contra-indicated." Other authorities—as Ramsbotham, Gooch, and, more recently, Barnes[36]—recommend early emptying of the uterus, and the weight of modern opinion is in favor of this procedure as fulfilling all indications. Certainly, it seems that, as pregnancy appears in some way to be the cause of the eclampsia, the most rational method of treating the disease is by removing its cause, rather than to temporarily subdue the symptoms and leave the cause to continue in action.

GONORRHEA OF THE VESICULÆ SEMINALES (SPERMATO-CYSTITIS).

BY FRED BYRON ROBINSON, B.S., M.D.,
OF CHICAGO, ILL.
PROFESSOR OF GYNECOLOGY IN THE CHICAGO POST-GRADUATE MEDICAL SCHOOL.

FOR several years I have watched the effect of gonorrhea in a number of European countries and in the United States. I have learned some pertinent facts relative to gonorrhea and also to syphilis. One fact is that gonorrhea and syphilis vary much in different great cities. I saw also that occasionally where gonorrhea was the most virulent, there syphilis was the most mild. For example, gonorrhea in Birmingham, England, is almost malignant in its virulence, while syphilis is quite mild. In fact, syphilis is so mild in Birmingham that the surgeons are accustomed to say, when a severe case presents itself to them, that it is not Birmingham syphilis, but that all severe cases of syphilis were acquired in other cities. On the other hand, syphilis is very severe in Edinburgh, while gonorrhea is of a mild type. So that gonorrhea varies in its intensity in various places just as many other diseases are likely to do. Another subject of interest is the effect of gonorrhea of the *vesiculæ seminales*. I have made an investigation on the subject of the semen sacs of some of the lower animals. I did some work on the dog and boar, but especially on the bull. While dissecting the semen sacs of those animals I was impressed with the regularity of the sacs. They had no irregular dilatations, no loculi or sacculated swellings. The vesicles in those animals had a uniform shape, and I never found them bound down by old or recent adhesions. In fact I never once found an inflammation in the semen sacs of the lower animals. I had dissected the semen sacs of man for some time, and the idea of the great difference between the healthy appearance of the semen sacs of animals and those of man came into my mind. I followed this subject for several years as time and occasion presented, especially in instruction in anatomy. I noticed that the majority of male subjects of dissection had some old inflammatory trouble in the seminal vesicles. These unhealthy semen sacs are not regular. Their walls bulge out here and there in a sacculated condition; their loculi are not uniform, and their walls are thinner at some places than others.

The vesicles are bound down by partial or complete adhesions, and it requires a long time to free

the sacs from the mass of inflammatory products. Now, when these old inflammations exist with distinctive prominences, and we find the seminal vesicles in a solid mass, gonorrhea can be traced with pretty fair certainty. Such men have had gonorrhea for years. In 1884 I listened to the teachings of the Germans at Berlin, but heard nothing of gonorrhea of the seminal vesicles. In 1887 I was profoundly impressed with the grand teaching and work of Professor Ultzmann, and also of Professor Dittel. I watched those men perform autopsies, from the glans penis to the top of the bladder, but I did not hear any discussion of the diseases of the vesiculæ seminales. They did not even speak of any old inflammation of the semen sacs as the result of gonorrhea. They continually spoke of *prostatitis*. When patients died and the genito-urinary tract was slit open, the appearance of the walls of the prostate and its size did not always satisfy me that all the pain of which those patients complained during life could be accounted for by that kind of a prostate. Some of those very prostates were even very respectable in appearance. To be sure, they had an immoral history, but that does not always condemn them to prostatitis. I was also sure that the back of those "condemned prostates" looked sufficiently large. I felt convinced that some of the prostatitis was nothing more than inflammation of the seminal vesicles. But when one thinks differently from able men like Professor Ultzmann or Professor Dittel he is apt to say it was an error, and that such men are always right, or at least a different idea will have a poor show of being correct. As a gynecologist I do not lay any particular claim to knowledge of other fields, but in gynecology I have had innumerable opportunities to know full well that gonorrhea is a terrible scourge to the Fallopian tubes of women, but it does not limit itself to the tubes. The coccus of gonorrhea has no respect for the tubes of tender girls or elder matrons, but ruins all alike.

Gonorrhea soon makes a pyosalpinx, which often ends as a hydrosalpinx. Not everyone will believe that a pyosalpinx may finally end as a hydrosalpinx. Now, the vesiculæ seminales and vasa deferentia are the exact analogues of the Fallopian tubes. And, so far, there has been presented no good reason why the gonococcus should jump from the prostate to the testicle without cultivating the very arable lands intermediate. The choice soil of the gonococcus is mucous membrane, and hence the vesiculæ seminales and vasa deferentia cannot escape when the germs go over its nourishing ground. Two years ago I could find no publications on the subject of gonorrhea in the semen sacs, and I began to believe that my idea of gonorrhea in those vesicles was of no value.

About a year ago I made a visit to Birmingham, England, and while there I met two men who had also done some work on the subject. One was Mr. Jordan Lloyd and the other was Mr. Marsh. This renewed my interest in the subject, and I investigated it further with those men. I wrote several short articles on it, but never heard a single comment on it. It was as if they had never been written. Mr. Lloyd told me I was the first man he had met who believed it was a matter of importance. Mr. Marsh had done some good work on the subject, and I examined some patients of his in which we believed the disease was inflammation of the seminal vesicles. One patient whom I examined showed no supra-pubic pain, no tenderness in the perineum. The *prostate was not enlarged* as we examined it per rectum, nor was it painful; but on either side of the rectum, a little higher up, a globular swelling, exquisitively tender and painful when touched, was felt. This swelling was the seminal vesicles and surrounding tissue. His temperature was 100.9°. His bowels were constipated, and when they acted they caused him intense pain. As time went on, the man improved. The seminal vesicles became smaller by absorption, but the sacs remained somewhat enlarged and thickened. This was a typical case of spermato-cystitis. Gonorrhea could be traced in most of the cases with certainty.

Mr. Jordan Lloyd had done extensive work in the subject, and I was much delighted to meet a man pursuing the same thought. In dissecting, I had not preserved my specimens, but Mr. Lloyd had saved his, and showed me dozens he had collected of diseases of the seminal vesicles. In fact, he had dissected scores of bladders and prostates in his investigations of the matter. After my dissections of the seminal vesicles of animals and men in Toledo and Chicago, and examination of clinical cases as they arose, and the work of Mr. Marsh, but especially of Mr. Lloyd, I am thoroughly convinced that the prostate gland is not responsible for all the ills put upon it. I feel quite sure now that when a man gets disturbance at the neck of the bladder it must not always be put down as *prostatitis*, but spermato-cystitis has a share in the disease. Of course, gonorrhea is at the bottom of the inflammation of the seminal vesicles. Now, the Fallopian tubes dilate and suppurate from gonorrhea, or the disease may remain as chronic endo-salpingitis for a long time.

No observing medical man doubts that orchitis follows gonorrhea. Few men will doubt that gonorrhea does not cause suppurating testicle. Now, I claim that gonorrhea causes inflammation and *suppuration* of the seminal vesicles.

Mr. Jordan Lloyd reported to me several typical

cases of inflammation of the seminal vesicles, and they suppurated and he opened the abscesses.

Dr. A. Goldspohn, of Chicago, reported to me that he had a very distinct case in which the seminal vesicles suppurated. Dr. Goldspohn told me that his case of spermato-cystitis was positively and clearly traced to an attack of gonorrhea. Dr. Goldspohn opened the suppurating semen sacs through the perineum and the man recovered. I suggest that abscess of the seminal vesicles should always be opened through the perineum and not the rectum.

No doubt others could report similar cases. But prostatitis has so long been the scapegoat of all disease at the neck of the bladder that it is difficult to change medical opinion.

A post-mortem I performed last week with Dr. Sutherland renewed my interest in this disease. The autopsy was on a man about thirty-five, of good physique. Close to the base of the bladder we noticed some swelling, and on the swelling being dissected out it proved to be two enormously dilated semen sacs. One sac was three inches long, three-quarters of an inch wide, and one-half inch thick. The other seminal vesicle was not quite so large, but nearly so. In this case I wished to be certain whether gonorrhea had caused the trouble, so Dr. J. L. Sutherland, of Grand Island, Neb., kindly undertook a careful examination of the contents. He found the gonococcus. To confirm his diagnosis, Dr. Sutherland took the specimen to Dr. Wesener, a microscopic expert of Chicago, who, without knowing anything of the case, at once pronounced it the gonococcus. Dr. Wesener said it was a specimen of old standing because the gonococcus had broken out of the pus-cell. This, then, is a typical case of spermato-cystitis which went on to suppuration. It was caused by the gonococcus. The semen sacs had not ruptured, nor had they formed many strong adhesions.

I could adduce much more evidence in favor of the distinct existence of spermato-cystitis, but I will conclude by a short, concise summary which will embody the ideas I have obtained during the past three years. When I started I could find no publication on the subject. In fact, I did not know what name to apply to the disease. Also, three years ago I had no idea that gonorrhea was such a terrible scourge to woman and man as it really is. But a study of my cases of gonorrhea was then impressing me with its magnitude, and I should think that gonorrhea caused *nearly all* spermato-cystitides.

We, of course, have *hydro-spermatocysts* and *pyo-spermatocysts*, but these are simply different stages of the same process. A pyo-spermatocyst may end in a hydro-spermatocyst.

CONCLUSIONS.

1. The seminal vesicles are attacked by inflammation that induces obstruction and causes dilatation.
2. The dilated sacs contain fluids or pus.
3. Gonorrhea is the principal cause of the disease.
4. The disease of the semen sacs is exactly analogous to those of the Fallopian tubes, and mainly has the same cause.
5. It follows urethritis and generally exists with epididymitis.
6. It rarely suppurates. But epididymitis also rarely suppurates.
7. It is nearly always diagnosticated as prostatitis.
8. If suppuration occurs, the abscess should be opened, not through the rectum but through the perineum.
9. The vesiculæ seminales may be swollen quite large and yet few adhesions exist around them, as I have seen in autopsies. But this exactly resembles hydrosalpinx. Adhesions vary much in both diseases.
10. A hydro-spermatocyst or a pyo-spermatocyst may recover without medical or surgical interference, just as will a hydrosalpinx or pyosalpinx.
11. To diagnosticate disease of the vesiculæ seminales an examination should be made by the rectum.
12. It is in the semen sacs that we likely have a favorable place for persistent remains of gonorrhea. Post-nuptial sexual excesses reëxcite old gonorrhea into virulent activity.
13. The dilatation of the semen sacs and their inability to retract, or loss of sphincter power, may account for some cases of spermatorrhea.

ORIGINAL ADDRESSES.

THE ETIOLOGY, DIAGNOSIS, AND TREATMENT OF THE PREVALENT EPIDEMIC OF QUACKERY.

An Address delivered by Invitation of the Faculty of the Medical Department of the Buffalo University, before the Graduating Class, May 3, 1892.

BY GEORGE M. GOULD, M.D.,
OF PHILADELPHIA.

You have all heard of the doctor who would never eat roast duck because this impolite animal had always been so personally insulting to him in its remarks. Doubtless you may wonder if I am not also a bit impertinent in choosing the subject of quackery as a theme of talk before physicians regularly educated and presumably despising irregularity and sectarian medicine with just indignation. I assure you it is not because I suspect you of infidelity—at least of a very pronounced type. I simply wish to give you a hint of the difficulties and temptations you will encounter when, as physicians loyal

to science and modest self-respect—no science, you know, without unselfishness and modesty—you come in sharp contact with the evils of modern sham medicine. The temptation to compromise will then come with subtle but decided force. I said I would not suspect you of positive infidelity, but as science always consists in finer discriminations and the recognitions of small differences that escape ordinary observation, so, with civilization, is coming the influx of a thousand grades of deception and fraud.

The question is always suggested: How much of a quack is he? You may have no doubt about Sharp & Co.'s Safe Cure, the seventh daughter of the seventh daughter, or the pictured old man leering at you from the theatrical bulletin boards with Mephisto grin as he lovingly clasps to his arms a bottle of sarsaparilla. But how is it with the very great and the very regular Dr. Supersuspect, who writes puffs of secret proprietary preparations, or who praises one especial brand of wine—after receiving a fine case of "samples"—as a sure cure for influenza. How about Dr. Slydog, who fills his reception-rooms with hospital dummies, or who makes his patients come many times for the relief of a simple ailment, that if cured at once would result in too small a bill—or, who tells them all their symptoms are very serious, but that he has caught the disease just in time? Are these gentlemen quacks?

Dear old John Phœnix complained that our use of adjectives was entirely too vague. If a man were called good, he wanted to know just exactly how good you thought him. If "Sally who lives in our alley" should be called beautiful, is that the only adjective that could be applied to Helen of Troy? John, therefore, proposed to prefix a number to each adjective that should indicate just the degree of perfection desired. If in your calm and dispassionate opinion, Sally is as beautiful as Helen, then you would call her 100 beautiful, though perhaps your friends might think her only 25 beautiful. If we apply the principle to quacks, we have excellent results that will enable us to ticket them with a fair degree of accuracy. For instance, take the street-corner man who sells Wizard Oil with negro-minstrel accompaniment and four white stallions; he gathers a lot of money from the crowd and then drives off at a gallop; he is evidently a 100 quack, pure and simple. Take Keeley next: in order not to exaggerate, let us put him at 98 or 99. Then the Hahnemannian Knights, according to the degree of their medical education and the weakness of their potentizations, may be ranged from 95 to 75. The metaphysical Healers, being sincere but ignorant, should find their level at 80 or 70 perhaps. Where must we put the "vivopaths," the "physio-medicals," the "bio-chemicals," the "manupaths," and all the motley crowd, unnameable, indescribable? Where should we grade the cunning fellows that are clinging desperately to the coat-tails of respectability and medicine, but who are neither respectable nor medical, except in externals? Surely not under 50. Where shall be placed the fellows who receive "presents" from drug-stores and instrument-makers, who write therapeutic articles on drugs that they know nothing about, or run dispensaries as feeders for the private office? Can they come nearer than 25? Then the "brilliant-operation" men whom the newspaper reporters so easily fool, the college professors and hangers-on, who in blowing the collegiate horn pianissimo, opportunely emphasize the note of their own private and personal trombone fortissimo! In all such cases the individual conscience must decide.

Quackery may be likened to a poor artificial eye—everybody else can see through it except the patient. Strange beyond all strangeness is the gullibility of the patient—his devotion to his duper. *Populus vult decipi*—which being modernized means, the mob loves humbug.

But however disgusting, the fact is explainable. The deep-seated grudge and suspicion of the populace for scientific medicine and the secret love with which it turns toward its magic-mongering humbuggers is evolutionally but a survival of the time when medicine was nothing but magic—an atavistic return to primitive modes of thought and therapeutic superstition. And it is also profoundly pathetic—an appallingly serious fact. The scientific student of sociology watches the inrooting of institutional weeds and fruitless brush that the future civilization must grub out and burn with costly labor and sacrifice. The student of heredity and psychology sees the hardening of modes of thought and habit that must bring only pain, or misapplied or useless function. The sincere physician sees disease permeating unborn babes, and scientific progress crippled and unutilized by reason of popular perversity.

But a further explanation of the peculiar and rejuvenated power of modern medical charlatanism consists in the fact that it is not only a survival of half-extinguished medieval fires, flaming up with temporary and dying brilliancy, it is also a "combine" with modern civilized money-making and unscrupulous politics. It is not only an atavism, it is also an avatarism—present-day cupidity is engrafting itself upon ancient superstition—a marriage of medieval magic mummery and money-making so that the sly cunning of the politician uses the stupid monkey's paw to pull the chestnuts of profit out of the fire of human suffering.

Nowhere else is this fact so certainly seen as in the history and actual outworkings of that consummate example of civilized quackery called Homeopathy. An hour's study of Hahnemann's works would convince any convincible person that this sorry specimen of nineteenth-century medievalism is a disgrace to civilization; and yet it is fashionable. Laughed out of Europe, it has sought and found a home among Americans, infinitely receptive of every form of opera bouffe whimsicality and rampant rascality. If its lay adherents had the faintest conception of the hideous absurdities on which it is built, and the trickery by which it lives, they would be sickened with disgust. The distinctive principles that make it differ from scientific medicine are the following delectable Hahnemannian hocus-pocuses:

1. The cause of human disease is either the "miasm" of sycosis, of syphilis, or in overwhelming proportion, the itch.[1] With marvellous inconsistency, however, the

[1] It is sometimes said that no man could have been so asinine as to ascribe to the itch such profound powers, but using Hahnemann's own words, as quoted by that most excellent writer, Prof. Nathan Jacobson, of Syracuse (Journal of the American Medical Association, March 5, 1890), psora is the only real fundamental cause and source of all the other countless forms of disease figuring as peculiar and definite diseases in books on pathology under the names of nervous debility, hysteria, hypochondriasis, mania,

origin of all disease is held to be beyond the discovery of the human mind, supernatural, hyperphysical, a disturbance of our "dynamis" or soul life. Diagnosis of disease is, therefore, impossible, and thus the very first requisite of cure, the knowlege of the cause of morbid conditions is declared incomprehensible and scorned.

2. The more you weaken or dilute a drug, the stronger it becomes. Hahnemann's own words are: "A homeopathic dose is augmented by increasing the quantity of fluid in which the medicine is dissolved." Oliver Wendell Holmes, who has tried to drown this pestiferous sect with logic and laughter for a quarter of a century, calculates the oceans of water in which a grain of medicine must be dissolved in order to "potentize" it to suit Hahnemann. Mathematically, the thirtieth "potentization" would require a body of water equal in amount to 480,769 worlds the size of our own in which to dilute a physiologic dose of medicine. Hahnemann himself could not get it "thin enough," and so finally gave all medicine by the nose, by "olfaction," or smelling. And yet medicine so thin as this has effects that only a madman would dream of ascribing to it. A purely inert powder like lycopodium, administered in unimaginably minute doses, will, according to Hahnemann, produce 1608 distinct symptoms, covering a period of fifty days. One-millionth of a millionth of a millionth of a grain of common table-salt produced 1349 symptoms, including headache, vomiting, cardiac and lung troubles, disturbance of sight, hearing, and so on.

The method of potentization is by shaking. Hahnemann would not advise above two shakings for fear of making the dose too strong. The great apostle of homeopathy, Lutze, in an address that has reached at least forty-two editions, says that an old man was cured of persistent vomiting by means of a glass of water that Lutze had magnetized by simply holding it in his right hand.[1]

3. To cure a disease, give a medicine that in a well person would cause the disease, or something as near to it as possible—that is the holy nonsense of *similia similibus curantur*. By a grain of a drug diluted in millions of oceans of water, you are supposed to substitute a drug-disease for the natural disease; and the "instinctive vital force" will turn and "go for" the natural disease, because the vital force has, as it were, been made mad and spurred on by the drug-disease.[1]

It is worthy of this lunatic medicine that, reeking with medievalism, it should claim to be the "new school," and call "old school" that system which, by instruments of precision, bacteriology, experimental research, and a hundred scientific methods of which no homeopathist ever originally dreamed, is endeavoring to cure and prevent disease. It is worthy of this new school that it should pretend to practise Hahnemannism, while secretly using any medicinal agents and in physiologic doses. Made according to Hahnemann's theories, made as it is to-day pretended they are made, one could harmlessly eat a stomachful of their sugar pellets, supposed to be deadliest poison.

Not an instrument of precision, not a bacillus, not a ptomaïne or leucomaïne, not a single measure of genuine therapeutics or experimental research, not a single discovery of the thousands that make up the body of modern scientific medical truth and power, not one, not one was ever discovered by a homeopath. Their greatest discovery I know of is that the human iris, by its tints and fleckings and colors, denotes the parts and the particular ailments or wounds of the patient's body diseased or injured.[2] I have the recent catalogue of a homeopathic drug-store in New York, in which, to-day, among thousands of filthy things, or rather names of things offered for sale, are the following "morbific products, nosodes," etc., offered in high potencies:

"Lice insects," either of the three varieties: "serpents," "tarantulas," and "crickets." You can buy bottled sunlight, nay, the sun himself; or you have the choice of the blue rays, the yellow rays, bottled galvanism, or faradic electricity, etc. "Snow" and "ice," or "moonlight," or the "east wind," are at your command for ten cents a "graft;" it is not the germs or material particles, but the disease itself—Bright's, catarrh—any that you will; but you can also have the "pus from a carbuncle," from "Pott's disease," etc. You can buy "Brahma" himself, it seems; or, if you are sad, you can, for ten cents, have "tears of a young girl in great grief and suffering"; the "salt of the brain secreted from a gentleman's scalp with the perspiration"; a "silk handkerchief eaten by a cow and taken from the stomach in a hard ball; during the three years she never had a

melancholy, idiocy, madness, epilepsy and convulsions of all kinds, softening of the bones (rhachitis), scoliosis and kyphosis, caries of bone, cancer, varices, pseudoplasms, gout, hemorrhoids, icterus and cyanosis, dropsy, amenorrhea, hemorrhages from the stomach, nose, lungs, bladder, or uterus, asthma and suppuration of the lungs, impotency and sterility, sick headache (hemicrania), deafness, cataract and glaucoma, renal calculus, paralysis, deficiency of the special senses, and pains of every variety.

[1] He concludes "that if pure water can be so enriched in medicinal virtue by simple contact with the hand as to cure a disease of years' duration, how much more must this power grow if a properly diluted drug, whose peculiar powers experience and provings have taught, be subjected to constant shakings in the hand until it becomes enormously efficient." Further, he says: "The poisonous properties are removed from a drug through its dilution, while its special peculiarities, so to speak, its soul, remains, and by rubbing and shaking becomes vivified and strengthened by human magnetism."

[1] Hahnemann's own words again: "By administering a medicinal potency exactly in accordance with the similitude of symptoms, a somewhat stronger, similar artificial morbid affection is implanted upon the vital power, deranged by a natural disease; this artificial affection is substituted, as it were, for the weaker similar natural disease (morbid excitation), against which the instinctive vital force, now only excited to stronger effort by the drug affection, needs only to direct its increased energy; but, owing to its brief duration, it will soon be overcome by the vital force, which, liberated first from the substituted artificial (drug) affection, now again finds itself enabled to continue the life of the organism in health." The wondrous clearness, logic, and correspondence with the facts of pathology, herein displayed make the statement a fitting corner-stone for a lot of lunatics and sharpers to build a system of philosophy and medicine upon!

[2] *Die Iris, nach den neuen Entdeckungen des Dr. Ignaz von Peczely;* also, *Die Augen-diagnose des Dr. Ignaz von Peczely*, etc.; von Emil Schlegel, Tübingen, 1837. Spots in parts of the iris, according to location, mean wounds of the ear, the shin, a syphilitic tumor, lung disease, prolapse of the uterus, etc., etc.

calf." One of the most interesting and suggestive items of the catalogue is simply entitled "Omnia."

If one quotes Hahnemann or the elder homeopathists, the Hahnemannians say "this is misrepresentation," and that "in modern progress we have advanced beyond all that." And if one quotes the modern homeopathists more versed in the art of mystification, but at heart equally absurd, it is said these do not represent true homeopathy. I have quoted both ancient and modern somewhat extensively, not because I have any special grudge against this School—far from it—but because its adherents are the most numerous and coherent body of sectarians, and because they have succeeded, in this quack-ridden land, in befuddling so many people, sensible in other matters. In a simple commercial sense, I ask, would it pay to publish catalogues and offer for sale combined middle-age filth and modern rascality, if there were not buyers?

To-day there are in 53 "institutes" some 8000 pitiable victims of sin, forming four times a day in 53 lines ("jab-time") to receive from renegade medical graduates (hired servants of an ignorant charlatan trading upon the name of medicine) the hypodermatic injection of a secret substance. They are guaranteed a permanent cure of their disease, and yet a large proportion have gone through the cure more than once, and a large proportion of those never returning a second time, relapse. Despite the medical, physiologic, and literary barbarism of the Keeley pamphlets, despite the indirect fiendish cruelties of the system (to friends of patients who ruin themselves to raise the money—those who can't pay the $100 "may," as at least one of the superintendents said, "go to hell!")—despite this and the secrecy, there are men, otherwise sharp-witted and intelligent, who are crazy in advocacy of this pernicious filth. The whole affair illustrates well the popular distrust in scientific medicine, and the popular belief in a magical short-cut to health by therapeutic miracle. Young Men's Christian Associations, which would not think of listening to a scientific lecture on the results and cure of chronic alcoholism, open their doors to this monstrous guller, and the Jay Gould of the preaching business, from a supposably Christian pulpit, calls for God's benediction on the most unchristian of deviltries. With a hound's chorus of a thousand newspapers, the Chicago *Tribune* leads in this infamous exploitation of the poor drunkard. So Perkins's tractors sprang into popularity, and so, after the speedy burial of this delusion, others will periodically spring up in obedience to popular superstition, prodded and nursed by cunning Mephistophelianism. I hope soon to have some very interesting revelations to make to you about Keeleyism.

The danger of medical lunacy overtaking the people is again illustrated by the vogue of the creed of the sorry folk termed metaphysical or divine healers, Christian scientists, Faith or Mind curers. Would you think it possible that people right here in the United States, among us to-day, could believe that "it is impossible that a boil is inflamed or painful," and that "inflammation, hemorrhage, and decomposition are but thoughts, beliefs,[1] and that carcinoma, diphtheria, typhoid fever, what you will, can be cured by prayer or thinking hard at it? According to Dr. Nichols,[1] there are within the limits of only one of these curious sects about 30 organized churches, and also 120 societies that maintain regular services. Twenty-three institutes, "scientific" and "metaphysical," are advertised in one periodical! The number of practitioners "regularly graduated" reaches thousands.

Or, take another national disgrace, the patent-medicine shame. Even semi-barbarous countries have forbidden the entrance within their limits of these vile concoctions, devised to empty the pockets of the poor of money, while filling their bodies with poison. Any chemical analyst would tell you these "non-alcoholic bitters" are made up of from 25 to 50 per cent. of the vilest alcohol. Thousands of poor babes have been killed by soothing syrups—of course, containing no opium or other hypnotic—and so on, so on, to the end of the list!

What an egregious farce, that people should buy a cure-all containing they do not and cannot know what; compounded they do not know by whom—certainly not, of course, by a physician—vouched for by no one, an evident bit of hoodooism to get money—a shotgun prescription fired at disease in the abstract—an unknown remedy for an unknown disease from an unknown hand! And yet the millions upon millions of dollars invested in these nostrums, and thereby annually filched from the ignorance and want of the poorest and neediest, should arouse even the most corrupt of legislators to put a stop to it all. The superlative impudence of the villainous syndicates is degrading and wrecking the once noble profession of pharmacy, and turning the disgust of the reader and traveller into nausea by the pollution of every newspaper and of every landscape with sickening advertisements.

And now, why do Keeleyism, the patent medicine and nostrum sham, the homeopathic disgrace, and a thousand such things exist among us? They are, of course, a vital loss and a vital injury to the community, working a pollution of body upon an idiocy of intellect, by a Boss-Tweedism of ethics. Why is our country the refuge and asylum of the survival superstitions, the delirious nonsense, and diabolical financial schemes that Europe has kicked out in wrathful disgust? Simply this: the newspapers, journals, and magazines dare not tell the truth or be the means of telling the truth. Every magazine or serial depends for existence upon two sources of revenue: its subscribers and its advertisers. Let a journal or paper publish an article exposing the infamy, and "stop my subscription" would come from a few dozen people whose pet fad is that they are being persecuted, and that they, who have never studied such things a minute, know the truth about physiology and disease that thousands of scientific men have been deceived in finding. Hence no editor dare admit an article showing up the shame and wrong of these things. Physicians and other scientific men have nothing to sell, nothing to advertise; but all quacks, nostrum-venders, and patent medicine men have something to sell, and their advertisements form a tremendous source of revenue to every paper in the land. Let any journal reveal to its readers their humbuggery, and at once it is ruined.

But advertisements maligning and misrepresenting

[1] Science of Health, pp. 231, 188.

[1] Science, Jan. 22, 1892.

their opponents are put into the reading columns as reading notices, neither editor nor publisher daring to disobey the orders of the syndicates. A well-known illustration is the thousand-journal denunciation and contumely for the past year or two of the druggists who dare "substitute" for the quack medicine called for, similar and equally good preparations at one-half the price of the more advertised cure-all.

Other examples of journalistic perversity might be cited; *e. g.*, *Harper's Magazine* a year or two ago published an article by a professional humorist, claiming that homeopathy had saved modern medicine from the medieval barbarism of filthy medication and beastly therapeutics. Would it insert an article showing that the reverse is the truth, and that by the malicious and egregious blunder it had grossly insulted every physician and scientist, civilization, and truth itself?

Would the newspapers of the country, headed by the *North American Review*, give one-hundredth of the free advertising to a reputable or scientific institution for the treatment of chronic alcoholism, that they have given Keeley's humbuggery, and out of which that shrewd advertiser is making millions of dollars?

The etiology and pathology of carcinoma is certainly a deep scientific question, and yet a dashing magazine editor, who had never studied it for a minute, indorses the cure of a quack, Mattei, who had likewise not a scrap of medical knowledge, and the people are thus gulled into spending hundreds of thousands of dollars. Any medical student could have exposed the fallacy, knowing how easily tumors are diagnosticated as carcinomata, and thus often "cured." Neither Mr. Stead nor his Italian Count care for science. They have a short cut to scientific knowledge no physician could have even found out by study or pathologic investigation!

A month or two ago, a bill, "a very moderate one," and one that "the three leading and influential schools of medicine" had recommended to the Legislature of Ohio, to control the practice of medicine, was shouted down in guffaws of derision by the barbaric civilized legislators of that State at the command of the lobby controlled by the so-called physio-medicals, the druggists, patent-medicine men, and the newspapers. After this delectable piece of diabolism, this same Fejee Island Legislature—of Ohio—voted $5000 to experiment with the Keeley humbug, each legislature to furnish one Keeley patient. Doubtless with such men charity is to begin at home, and the patient will not be hard to find!

Charley Lamb said that the only way he could relieve his feelings when he heard a Gregorian chant, was to lie down on the floor, flat on his belly, and howl like a Dervish.

It is useless and tiresome to multiply examples. To the honest physician the diagnosis is easy, but to the physician himself infected with the disease and in the incubation period, the disorder is unrecognizable. He will contend most vehemently that the patient is in blooming health. All who wish to know the facts can easily learn them. Evidence of the fallacy of the popular distrust may be seen by the words of one who is certainly a competent and unprejudiced observer—the present highly honored president of Harvard University:

"It is not more than a hundred years ago that medicine claimed to have been a liberal calling, an intellectual pursuit, and even to-day its position as such is very inadequately recognized by the mass of educated men. Now, I venture to say that, as medical education is now given in the best schools, no profession has a better right to claim the title of an educated, intellectual calling, and no men have a better right to demand recognition as intellectual men, as men of trained reasoning faculties, than the physicians themselves. I see, in my position at the head of the University, which includes the department of liberal arts and several professional departments, that the educated community does not recognize this. And I exhort you, gentlemen, in all your various fields of influence to do your utmost to establish this just claim of the medical profession to the position of an intellectual calling and to establish the claim of this great body as a body of highly trained men who use to the best advantage for the community the reasoning faculty, the scientific power of the human mind."

A quack is a man more interested in himself than in the healing art; caring more for his patent than for his patient; more desirous of making dollars than of curing disease. A physician is one whose first thought is to cure his patient. This is the sharp dividing line that makes the whole matter clear.

There are those that say that medicine is a business, that the cure of diseased people and the obviation of disease is a calling like any other; that the one who cures best will do the best business—*i. e.*, get the most patients. There is but one single comment to make to that: it is a lie, and the man who says it knows he is a liar. I beg of you, if you are entering the medical profession with such ideas in your heads and such intentions in your hearts—I beg of you, leave the profession to-day. You will be poor physicians, you will die ashamed of yourselves, you will disgrace a noble calling, and you will hinder civilized progress. I assure you this universe is not put up that way! You may make some money, perhaps, but the same deviltry applied in politics or bucket shops will get you much more of the stuff you seek. We have a wretched superabundance of such fellows now to watch. A large share of the energy of good men is already used up in neutralizing their malice and thwarting their cunning. You will do far better by running for aldermen, dealing in green goods, or in anything except in the health and confidence of afflicted human beings. That is a work fitting only to those who recognize other ideals and purposes than selfishness and money-getting. The acceptance by you of your diplomas this day pledges and consecrates you to a mission among your fellowmen that is truly holy. How far you are to be above trade is clearly shown by the fact that the chemist—as near a physician as he is—can without dishonor patent drugs and reap exclusive pecuniary gain from the learning and ingenuity of his brain—but you may not do this. In a close analysis the work of the chemist and scientist is due humanity as much as is yours; every device and improvement of civilization withheld from public use or sold dearly, is trading in people's lives, is a sin against the race—but only you, yours alone of all the callings, must realize the fact in every-day life. It is a glorious honor to belong to the profession of which that can be said. But the honor only comes to them that are willing to be unknown as honored, who find the reward

in doing the work, and in the secret satisfaction of a silent, happy, and peaceful conscience.

But with the professional honor and beatitude coëxists the professional duty. There is the greatest danger that the men who believe that medicine is a business will have their way, and sink professional standing to the level of politics and trade. Will you join them or will you oppose them? The whole of your life will be the answer, and this answer will largely consist in your attitude to quackery. Dr. H. C. Wood says that as few or no homeopaths to-day believe or practise the Hahnemannian clap-trap, they have, *ipso facto*, suicided, become in a sectarian sense non-existent, and that on our part *we* may ignore the fictitious distinction and fraternize with them. The President of the Philadelphia County Medical Society advises letting them into our medical societies. A prominent weekly medical journal of New York smiles very graciously at the sectarian, and a good friend of mine, an editor of a high-standard medical journal, tells me that in his city consultations with a sectarian are very common, and go unrebuked by physicians otherwise in good standing.

In other words, after centuries of struggle and with victory in our hands—throw it away in a fit of avariciousness, cowardice, and weariness. The gentlemen quoted doubtless mean well, but the advice is unconsciously traitorous to humanity and to the medical profession. If the advice be followed, we shall fall back again into what the printers call pi, and out of this general debasement moral physicians, as individuals, will again have to raise themselves above the re-commercialized mass, and with century-long struggle, reform again a new guild, with precisely the same ideals and aims, as that we poltroons had destroyed.

It cannot escape the observation of anyone who wishes to see facts as they are, that the great mass of homeopathists, by pure necessity, have in practice entirely abandoned the whole crazy nonsense of Hahnemannian mumbo-jumbo, and cling only to the name for purely commercial reasons. The great homeopathist, Guernsey, he probably who supplied "Dr." Swan with his sample or graft of "catarrhus nasi," says that there is in New York City, to-day, no exclusive homeopathic practitioner. Any fool knows that no disease can be influenced or cured by the medieval drivel of potentizations, shakings, smellings, similias, etc. But a lot of silly women have got it into their heads that this is a "nice" and a "new" school, and these mountebanks, while giving common drugs in physiologic doses, are willing to sail under false colors for the sake of the practice it brings. It is a sickening fact, but fact it is.

What is the treatment of this veritable and terrible contagious disease—quackery? How shall you meet it? What are you going to do about it? Compromise? The suggestion recalls Hugo's famous monosyllabic fighter at Waterloo.

Instead of the ninety thousand surrendering to ten thousand, suppose the ninety thousand learn a lesson.

Combination is the order of the day in the world of trade. What is thus done for selfish reasons may be done for unselfish ones. The patent-medicine men have got every druggist and every newspaper in America in their determined grip. The homeopathists meet in National and International conventions, and devote their entire energies and time to schemes for getting State and Governmental money and aid, and for grasping every point of pecuniary and social advantage. In our lofty scorn of such low cunning, and in our intense pre-occupation with disease and its cure, we never raise a finger toward meeting such attack, never pass a resolution to set Legislatures right, never try to instruct the public in its medical duties and self-interest. If as a profession, we did but devote a tenth of our collective energy and intellect to these things, quackery would disappear. The medical profession is shut within itself. It has no means or machinery for reaching the public ear. The few thousand quacks occupy the field; the public hears from them always and emphatically.

Realize the condition of the farmer and workman, uneducated, undiscriminating. These are the bulk of our people. With almanacs and circulars and million-fold devices, the advertisements, fictitious certificates, and false promises of the nostrum-traders and the quacks reach his mind and feed it with subtle poison and plausible falsehood. The family physician is squeezed aside, and his testimony against these frauds, if he have the frankness to denounce them, is credited to his jealousy. The medical profession has scorned to devise machinery to reach these people and to open their eyes to the humbuggery. By the great mass of the people the medical profession is looked upon with contempt or ill-will, its members to be called in dire necessity, its bills paid grudgingly. The bottles of the cure-all meet the physician's eye in every household. Every State and National medical congress or organization should have a literary bureau, the local physician as the local agent, to instruct the people in physiologic, sanitary, and medical duties, and to neutralize the pernicious influences at work. It should not be held beneath our dignity to make a popular but honest and instructive medical almanac for popular distribution.

The American Medical Association and the Congress of American Physicians and Surgeons, every State and every medical society should pronounce as bodies upon the great questions affecting the health of the public. Legislators think we do not care, that we have no power. The quacks have their ears and fill them. There are a hundred great public duties we are leaving undone when, if we but spoke as a profession, medical and sanitary progress would sweep on to certain victory. It is, let us hope, only a question of time. In the riot and intoxication of the rich conquest of American advantage, Democracy thinks that every outrageous form of delusional crankery must have its swing and chance to rule or ruin. But that day is fast passing away. We must now settle down to the hard work of governing and civilizing. When the Prince Hal of Democracy becomes the King of Civilization he must henceforth scorn the Falstaffs of quackery and scatterbrained tomfoolery. So in your case when the Student Hal becomes the Practitioner King beware that you be not tempted to think that the aim of your life, professional success, will come more quickly by compromise with quackery and trickery methods. There is no doubt of the fact: if you are after quick success you will find it that way. But this plan has three disadvantages: you will not find enduring success, you will not be self-satisfied and morally strong, and you will not gain the love and honor of your fellow-men.

To be explicit and detailed, let me counsel a few "don'ts":

1. Don't be in a hurry for success.

2. Don't consult or fraternize with quacks of any kind or degree.

3. Don't be afraid of speaking out your denunciation of quackery, regardless of the loss of a few possible patients and the charge of jealousy.

4. Don't support medical journals run in the interests of the advertisers, journals that are muzzled, that are conciliatory to, or non-denunciatory of quackery.

5. Don't sign a single certificate so long as you live, as regards special, proprietary, or secret preparations.

6. Don't write a medical article in which such preparations are praised or even mentioned.

7. Don't accept commissions or presents from druggists, manufacturers, opticians, or surgical-instrument dealers.

8. Don't let any professional allusion to yourself, your opinions, or your work get into the lay newspapers. Don't be a sneak advertiser, a "newspaper doctor."

9. In your own righteous wrath against quacks outside of the profession, don't forget that there are many within the profession, and that they are the most despicable—true wolves in sheep's clothing. I would rather be the "Wizard King of Pain," and buy affidavits of impossible cures at twenty dollars each, than a respectable hypocrite indirectly or secretly hobnobbing with newspaper reporters and supplying them with "data."

As physicians charged with the health of the present and future, our duty must become clear: the entire witch's Sabbath of 'pathies and 'isms, the morbid cranks, drunk with ignorance and conceit; the sly cunning of advertising schemers, the tricks and frauds of medical parasites to suck the blood of their dupes, the patent medicine disgrace—all these things must be choked out of existence. It is a warfare, not a compromise, we are entering upon. It is not a theory, it is a condition that confronts us.

Another need is for individual instruction of people. People are wofully ignorant, medically, and we have been shuffling and cowardly. When a nice little foolish woman or a pig-headed man with arched eyebrows and self-satisfaction, tells me, "Oh, I belong to the new school," I at once say, Ach, so!—the very school I belong to—but, we differ as to what the new school really is. Excuse me, do you have the itch? Do you believe that your eau-de-Cologne gets stronger by shaking it, and that if you shake it in a peculiar manner too many times it will get stronger than aqua fortis? Do you believe your ink will get blacker, or your whiskey stronger the more water you put in it? Do "ink-grafts" and Cologne "grafts" work? Do you believe in watching the way the toe-nails grow for a year after taking a bit of vegetable carbon—toasted bread—as symptoms of disease and evidences of drug-power? Do you believe the only safe way of taking medicine is by smelling it? Did you, as a boy, find that stomach-ache from eating green apples was cured by eating green currants? If you don't believe any of these things, you are a sensible person, not a Hahnemannian. These and such things are the only things that can be called Hahnemannian. If you don't believe them, do you think it honest or manly to pretend to believe them for the sake of a few dollars, and sneakingly, hypocritically practise medicine much the same as physicians do, giving common drugs in physiologic doses?

I have been surprised to see how a few minutes' talk with such people makes it plain to them what silly fools they have been, and how egregiously they have been duped. I have looked about for some scrap of literature I could hand to these folks, to show them what roaring nonsense they unwittingly gave their assent to. Oliver Wendell Holmes's little skit is almost the only such thing. Convinced, however, that people need and will profit by simple instruction honestly, plainly, justly put before them, I wish to have a little pamphlet prepared that, historically and actually, will show up the ridiculous pretensions of modern homeopathic practice. I shall, therefore, postpone a bit of private pleasure I had planned, and offer a little prize of $100.00 for the best essay on the subject.[1]

Such a monograph supplied as a missionary tract for gratuitous distribution by physicians, at the cost of printing, would set thousands of people straight, and would soon stop the legislative and financial governmental support of this trumpery. I wish some millionaire would give me a few hundred dollars to offer as prizes for other missionary tracts, *e.g.*, on the "Patent-Medicine Evil;" "The Reasons Physicians Do Not Advertise;" "Why Physicians Do Not Patent Instruments, Drugs, Etc.;" "The Duty of the Government and State to Medicine;" "Everybody's Medical Duty;" "The Desirability of a Higher Standard of Medical Education," etc. What a disgrace that we cannot get governmental aid for payment of meat and milk inspectors, boards of health, bacteriologic and hygienic institutes, etc., etc., whilst the people's money can be filched from them to support arrant quackery. What a disgrace that patent-medicine syndicates can draw many millions every year from the diseased, deluded, and poverty-stricken of our people, with a governmental tax of only 25 per cent. upon their mixtures, whilst the same people must pay a tax of 60 per cent. upon microscopes, and one of 49½ cents a pound and 60 per cent. besides upon woollen clothing.

The physicians of the civilized world are to-day working for the public welfare with a zeal and intelligence, combined with an unselfishness that no other profession, trade, or calling can faintly rival. Think, first, that these men are almost furiously seeking by hygiene and prophylaxis to render their own calling useless and superfluous, themselves occupationless. That is a fact so strange as almost to seem unnatural in these days of self-seeking, class legislation, trusts, and combines.

Notice, again, that every instrument, discovery, drug, or invention, brought out that will do any good to

[1] An essay should not contain over 15,000 words, and in simplicity and directness should be adapted to the commonest lay understanding. Papers should be sent me on or before January 1, 1893, type-written, without the name of the author, but accompanied by a sealed letter, giving the author's name with motto or *nom-de-plume*. The essays will be given to a competent committee, and when their decision is reached the sealed letters of the authors will be opened, and the prize sent the winner. The essay will then be cheaply but well printed in large quantities, and supplied physicians at the cost of printing.

humanity, is at once and unreservedly given to the world. No physician ever patents or keeps secret any discovery or invention. Compare that with the world's way.

Reflect, thirdly, that all the world over every physician, whenever asked, gives his services to the poor without demand or without hope of compensation. Would not a lawyer, or a locksmith, think one crazy if it were proposed that he should give a large share of his time and service for nothing?

Carry the thought on. The entire tremendous labor, *for the benefit of the community*, of keeping up the enormous hospital work of all the world's cities, is borne by physicians without a cent of pay. Are there, for example, thousands of similar institutions where the poor, free of charge, can get legal counsel and help? Is there one such?

It has been the universal medical tradition, accepted without a murmur, that whosoever devotes himself to the healing art must gladly construe his duty in this unselfish manner, renouncing the usual ideals and commercial methods of the surrounding world. Beyond all question it is a fact that a like grade of intellectual capacity, the same educational preparation, and an equal amount of tireless labor in any other calling would yield a far greater financial result than is secured by the average physician. A great physician said, "If my son goes into the medical profession, I shall cut him off with a shilling." "Why so?" "Because the profession is not appreciated by the public."

It is a public misfortune, a social evil, if there is slowly, subtly, but most certainly, creeping through the profession the lethal poison of a lowered ethical standard. Every person of the land has a selfish interest in preventing our adoption of the more selfish aims and ideals of the world of trade. Business men are very short-sighted if they allow or encourage medicine to become a business. Whenever this change shall have come about (if, alas! it should), and medical success is sought by the prevalent rules of trade, then the degradation will be irreparable, one of the noblest of offices will have become as corrupted and salable as those of politics, and an engine of incalculable good to humanity will have been hopelessly wrecked.

Could one but reach their ears, how one would like to appeal, to the general public, to legislators of a serious-minded type, if such there be, to the better class of independent journals, to the more thoughtful of literary men, to the rulers and teachers in colleges and universities, to careful and prudent business men even, to patriots and lovers of humanity, all. This malicious and stupid misconception; this non-recognition of, and opposition to, the true work and worth of modern scientific medicine; this hectoring and bullying of physicians in all their aims for the public good, this cordial support of all legislative and sordid schemes of cranks and quacks—is a social menace and a common danger. It is long past the time that this suicidal debauchery should have been stopped. To all good citizens it should be protested: This is your affair, not ours. It is as much a national sin as slavery, monopoly or class-legislation, vote-buying, the liquor corruption, or city luxury—more than a sin, it is a moral disease of the body politic, and such disease is an expensive luxury. It costs untold money, suffering, and human lives. Every physician knows of many deaths directly due to quackery, but the indirect deaths and consequences are incalculable. Quackery kills thousands to hydrophobia's one. The silent scourges are the great ones—those that cut off single lives slowly but ceaselessly. It becomes for you every day more and more a question of self-protection and self-interest. It is not, as you seem to think, a huge joke, but it is your health, your life, your future, that you are trifling with. Every epidemic of any contagious disease, to put it in the crudest way, means the waste of millions of dollars of lost time, of expensive sickness, and of grievous death. In these United States hundreds of thousands of needless deaths are annually taking place—needless, because you will reach no helping hand to physicians to carry out the preventive measures, discovered and well known to us. In these same States, still other millions of years of sickness and millions of deaths are going to occur during the next few years, again because you will not aid the medical profession to search out other at present unknown sources of disease. There are plenty of possible Kochs and Pasteurs among American young men, if you cared, as they do abroad, to help find them, instead of laughing at them, killing them with indignity and distrust, whilst feasting and honoring your beloved charlatans. Are your charlatans founding institutes of bacteriology and preventive medicine? Are they trying to probe the mystery and prevent the mockery of disease? Has it been the quacks that have builded the noble new home of which city and profession are proud, for the trinity of great schools of Medicine, Pharmacy, and Dentistry, of your beloved Buffalo University? Are you wise as a nation, if, like the old persecutors, you martyrize those who are your truest, most serviceable friends? For the sake of the simplest selfishness, for the love of your children, for the sake of civilization and humanity, for God's sake, let us turn away from the folly and sin of this trifling, and enter at last upon the ways that lead to HEALTH!

THE NEED OF COMMON SENSE IN MEDICAL PRACTICE.

An Address to the Graduates of the Woman's Medical College of Pennsylvania, May 4, 1892.

BY JOHN B. ROBERTS, A.M., M.D.,
PROFESSOR OF SURGERY.

SOME years ago, about 1377 I think it was, a predecessor of mine practising surgery was constrained to write an address on "Ye Manere of Ye Leche." This, by the way, was not a treatise on the abstraction of blood in inflammation, as you might infer, but an essay on the proper behavior and conduct of a physician.

This production of John of Arderne, written about a hundred years before the discovery of San Salvador, contains much that I would say to you. My first impulse was to read his words as my own production; but I was deterred by the thought that the Latin requirement of this College insured your detecting the flavor of medievalism. I shall be content with giving you some of his advice in the language of an early translator:

"Ffirst it behoueth hym that wil profite in this crafte, that he sette God afore euermore in alle his werkis and

euermore calle mekely with hert and mouth his help. . . . . And abstene he hym fro moche speche, and most among grete men. . . . . Also be a leche no*gh*t mich laughyng ne mich playing. . . . . Haue the leche also clene handes, and well shapen naile*z* and clensed fro all blaknes and filthe."

What necessary attributes of a surgeon! Trust in God—self-restraint in deportment—finger-nails free from germs.

I hear you whisper, "Ah! but those precepts of the fourteenth century teacher were not meant for the nineteenth century woman doctor. He knew no woman physician; and, moreover, she it is that does 'abstene fro moche speche' and 'be no*gh*t mich laughyng ne mich playing.'" Be not so sure of his want of acquaintance with you; for in a certain document, dated as early as 1389, occurs a distinct reference to women practising surgery in London.

Moreover, while our ancient surgeon was living in London, Richard II became King of England; and it was during his reign that the poet wrote:

> "Twa maydens with him thai left,
> That wele war lered of lechecraft;
> The lordes doghters both thai wore
> That war left to kepe hym thore,
> Thai heled him everilka wound."

If any further evidence is needed that John of Arderne wrote his address for the ears of women practitioners, call to mind that the wounded Sir Tristram, whose deeds are told in the "Morte d'Arthur," went to Ireland where the king "made Trystram to be put in his doughter's ward and kepyng, by cause she was a noble surgeon. And whan she had serched him she fond in the bottome of his wound that therein was poyson, and soo she heled hym within a whyle."

Ireland, in truth, has always been chivalrous to women; and at a later period than the composition of the tales of Arthur, we find in the Charter of the Barber Surgeons of the City of Dublin (1446) that this Guild for the promotion and exercise of the art of chirurgery was to consist of "men as well as women." Mark the phrase "men as well as women." The men were seemingly admitted as an appendage or corollary to the women.

Having thus proved that my author's words were meant for you, I shall let him speak concerning your conduct in the sick-room and of the confidential nature of your profession.

"Also it spedeth that a leche kanne talke of gode tale*z* and of honest that may make the pacientes to laugh, as wele of the biblee as of other tragediez and any other thingis of whiche it is no*gh*t to charge whilez that they make or induce a li*gh*t hert to the pacient or the sike man. Discouer neuer the leche vnwarly the counsellez of his pacientez als wele of men as of wymmen ne sette no*gh*t oon to another at no*gh*t, thof al he haue cause that he be no*gh*t gilty of counsell, ffor *y*if a man se ye hede wele a nother mannes counsel he will wist better in ye."

He, who wrote these lines five centuries ago, was imbued with the true spirit of the physician. His surgical writings, too, show that he was no servile follower of tradition, but a thoughtful, competent, self-reliant doctor. He had that rare gift of God—common sense. Lack of this rare gift is the source of many professional failures. Knowledge of anatomy, chemistry, therapeutics, and the "ologies" is certainly requisite for true success in medicine; but unless the graduate have common sense, all these are vain. Much of the ridicule cast upon medicine springs from a public recognition of the absence of common sense in the lives of many medical practitioners. A mental attitude of calm consideration and a judicious action, never over-enthusiastic or unduly conservative, are imperatively demanded of him who essays to direct Nature's physiological processes. A successful genius may be a fool, but a successful physician never.

I beg you to remember above all things that it is your patient that is to be treated and not the disease. Some practitioners seem to retain the idea, which before they began medical study they possessed in common with the public, that each disease is an entity, which must be combated with a specific remedy. This belief, born of ignorance, assumes that the first duty of the physician is to give a name to the disease afflicting his client; the second to select from the drug-shop labels a ready-made curative medicine. Such physicians fail to realize that the practice of medicine consists in so directing vital processes that the perturbations due to disease may be lessened and finally replaced by the normal functions of health. A doctor must necessarily study at first the pathological changes underlying and causing the symptoms; he then gives a distinctive name to the disease, just as a man does to his child, not to select the remedy by which to neutralize its evil powers, but for use as a distinguishing mark. The wise physician knows, for example, that one patient with pneumonia will be killed by bloodletting; that another with the same disease will die if it be omitted. The judicious practitioner examines circulation, respiration, digestion, secretions, nervous system; and prescribes to bring aberrant tissues and organs into normal activity. He will, perhaps, give the same drug in a case of pneumonia, peritonitis, scarlet fever, or broken leg, because the patient's condition is more important than the name of the affection.

Do not think I undervalue the studies carried on by the investigator in diseased structures, whom we call the pathologist. You must all be pathologists, so as to be able to examine circulation, digestion, secretions, and nervous system. What I am trying to impress upon you is that he is an unsafe physician who, after giving a name to a disease always treats that disease with the same powder, potion, or surgical appliance. This will be clear when I remind you that one case of typhoid fever may be as different from another as inflammation of the brain is from mere physical fatigue. The safe rule of practice is the common-sense rule: "Find out what is the matter with your patient, then treat him for his individual condition." No physician can treat disease successfully without attention to the physiological characteristics of the person affected.

Let me adjure you to avoid the quackish practice of frightening your patients with high-sounding Latin or Greek names for unimportant ailments. A woman may be scared into hysterics by being told of "hemorrhage" from a pin's scratch. Call it "bleeding," and she will give it no thought. Threats of "typhoid fever" and of

"gastritis" may bring dollars into the pocket of the physician; but such tricks belong to the unscrupulous. Not very different, however, is the course of him who, because of a great reputation, charges the sick enormous fees, knowing that fear of death always assists the highwayman in the process of extortion.

It requires little time for the public to recognize the trait which I have called common sense, and its recognition is soon followed by obedience to its medical possessor. See to it that your patients are obedient. If you accept the responsibility, you have a right to demand implicit obedience to all medical advice founded on science and common sense. Gain the confidence of your clients by knowledge and honesty, and keep it by insisting upon their hearty coöperation. A patient never trusts a doctor who takes him into consultation. Many well-educated physicians have starved by reason of a fatal want of self-trust inducing them to make consultants of their patients.

A word of caution about remedies of hidden composition may not be out of place. Put little faith in the asseverations of those whose sole interest in human woe is the money accruing from man's desire to escape sickness and death. Pliny was right in reproving the physicians of the first century for buying from the Seplasiarii medicines of whose components they were ignorant. It is not in accord with the dictates of common sense to risk your patient's safety by giving an unknown compound—perhaps inactive, perhaps deleterious—because the seller vaunts its virtues in large type and with voluminous documents.

Do not forget that even the educated may give worthless evidence concerning matters out of touch with their chosen pursuits. The eloquent divine may be honestly in error when he attributes the disappearance of his gout to the bracelet on his wrist, forgetting the efficacious horse-chestnut put in his pocket months before. His evidence as to the comparative value of medicine is scarcely more convincing.

Have the good-judgment to put little faith in the certificates, signed by physicians, which are scattered abroad by makers of proprietary remedies and by venders of manufactured and natural waters. Many of these recommendations are forgeries; others are obtained from physicians who will sign almost any paper presented to them. As scientific evidence such certificates are usually worthless. Never sell your own names to such purposes, whether the consideration given be friendship, patronage, or a box of neatly packed samples.

Much of your practice will be among women, notoriously liable to symptoms dependent upon a disordered nervous system. In treating them, even more than in treating men, it is essential that the physician ever bear in mind the nervous element. Bring the unbalanced mind into subjection, and the cure will often be easy. Common sense is here the key to success. Patient investigation will show absence of serious structural disease, and firm but gentle management will bring brilliant cure. No temporizing policy is permissible in this instance; no fateful compromise may be made with the indiscriminate use of opiates or sedatives. The physician must have the iron hand in the velvet glove. Considerate tenderness, unbending honesty, and a rigid discipline will bring the doctor who dares the patient's ire absolute obedience, faithful affection, and unbounded gratitude. This sort of a physician has the spirit of the old field-marshal whose motto reads: *Erst wägen, dann wagen*—First weigh, then dare.

It is the part of caution and common sense to prescribe narcotics as little as possible, and to see to it that your patient is not informed of the administration of these seductive drugs. Many helpless opium-users and alcoholics can date their moral degradation to the garrulity of the doctor or nurse. The use of these medicines is sometimes imperative, but often a less powerful remedy will be efficacious if combined with tact and common sense. A wise old writer testifies that a certain "untoothsome composition" was "admirably well suited to the intention of an hysterick," and such can often be found, which will be of use to-day.

It has been truly said that the medical profession is not one for untrained hearts and feeble brains, because it demands the devotion of a lifetime, the possession of ability, and a training which only the amplest opportunities can insure. The responsibilities put upon a doctor are somewhat similar to those assumed by the clergy, and the daily dependence of life upon the judicious character of his acts makes his function full of anxiety and care. No citizen has more capacity for rendering service to the State and his fellow-men than the educated physician. His special knowledge of the secrets of the human laboratory and his intimate acquaintance with the peculiarities of human nature give him incalculable power over the destinies of individuals.

We, your instructors, have endeavored to teach you the science of medicine—medicine founded on physical and physiological truth; and in that effort have aimed to show you how to observe and how to think. All the resources of science are to be pressed into your service. In the selection of methods of treatment, in the choice of drugs and their doses, you are bound to no authority, sect, or dogma. You are at liberty to use the infinitesimal dose, or the tangible pill; the remedy obtained from the vegetable kingdom, or that of mineral origin; the so-called current of the electrician, or the hypnotic influence of the strong over the weak mind. You are neither allopath, homeopath, electropath, nor hydropath. You are simply physicians, whose educated hands must draw upon every department of mental and physical science in the attempt to relieve and cure. Your teachers only ask that you prove all things and hold fast that which is good. Let your practice be founded on common sense and conscience, and then no folly, no evil, can be justly laid at your door.

You have to-day received your diplomas from a Medical College that for years has required more months of attendance on lectures and laboratory work than any other medical school in this great State of Pennsylvania, a State noted for the excellence of its medical institutions. It is gratifying to tell you that in October of next year will be inaugurated the compulsory four years' course, requiring your successors to attend four annual courses of graded medical lectures before being eligible for the degree of Doctor of Medicine. This advance and the additional requirements in the entrance examination, show you that the Woman's Medical College of Pennsylvania intends to be ever in the vanguard, and that you need have no fear of your alma mater

debauching the profession by lowering the standard of medical education.

The Corporators and Faculty need, however, your help—the help of all the alumnæ—to increase the endowment of the school, that additional opportunities for clinical study and for laboratory work may be provided, and that a healthy mind in a healthy body may be obtained by systematic and scientific physical training in a well-conducted College gymnasium.

My words may convey to you the impression that the life upon which you now enter is not an easy one. It is true. The daily work of a doctor is hard; but it is one full of deepest satisfaction; and in the words of Canon Liddon, physicians "have some part of their reward, at any rate, in a homage which neither wealth nor birth can possibly command." The knowledge of your usefulness to the public and of your ability to aid and support those in sorrow and despair is a thing that cannot be taken from you.

Worldly success, too, is sure to come to the educated, earnest, reliable doctor. An example is seen in that physician of whom a distinguished writer has recently said: "He owed our unbounded trust not to his intellect, which was not highly originative or fitted for profound research, but to a singular balance of mental and moral qualifications. Novelties neither too much tempted nor too much repelled him. He was intellectually very honest. . . . . I never knew a man who seemed to me to live his professional life on higher levels of that common sense which in its perfection is so uncommon."

Compare this quotation, giving the most valuable characteristics of the successful modern physician, with what our author of the fourteenth century tells us of "Ye Manere of Ye Leche"; and you will see that success and reputation depend now, as then, upon much the same traits.

An even older writer tells us, "In quietness and confidence shall be your strength"—First weigh, then dare, —and the esteem and commendation of your fellows, the approval of your own consciences will follow the recognition of duty nobly done.

Time, however, will not allow me to dwell on my theme, for "many thingis forsothe bene to be kept of a leche withoute these that ar seid afore that may no*ght* be noted here for ouer moche occupying."

MEDICAL PROGRESS.

Osteo-medullary Lesions of Mammary Carcinoma.—SNOW (*British Medical Journal*, No. 1628, p. 548) directs attention to two phenomena that he considers characteristic of the early stages of non-atrophic carcinoma of the female breast. One of these he designates the "sternal symptom," which consists in a prominence at the junction of the manubrium and gladiolus, whence it extends. It is occasionally attended with tenderness on pressure, and is ascribed to decalcification of the bone, with softening and deformity, together with some degree of hyperemia of the periosteum, dependent upon carcinomatous infection. The second physical sign, which is called the "humerus symptom," is relative thickening of the upper epiphyseal extremity of the humerus on the same side as the diseased breast, with deeply-seated gnawing and tenderness on pressure, likewise dependent upon infection by carcinomatous cells and secretions.

Chloroma.—HÖRING has reported a case of chloroma, a rare form of tumor, in a child six years old. The growth occupied the head and neck in the left parotid and submaxillary regions. The base and convexity of the skull, the lungs and the bronchial glands, and the kidneys and some mesenteric glands, were also involved. The pigment of the neoplasm was contained in the cells, and appeared as greenish granules, yielding the reactions of fat. Histologically, the growth consisted of a fine reticulum containing small, round cells, lymphocytes, that stained deeply and were deficient in protoplasm, together with some spindle elements. Höring considers the chloroma as a form of lymphoma, and proposes the name chlorolymphoma.—*Centralbl. f. klin. Medicin, 1892, No. 10, p. 186.*

The Unity of the Hematozoon of Malaria.—VINCENT (*Comptes-rendus Hebdom. des Séances de la Soc. de Biol.*, 1892, No. 12, p. 255) examined the blood in fifty-nine cases of malarial fever of various forms, and is led to accept the unity of the hematozoön. Spherical or ameboid bodies were found in all cases. In two cases flagellated bodies were present; in thirty-one, rosettes; in four, crescents. Crescents were found in the blood in two cases of recent intermittent fever; while in two ancient cases of irregular type ameboid bodies were found, but no crescents. In the same blood in each of a number of cases were found rosettes composed of a varying number of segments, from seven to twelve; nor did the number of segments and the shape of the organism always correspond with the type of fever.

Recovery from Three Ounces of Tincture of Opium.—BURGESS (*Dublin Journal of Mental Science*, April, 1892, p. 270) has reported the case of a woman, thirty years old, who, after taking three ounces of tincture of opium, presented profound symptoms of poisoning, the breathing for a time ceasing. Energetic treatment, however, including stimulation by electricity and otherwise, injections of atropine, and especially artificial respiration, pursued for seventeen hours, was finally followed by a gradual restoration of function, with eventual recovery.

The Pathology of Exophthalmic Goiter.—At a meeting of the Berlin Society for Psychiatry and Nervous Diseases, MENDEL (*Centralbl. für Nervenheilk. u. Psychiatrie*, February, 1892, p. 5) reported that in a case of exophthalmic goiter in a man, forty-eight years old, there was found after death no abnormality in brain, vagus, or sympathetic system. In the medulla, however, there was atrophy of the left restiform body and of the right solitary bundle.

Influenza Followed by Chorea and Death.—MCCARTHY (*Lancet*, No. 3579, p. 745) has reported the case of a woman, sixty-five years old, in which in the course of a protracted attack of influenza choreic movements in the right upper extremity and in the face appeared. Speech was interfered with. Despite active treatment, the woman grew progressively worse, until death occurred.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,
1004 WALNUT STREET,
PHILADELPHIA.

Subscription Price, Including Postage in North America.

PER ANNUM, IN ADVANCE . . . . . $4.00.
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, MAY 7, 1892.

WORD-BLINDNESS.

OUR knowledge of the remarkable variety of sensory asphasia known as word-blindness has of late years become much more definite and accurate. In the majority of instances, the condition has been associated with a lesion of the supra-marginal and angular gyri on the left side. It may exist with or without mind-blindness—that is to say, with complete inability to read, the patient may perfectly understand the relation and nature of objects and things. Word-deafness and word-blindness not infrequently coëxist.

In a recent study of considerable interest, DEJERINE contends that there are two different varieties of word-blindness. In one, the patient is incapable of reading either printed or written characters, and is incapable of writing either spontaneously or from dictation; in the other, although the patient is unable to read, he writes easily and correctly, either spontaneously or from dictation. The first form, word-blindness with agraphia, may exist alone, but is not infrequently accompanied by other manifestations, such as motor aphasia, paraphasia, or even word-deafness. Of uncomplicated cases of word-blindness with agraphia, several instances of great interest have been reported, in which the lesion has been accurately limited to the angular gyrus (*pli courbe*) on the left side. This symptom-complex of word-blindness with agraphia, associated with an accurately limited lesion to the *pli courbe* is opposed to the existence of a special graphic center in the brain, placed by CHARCOT and by EXNER at the posterior part of the second left frontal convolution.

In the second variety, which DEJERINE calls pure word-blindness, the power of writing spontaneously and from dictation is retained. The act of copying is, however, difficult. In a remarkable case, studied with great accuracy by DEJERINE, the localization of this form of word-blindness has been determined. The patient, a man, aged sixty-eight, extremely intelligent and cultivated, was for a period of four years the subject of total word-blindness, being unable to read written or printed characters, and though a musician he had lost entirely the comprehension of musical signs. As has been noted in one or two other cases, he retained, however, the power of reading figures and of calculating. There was no trace whatever of motor aphasia, nor was there any word-deafness or mind-blindness (apraxia). The power of spontaneous writing and of writing from dictation was perfectly preserved, and he could write correctly pages of manuscript. Copying could be performed, but with difficulty. There was right lateral hemianopsia with hemiachromatopsia. This condition persisted for four years, during which time the patient remained in good health, showing no signs whatever of any motor or sensory disturbance, or of word-deafness. He was intelligent, and able to attend to his affairs. An attack of loss of consciousness was followed by paraphasia and total agraphia, and in ten days by death. Old lesions (yellow softening) existed in the occipital lobe, involving the lingual and fusiform lobules, the cuneus, and the tip of the occipital lobe, with marked atrophy of the fibers of the optic radiation. There was recent red softening in the inferior parietal lobule and the angular gyrus. The old lesions in the occipital lobe explain the hemianopsia, and DEJERINE offers the following explanation of its relation to the pure word-blindness: "On account of his right hemianopsia the patient no longer saw the letters with the left hemisphere, but only with the *right half* of each retina, as the right hemisphere was intact. He saw the letters simply as any other signs, and copied them as such, but they had no meaning for him, because the con-

nections between his two common visual centers and the visual centers for words in the angular gyrus was interrupted. This latter center was not injured, as shown by a study of his internal speech (*language intérieur*), from the absolute integrity of spontaneous writing and of writing from dictation, and from the fact that optic images of letters could again be revived by throwing into action his muscular sense, by making him trace in the air the outlines of letters with either the left or the right hand. With regard to the disturbance in copying, it is easily explained by this interruption in the connection between the angular gyrus and the two occipital lobes."

"CHRISTIAN SCIENCE" IN CHICAGO.

THE *Chicago Inter-Ocean*, in defence of a "Christian Scientist" who has been prosecuted on account of the death of one of her victims, indulges in the following lucid and forcible comparison:

"It has been said in behalf of homeopathy that if the remedies do not cure, neither do they kill. The worst that can be said of them is that they let the patient die a natural death. The same can certainly be said of the so-called 'Christian Science' treatment. And in reality, does it not look as reasonable that mental treatment should be as effective as the infinitesimal medicines of Hahnemann? Does it not look just as reasonable that a strong mind, trained for mental healing, should be as efficient in a case of typhoid fever as the 160th trituration of arsenicum further diluted in a half-glass of water and given to the patient in teaspoonful doses every hour? . . . .

"Homeopathy stands to-day face to face with allopathy on the same plane, fully sharing in the public confidence and respect. But it is just as difficult to understand how a single grain of a remedy infinitesimally divided and given in successive doses can cure a disease as it is to understand how the trained mind, determined on doing the same thing, can accomplish the purpose."

As allopathy does not exist except in the imagination of homeopaths and those whom they have succeeded in hoodwinking, there is nothing in the letter of what we have quoted with which we cannot agree; nor are we entirely sure that the editor of *The Inter-Ocean* is incorrect when he claims that those who desire to commit suicide by the method of Christian Science "have the right to exercise that choice without let or hindrance from the public."

Three points, however, seem to have been overlooked by *The Inter-Ocean:* First, that where the representation is made of ability to cure, and money or other valuable consideration received, the criminal offence of obtaining money under false pretences is committed. Secondly, that in cases of epidemic or contagious diseases, the safety of the public is involved, and that, therefore, the law has a right to interfere. Thirdly, that while, in some States, everyone has the right to commit suicide, in no State has anyone the right to commit homicide; and that, therefore, although the entrusting of one's own life to Christian Science healing may be justified on the ground of saving the fool-killer unnecessary trouble, yet it is certainly a crime to endanger the life of another—wife or husband, parent or child. On these grounds society is also entitled to interfere with that "free exercise of choice" so dear to the heart of *The Inter-Ocean.*

THE TEMPERATURE IN INFLUENZA.

INFLUENZA has been so thoroughly discussed that it would seem as if its symptomatology were completely written. Many of the symptoms of the disease are most readily explicable upon a neural basis, while the recent discovery of a specific bacillus, together with the knowledge of the intoxications that usually follow in the train of bacterial infection, gives support to such an explanation. In a given case, pulmonary, gastric, intestinal, cardiac, cerebral, or spinal symptoms predominate, as the nervous apparatus of one or the other system bears the brunt of the disease. The course of the pyrexia presents no special characters. As a rule, the temperature rises to its highest at the beginning or early in the attack. Not uncommonly the elevation is preceded by a rigor. In the course of the disease the temperature pursues a continued type, in some instances subsiding by lysis, in others by crisis, sometimes attended with sweating. In some cases, however, the pyrexia has pursued a most unusual course. Thus, KORNBLUM (*Zeitschrift f. klin. Medicin*, 1892, xx, 1, 2, p. 160) describes a form of intermittent influenza in which the temperature presented irregular exacerbations, with aggravation of the general symptoms, and remissions with corresponding amelioration. There are also some observations of subfebrile temperature in the course of influenza. Thus, S. SOLIS-COHEN (*Philadelphia Hospital Reports*, vol. i, 1890, p. 162; *Therapeutic*

Gazette, March 16, 1891) describes coldness of surface, enfeeblement of circulation, tendency to collapse, and prolonged subnormal temperature as common in cases of influenza. In one case, the subnormal temperature was the only objective sign of disease. This observation has been confirmed by VINTRAS (*British Medical Journal*, No. 1629, p. 601), who found the temperature subnormal in the period of depression following the acute stage of influenza; and ELLIOTT (*British Medical Journal*, No. 1630, p. 682) adds testimony of like character. In the current issue of THE NEWS, in the report of the proceedings of the American Pediatric Society, EARLE, of Chicago, is quoted as having made a like observation in children. The lesson to be learned from the facts recorded is that influenza is a depressing disease in which the vital powers are to be sustained and elimination of noxious matters encouraged, while depressing remedies of all kinds are to be sedulously avoided.

REVIEWS.

A TREATISE ON DISEASES OF THE LUNGS AND PLEURA. By the late WILSON FOX, M.D., F.R.S., Fellow of the Royal College of Physicians; Physician-in-ordinary to her Majesty the Queen; Holme Professor of Clinical Medicine at University College, London, etc. Edited by SIDNEY COUPLAND, M.D., F.R.C.P., Physician to the Middlesex Hospital. 8vo., pp. xxxii, 1200. With portrait frontispiece. Philadelphia: P. Blakiston, Son & Co., 1892.

FROM the sympathetic preface of the editor, we learn that this treatise comprises the main literary labor of its lamented author. The delay in its publication has been due to its extent and the necessity of making it represent the knowledge of the day. It remains, however, substantially as its author left it. There have been no excisions of the text, and all of the author's opinions have been retained, the editor having merely made certain additions rendered necessary by investigations and discoveries since Dr. Fox's death.

The editor is fully justified in saying that, from the time and pains expended by the author in its production, and the amount of knowledge that it contains, this work occupies a unique place in English medical literature; that its striking characteristic is thoroughness, and that the author's extreme fair-mindedness in dealing with the work of others stands prominently out in its construction. There is hardly any fact for which some authority is not cited, so that in this praiseworthy effort to do justice to others the author hardly seems to have done justice to himself. Nevertheless, it is evident that the present work contains much that is original and the result of independent thought. We heartily commend to medical writers in general the following trenchant remark of the editor's: "There are some whose originality lies mainly in their ignorance of the work of other men; there are others who, like Dr. Wilson Fox, aim solely at the declaration of the truth, and are anxious above all to give credit where credit is due."

The articles on Emphysema, Bronchiectasis, Pulmonary Embolism, Intra-thoracic Tumors, and Gangrene of the Lung are by far more detailed and exhaustive than in any other existing English treatise.

The elaborate articles on Pneumonia, Broncho-pneumonia, etc., first appeared in Reynolds's *System*, but they have been thoroughly revised, with the exception of that on Chronic Pneumonia, which was left untouched. There is no means of knowing whether or not Dr. Fox had intended to re-write this article.

To properly review this book in the space at our command would be a hopeless task. The work shows patient, persistent, faithful study from books, from patients, at the bed-side, and from diseased organs after death. Each page is replete with information, much of which can scarcely be found elsewhere without prolonged search through monographs and forgotten treatises.

Such books as this of Fox's, as Fagge's *Practice*, as Gowers's *Diseases of the Nervous System*, as Brunton's *Pharmacology*, seem to be produced only by English physicians. They are not only scientific, like the German; interesting, like the French; practical, like the American—and scientific, interesting, and practical at once—but they bear the marks of thorough training in observation and in the recording of cases, brought to bear upon a richness of material such as seems hardly to be rivalled outside of London.

To attempt to criticise the author's views without first fully setting them forth would be worse than useless, and we can only heartily and thoroughly commend the book to the careful study of every English-reading physician whose aim it is to be thoroughly informed as to the progress of his science and his art.

A MANUAL OF DISEASES OF THE NERVOUS SYSTEM. By W. R. GOWERS, M.D., F.R.C.P., F.R.S. Second edition, revised and enlarged. Volume I. Diseases of the Nerves and Spinal Cord. Philadelphia: P Blakiston, Son & Co., 1892.

ALTHOUGH several works of importance have appeared since the first publication of the treatise of Dr. Gowers, it has held its place for six years, as the clearest, the most complete, and the most trustworthy textbook on nervous diseases in any language. The present edition has been both revised and largely re-written, containing many additional pages of valuable matter. It is, indeed, extraordinary how much personal experience and work the author has incorporated in this manual; it is by no means simply a compilation.

The discussion of peripheral neuritis in the first edition presented this subject more fully and clearly than any other work, general or special, and deserved prominence has been given to the same subject in the present edition, new sections bringing its consideration up to date. The diagnosis of multiple neuritis is thoroughly and carefully considered, and special attention is called to the necessity of determining whether the spinal cord is concurrently affected with the nerves. The account of syringomyelia, although not lengthy, is complete and comprehensive, and contains also the re-

sults of the observations made since the publication of the first edition. In a brief notice of a second edition, however, it will not be expected that we shall review at any length the merits of particular chapters. The new edition more than sustains the high appreciation which was extended to the book on its first appearance. We can say of this work what can be truthfully said of but few professional text-books, that it is adapted to the uses of the student, the general practitioner, and the specialist.

This treatise proves clearly that the day of great text-books written by single individuals has not altogether passed away. The present is an era of monographs and of "Systems"; but one great defect in the latter is the tendency to unevenness, both of quality and quantity, in the consideration of different subjects—long and elaborate articles are furnished upon certain topics, while others, perhaps of nearly equal importance, are discussed in a short and incomplete manner; and chapters well digested and carefully prepared are found side by side with rambling compilations. This text-book, written by one who is a master of lucid style and of the specialty which the book considers, is free from this great fault.

We believe that a book of the size of the present treatise is better presented in two volumes than in one. The present publication, which is the first volume of the Manual, includes diseases of the nerves and spinal cord, and gives with the index about 600 pages; the second volume will deal with diseases of the brain, and general diseases of the nervous system. We trust that the American publisher will keep the book in two volumes.

In concluding this brief notice we need only say that we believe that this great *Manual of Diseases of the Nervous System* will outlast in popularity and length of years nine-tenths of the text-books and systems that have appeared during the last decade.

Diseases of the Eye. A Handbook of Ophthalmic Practice, for Students and Practitioners. By G. E. de Schweinitz, M.D., Professor of Diseases of the Eye in the Philadelphia Polyclinic, etc. With 216 illustrations and two chromo-lithographic plates. Philadelphia: W. B. Saunders, 1892.

This excellent work of Dr. de Schweinitz and of Dr. Wallace deserves a hearty measure of praise. It is hardly too much to say that for the student and practitioner beginning the study of ophthalmology it is the best single volume at present published. The parts pertaining to diseases of the eye are exceptionally good, though there is sometimes evidence of a somewhat hasty walking over rough places with perhaps too easy a stride.

The chief criticism that occurs to our mind is against a sin of omission evidently committed with the completest forethought and intention: the scorn of what the author, if he were absolutely frank, would probably designate as the childish or even contemptible enthusiasm of some ophthalmologists as regards the effects of "eye-strain" and the reflex symptoms reported as due to ametropia. In the entire work the term eye-strain or its equivalents, with the resultant symptoms, are hardly mentioned. Headache is alluded to as a symptom of heterophoria. The sneer is scarcely veiled in the unwilling admission that cure of the "host of other complaints" has followed the correction of the ocular difficulty, but it comes out pretty plain in the snapper-end of the sentence: "There is also no doubt that the whole matter has not always escaped exaggeration."

In an ophthalmologic treatise issued in this country and in Philadelphia in 1892, it seems a little strange that among the "symptoms" of hyperopia and of astigmatism not a single reflex symptom, not even our beloved headache, is even mentioned. This method of exposition may be very pleasing to a few general physicians and neurologists who long ago settled the matter in their own minds, but it may be politely protested that such settlement will hardly stand the tests either of time, of truth, or of a more unprejudiced court.

We marvel that American authors and publishers continue to use an antique style of orthography that all the splendid philologic talent of American lexicographers has united in condemning. There is, moreover, self-inconsistency here: why write *hemorrhage*, and on the same page *hyperæmia*. It is time we were done with *anæmia*, and *centre*, and *anæsthesia*, etc.

Did Dr. Wallace really mean that his chart (p. 171) is in the illustration reduced only one-sixth?

The causes of ametropic choroido-retinitis, as set forth in the original paper of Dr. Gould, were not limited to (ametropia and) insufficiency of the internal recti muscles. Heterophoria of any type may produce it.

The terms "with the rule," and "against the rule," as applied to astigmatism, are used, but, if we do not err, are nowhere explained.

Seancé (p. 555) is one of but very few typographic errors noted.

The index is sadly incomplete.

CORRESPONDENCE.

FILTH-DISEASES.

To the Editor of The Medical News,

Sir: In the issue of The Medical News of March 19, 1892, Dr. Charles V. Chapin, of Providence, expresses his views in an article entitled "Are Typhoid Fever and Diphtheria Filth-diseases?" It seem to me that the writer lays himself open to criticism in conferring upon his article such a title as the foregoing, for the reason that a cursory reading of the paper might imbue the mind of a busy reader, whose time is precious, with a lingering suspicion that *filth* may not be the extremely dangerous factor in diseases of this nature that bacteriologists and health boards contend.

The paper is an interesting one as demonstrating how far one may expect to find individual cases of such diseases depending on the sanitary condition of the *houses in which they occur*. That such diseases do not depend on filth the paper does not prove satisfactorily, for the writer's own admission in concluding his article is as follows: "It seems to me that diphtheria and typhoid fever are not filth-diseases, in the sense in which the public understands that term, except in a very limited degree."

Are we to understand that the writer thinks the public over-educated on the subject of filth; that he thinks it

would be well to depreciate to the public the dangers of filth; or, that he thinks the dangers arising from filth are over-estimated by the profession?

In the opening sentences of the article, the writer states: "The causative relation of filth to disease is a theory based in the first instance, it is to be feared, on the too careless inference drawn from data not sufficiently investigated and understood." Certainly the writer cannot hold the same understanding of the definition of "filth-diseases" as do the majority of the people.[1]

He states that "not all germs are pathogenic. In fact, the great majority are not, and this is particularly true of those found in decomposing material—*i. e.*, filth;" and in the next few lines, that "it is not filth in the sense of dead and decaying organic matter which is dangerous, but only such matter when it is the seat of growth of specific pathogenic organisms." Filth composed of dead and decaying organic matter may or may not be dangerous. I should like, however, to recommend inquiry as to how we can determine just what individual samples of filth do, or do not, contain disease-germs, or how we can know that *any* filth does *not* contain disease-germs?

The germs of typhoid fever and of diphtheria not only find a lurking-place in filth, but they luxuriate and multiply in it.[2]

The presence of the germs of diphtheria and of typhoid fever in the human system is but an epoch in their life-history—simply an incidental method of vegetating and multiplying. Such growth and multiplication mean disease and perhaps death to the human organism, thus made a means of furnishing fertile soil for their development; but the germs so propagated continue to live, and, if under favorable circumstances, to thrive, after their exit from their temporary habitat in the human organism.

On the other hand, filth is dirt,[3] and in the connection in which bacteriologists use the word, I take it to include sewerage, decomposing organic material of either vegetable or animal nature, organic dust, contaminated sewer-gas, water containing in solution any appreciable amount of organic matter. In all such, disease-germs may lurk, and, under suitable conditions, may grow and multiply. The fact that all germs are not pathogenic does not in any way justify us in countenancing filth because the great majority of germs found therein are not pathogenic.

No one now considers that from filth, pure and unadulterated, any abiogenesis of typhoid fever or of diphtheria germs ever takes place.

Over fifteen years ago, Prof. Tyndall, after elaborate experiments proving the truth of his assertions, said, in regard to the propagation of bacteria: "No change of any isolated organism into another organism is ever observed. The bacterium remains a bacterium; the vibrio, a vibrio; the penicillium, a penicillium; and the torula, a torula. Sow any of these in a state of purity in an appropriate soil; you get it, and it alone, in a subsequent crop. In like manner, sow smallpox in the human body, your crop is smallpox. Sow typhoid virus, your crop is typhoid; cholera, your crop is cholera. The disease bears as constant a relation to its contagium as a thistle does to its seed."[4]

The cause of every case of typhoid fever should be thoroughly sought for; and because it may not be found, the idea that it has arisen without cause should not be countenanced for a moment. There is a cause, and the problem is to find it. The more difficult it is to find, the more safely, other things being equal, may we attribute its dissemination to filth. Germs of these diseases lurk in filth, and because pure air and sunlight are detrimental to their life and growth, they lurk in perhaps no other place so securely and constantly as in filth; and, therefore, such cases of disease as are generated from that source are called, and, in our humble judgment, properly called, "filth-diseases."

Again, would the writer have us understand that by "bad sanitation" he means a bad condition of isolated houses taken into consideration individually, and not conditions of filth-accumulation in vaults, cesspools, wells, or even the water supplied by a conduit that might have a common causative relation to disease? If he would not have us so understand him, what is expressed in the following sentences? "If where typhoid fever and diphtheria are found, bad sanitation is much more prevalent than in other dwellings near by, we would have good reasons for suspecting a causative relation. But if not, we would be required to seek very strong evidence elsewhere to show that these are filth-diseases."

Would not the position of a health-officer lead one to inquire into the condition of all surroundings of a case of either of these diseases that *might possibly* furnish the contagion, whether it involved a distance of yards or of blocks?

It is known that wells may be infected by filth contaminated with such disease-germs for a distance of at least several yards, and water supplied by conduits may be infected at a point miles away from its final destination. Certainly to most medical men "bad sanitation" means more than the poor plumbing of individual houses under consideration; and they would consider a water-supply contaminated by filth containing disease-germs (the relation of water-supply to typhoid fever is not referred to), a much more prominent instance of bad sanitation.

Again, we should be pleased with experiments or data going to show that "there is no evidence of any relation between scarlet fever and filth," for which statement the writer gives no authority except his own. In the light of recent revelations in bacteriology, and in the presence of its beneficent influence on the public health, the depreciating of a possibly too ardent enthusiasm in its study seems to me somewhat ill-timed; for though the paper in question might lead some superficial reader to believe that filth is not the dangerous factor in our civilization that it is proving to be, yet I think we need not fear that the paper may put any check to the overwhelming flood of evidence that filth and disease are almost synonymous.

Dr. Bayard Holmes well expressed the ideas most

[1] Century Dictionary, p. 2217: *Filth-disease*, a disease caused by or arising in consequence of filth.

[2] T. Mitchell Prudden: Story of the Bacteria, p. 84. THE MEDICAL NEWS, Feb. 27, 1892, p. 249.

[3] Webster's International Dictionary, p. 560.

popular with the profession in this regard, when he said: "It will soon become as embarrassing to say, 'I have just recovered from an attack of typhoid,' as to say, 'I am just getting rid of the itch.' As the family was the unit that perpetuated and exterminated the itch, so is the community the unit that perpetuates and must exterminate the filth-diseases."

It cannot be, I think, that filth may soon become too much feared by the public, or that it may be unjustly stigmatized by coupling its name with disease by our present method of designating such afflictions as "filth-diseases."

Yours very truly,

WILLIAM C. BRAISLIN.

BROOKLYN, N. Y.

INFLUENZA IN EASTERN MONTANA.

To the Editor of THE MEDICAL NEWS,

SIR: The altitude of this part of the Yellowstone Valley is about three thousand feet above sea-level, and if there is a difference in the picture here drawn and its counterfeit presentment in lower regions the atmospheric conditions are responsible.

Judging from a description of the physical geography of Russia, influenza finds in parts of our State a field for exploitation comparable to its European habitat.

There are seemingly distinct varieties, according to the temperament. The nervous type is the prevailing one. Intense headache, deafness, neuralgic pains, catarrhal symptoms, are common. Among children pseudo-whooping-cough, either as a sequel or concomitant, occurs. At the onset, convulsions, followed by protracted delirium or unconsciousness, have often been recorded. Membranous enteritis in children and adults is much more frequent than usual.

A middle-aged Massachusetts woman, who had carcinoma of the breast in abeyance, on coming to this section was stricken with influenza, the malignant disease rapidly progressing to a fatal termination. She first experienced the usual difficulty so common to newcomers. More lung-tissue must be brought into active play to aërate the blood properly. Corset-wearing and indoor life make the abnormal lung-expansion exceedingly difficult, and hence women do not become acclimated as soon as men. In the case in question, the necessity of employing the accessory respiratory muscles aggravated the carcinomatous disease.

The use of strong drink is perhaps more common in Montana than elsewhere in the Union. Insurance companies are obliged to let down the bars to some extent on the question of alcoholic indulgence, in order to do business in the State. It was a common practice for men who found themselves contracting influenza to fill up on whiskey. When the patient had previously been abstemious, alcohol did not act as a prophylactic or an abortifacient of the disease. In habitual drinkers it was decidedly indicated.

Interference with pregnancy was common, together with a condition well described by Professor Da Costa as resembling typhoid fever, with a rather high and continuous temperature. No fatal results have been noted as a result of this complication. Cases of rheumatism have been more common than usual. Syphilis is a common visitor to the physician's office, but no cases of influenza in association with primary syphilis have turned up. Social conditions make venereal diseases more common than the census would indicate. Just across the Yellowstone River is the Crow Indian Reservation. The squaws are notorious for their filth and unchastity. Not a single case of influenza has been under observation in an Indian.

A young married woman, about twenty-eight years old, gives a history as follows: Succeeding the influenza, she is obliged to wear glasses for near-sightedness; has partially paralyzed lower limbs; cannot walk without dragging the toes, and has lost the power of having sexual intercourse.

Chorea, followed by obstinate incontinence of urine, occurred in a girl ten years old, after the influenza. Death from chloroform-narcosis in a young, unmarried woman happened at a dentist's office in February, 1892, the supposed cause of which was the influenza. Half an hour after death, while artificial respiration was being performed, one pupil was widely dilated and the other contracted.

Taken altogether, influenza on the table-lands of the Rocky Mountains has been a formidable enemy to health.

Respectfully,

JAMES E. FREE, M.D.

BILLINGS, MONTANA.

PETROLEUM-EMULSION FOR SKIN-DISEASES.

To the Editor of THE MEDICAL NEWS,

SIR: For some time I have been employing a coal-oil emulsion as a local application in eczematous and other skin-affections attended with itching. It does not obtund the sensibility of the hyperesthetic tissues in manner and degree like carbolic acid, but it is free from the unpleasant odor of the latter. As an excipient for some of the usual skin-medicaments it may be used advantageously. Alone, it varnishes and soothes the sensitive surface, and if not always curative it is at least a valuable adjuvant to other treatment. Besides being quite innocuous, it is, in my opinion, anti-microbic and is unaffected by lapse of time and contact with the body.

Among those for whom I have prescribed it in connection with other treatment, I venture to quote an Iowa physician, who wrote me February 3d, last, that he had been a victim of papular eczema for years. Under date of April 4th he further remarks: "I thank you for the interest you took in my case and for the good advice you gave. I find petroleum-emulsion the best of anything I have used. It quiets the itching for a time; it forms a nice protective sufficient to keep my clothes from irritating; and besides, being cleanly and not offensive, is easily washed off. I am quite well and think my improvement has come from constitutional more than local treatment." (Linen or cotton should have been used to cover the application.)

I need not remind your readers that in many affections of the skin, as in the case narrated, there may be a diathesis, rheumatic or otherwise, which will demand systemic as well as local treatment. Meanwhile, a placebo, with all that the name implies, is an important desideratum.

Respectfully,

C. M. FENN, A.M., M.D.

SAN DIEGO, CAL.

SOCIETY PROCEEDINGS.

AMERICAN PEDIATRIC SOCIETY.

Fourth Annual Meeting, held at Boston, May 2, 3, and 4, 1892.

FIRST DAY—MAY 2D.

THE President, DR. WM. OSLER, of Baltimore, delivered the Annual Address. After returning thanks for the honor conferred upon him, he spoke of the necessity of specialism in America, and also of the benefits accruing to the general practitioner, as well as of the necessity of thorough preliminary training and devotion to the selected calling. Too little attention has hitherto been paid to the diseases of children. Hospitals and clinics may enable the student or practitioner to acquire proficiency in the necessary technique. Post-graduate schools have also been great aids in this direction. The American Pediatric Society has taken a prominent part in making attractive the study of the diseases of children. The full text of the address will appear in the next number of THE NEWS.

DR. AUGUSTUS CAILLÉ, of New York, read a paper entitled "Experiments as to the Value of Nascent Ozone in Certain Forms of Diseases of Children, with Demonstration of an Efficient Ozone-generator." The ozone-generator employed was first shown by Labbé and Oudin at the last meeting of the Congress for the Study of Tuberculosis. These authors reported thirty-eight cases of pulmonary tuberculosis treated with ozone, of which thirteen were reported as cured.

Dr. Caillé obtained a number of ozone-generators for experimental purposes, and placed them in the houses of trial-patients, in order to get the best possible results.

A number of cases of pulmonary tuberculosis in the first stage were investigated, as also were cases of chlorosis and pertussis. Particular notice was taken of the appetite, the strength, the weight, the vital capacity, and the percentage of oxyhemoglobin before and after treatment. The conclusions reached are as follows:

1. Inhalations of ozone from various apparatus have not been followed by noticeable ill-effects.

2. Daily inhalations of ozone increase the quantity of oxyhemoglobin in the blood from 1 to 4 per cent. in a short while, and this increase remains stationary for some time.

3. In typical cases of limited apex tuberculosis local improvement was not obtained by the ozone treatment.

4. In pertussis ozone has a very distinct curative effect as regards the duration and severity of the disease.

In chlorosis and in anemia, ozone inhalations are exceedingly valuable from a therapeutic standpoint, and give better and prompter results than any other form of medication.

Atmospheric disinfection is readily secured by means of Labbé and Oudin's apparatus, making this a valuable procedure in the treatment of diphtheria, scarlet fever, and other infectious diseases.

DR. CHAS. WASHINGTON EARLE, of Chicago, followed with a paper on "Manifestations of La Grippe in Children." He stated that there is accumulated testimony that very young children, ranging from a short time after birth to three months of age and older, are susceptible to influenza. The period of incubation is from a few hours to a week. In the West, the disease has been severe in its symptoms, with great irritability and mental depression, and in many cases with subnormal temperature. There is some similarity between influenza and diphtheria in their effects on the circulation and in their nervous manifestations. Loss of weight has also been a prominent symptom. It is important that cases should be early placed under treatment, and not be discharged too soon. The necessity of municipal control in affording means for preventing the spread of the disease was dwelt upon.

The subject was discussed by Drs. Rotch, Jacobi, and others, the consensus of opinion being that the type of disease described by Dr. Earle differed greatly in the severity of the symptoms from that seen in the East.

DR. ROTCH stated that the cases that he had seen in children were milder than those among adults. It seemed to him that the sympathetic system is profoundly affected.

DR. JACOBI was positive that the nervous symptoms of diphtheria and of influenza, respectively, are different in character and in cause.

DR. ADAMS expressed the view that climatic conditions had much to do with intensity of the symptoms.

DR. C. P. PUTNAM, of Boston, reported "An Epidemic of Alopecia Areata in an Asylum for Girls." Of sixty-nine of the children, sixty-three were attacked in the course of the year 1891. One girl was attacked in January, one in March, and just before the first of June sixty-one others were suddenly attacked. On the other hand, no matron or any of the older girls who served as assistant matrons had the disease, nor did any of the six girls who were sent to the country at the end of June have it. Careful and repeated examinations of the hairs had failed to show any microörganism. The appearance of the hairs was such as is ordinarily found in alopecia.

After the hair had been shingled, a corrosive sublimate solution was daily applied to the head of each child. The girls were divided into classes, and treated in different ways: one class with corrosive sublimate, two grains to the ounce; one with tincture of cantharides; one with thorough inunctions of sulphur ointment; one with cantharidal ointment; and one with turpentine.

From the middle of July the patients improved throughout the year, and at the end of the year comparatively little was to be seen of the disease, though at this date there were still a few bald patches, and on some of the larger spots the hair was growing sparsely.

No particular effect, however, was attributed to the various kinds of treatment. The progress of recovery was about the same in all of the different classes.

DR. BOWEN stated that the cases that he had seen showed no symptoms of ringworm, but were undoubtedly alopecia areata. Microscopic examination was negative.

DR. WHITE expressed the view that the cases differed in many respects from any he had yet seen; thus, for instance, in the angularity and in the number of the spots, as well as in the rapidity of development of the disease.

SECOND DAY—MAY 3D.

DR. A. JACOBI, of New York, submitted a brief report on "Hydrorrhachis and Hydrocephalus," and showed a pathologic specimen of spina bifida. The condition

was probably congenital. The case was treated by means of injections of Lugol's solution into the tumor, without much pain or inconvenience. The head was also aspirated, without bad symptoms, and fluid evacuated. Iodine was never found in the urine. The case finally died, the treatment not materially affecting its progress.

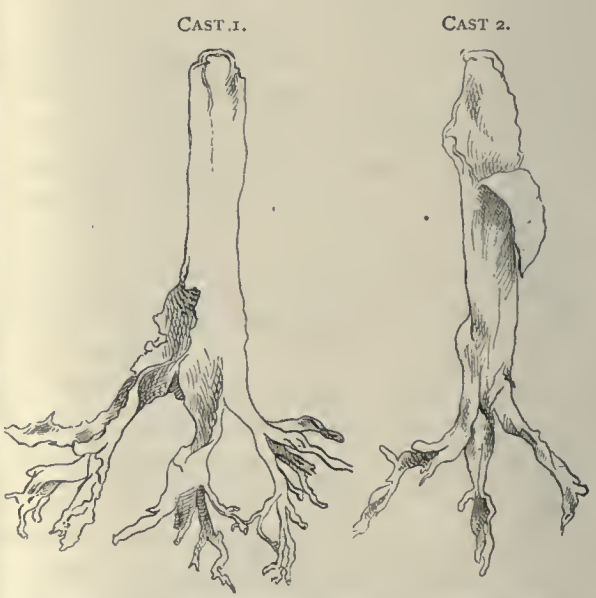
The specimen showed great atrophy, with club-feet and dislocation of both femurs, which was probably congenital.

In the discussion Dr. Jacobi added that a few cases have been benefited by treatment, but in the main the outlook is poor. It is none the less necessary, however, to do all that is possible for the relief of the cases.

DR. W. D. BOOKER, of Baltimore, read a paper entitled "Pseudo-diphtheritic Processes," in which he considered the similarities and the differences of diphtheria, scarlatina, and measles, the mode of invasion, and the difference between the tendencies of the respective affections. Specimens from different cultures of microörganisms were shown. The bacilli of diphtheria differ from those of pseudo-diphtheria in being more numerous.

DR. HENRY KOPLIK, of New York, read a paper entitled "Forms of Diphtheria which Simulate Simple Angina." He called attention to those forms of true diphtheria of the tonsils, pharynx, and larynx that, from a purely clinical inspection, it was at first glance impossible to positively differentiate from forms of angina of an innocent, though infectious, nature. He had directed his attention to the so-called doubtful cases, and had studied them both clinically and with the aid of bacterioscopic methods and animal inoculation. There are forms in which the diphtheria of the larynx or pharynx and tonsil is unaccompanied by the presence of any visible membrane. Such cases may run a mild course and infect others, who, in turn, may recover, but a third generation of infection may develop membrane in the throat, and end fatally. In a second form of diphtheria that simulates the innocent angina the membrane appears as a small speck on one or the other tonsil. In a third form of doubtful cases there is a single ulceration, sometimes covered with exudate, on one or the other tonsil. Some of these cases, taken to be simple ulcerated sore-throat, were shown by bacteriologic cultures and animal experiments to be true diphtheria, whereas other cases cited, almost identical in clinical features, were proven in the same manner to be non-diphtheritic. Still a fourth class of cases was constituted of those in which follicular appearances, such as are customary in follicular tonsillitis, were combined with minute patches of pseudo-membrane between the follicles on the surface of the tonsil. Some of these cases were shown to be diphtheritic. Dr. Koplik called attention to a class of cases that for many days would run the course of follicular amygdalitis, and suddenly develop symptoms of croupy voice and breathing, with specks of membrane on the palate, pharynx, and tonsil. Some of these cases had been observed daily without the detection of membrane, until the onset of the untoward symptoms noted. Some of the cases terminated fatally. Finally, a class of cases was described in which exudate appeared on the tonsils, and in which the pseudo-diphtheria bacillus of Hofmann, but not the true bacillus of Löffler, was found. The pseudo-bacillus was found, also, in forms of tonsillitis and laryngitis in which no membrane presented itself. These cases closely resembled the cases of diphtheria without visible membrane belonging to the first group of cases of true diphtheria with doubtful clinical appearances already considered. Thirty-four cases were examined in the clinical and experimental method indicated. No case was cited that had not been thus studied. Isolation of all clinically doubtful cases was advised as the best safeguard in general practice.

DR. F. HUBER, of New York, read a paper entitled "Two Tracheal and Bronchial Casts" (with plates). The two casts presented were coughed up by a girl, more than eight years of age, suffering from laryngeal, tracheal, and bronchial diphtheria. About a half-hour after intubation had been practised, a tube suitable for a child from five to seven years old being used, the patient suddenly became asphyxiated and dropped back apparently dead. Upon wrenching the jaws apart, the tube, displaced in the struggles, was readily removed with the finger. Proper remedies being applied, the patient rallied, and a large cast of the trachea and main bronchi was coughed up (Cast 1). On the following day, as the dyspnea recurred, tracheotomy was performed. A second cast of the trachea, bronchi, and ramifications was expelled through the tracheal canula a few seconds after its introduction (Cast 2). Death took place twenty-four



Cast No. 1.—Coughed out after removal of intubation-tube. (Reduced about one-half.)

Cast No. 2.—Coughed out through tracheal canula. (Reduced about one-half.)

hours later, in consequence of renewed formation of membrane. There had been no pyrexia until the fifth day, when the temperature rose to 101.5°.

The asphyxia that occurred shortly after the tube was inserted was not due to crowding down of the membrane by the tube. It was undoubtedly occasioned by the separation of the loosely attached membrane, in consequence of the irritation induced by the presence of the metal tube. It is the only instance in about two

hundred cases of intubation in which the accident occurred.

The facility with which the membrane was cast off is explained by the character of the tracheal and bronchial mucous membrane. If the epithelium (as in the trachea and bronchi) is cylindrical and numerous acinous glands secrete mucus, the membranes are loosely spread over the mucous membrane, from which they can be readily removed. The low temperature, so common in laryngeal and tracheal diphtheria, finds its explanation in the presence of large numbers of mucous glands, which do not permit absorption by the lymphatic vessels.

The specimens also show the rapidity with which membrane may be formed—from nine to ten hours sufficing to produce these large casts.

The unusual experience on the preceding day with intubation, the fact that the membrane was so readily thrown off, and in such large masses, induced a resort to secondary tracheotomy.

The two preceding papers were discussed by Drs. Caillé, Seibert, Fisher, Earle, and Jacobi. The consensus of opinion seemed to be that all cases should be isolated, and that doubtful cases should be viewed with suspicion.

DR. CAILLÉ expressed the view that treatment had not yet been influenced by the advances in bacterial knowledge.

DR. SEIBERT cautioned that even pseudo-membranous cases should not be looked upon as innocent.

DR. FISHER spoke of the necessity of making cultures in all cases as a means of accuracy in diagnosis before pronouncing upon a case.

DR. W. P. NORTHRUP, of New York, read a paper on "Typhoid Fever in Children Under Two Years." He insisted upon the difficulty of diagnosticating typhoid fever in children, and stated that among 2000 cases he had never seen a case of typhoid fever in young children (under two years). As to the lesions simulating typhoid fever, his experience was that swollen Peyer's patches and swollen mesenteric nodes in young children never meant typhoid fever. The object of the paper was to raise the question as to the frequency of the fever in young life and to warn against attributing to the lesions of the small intestine in young children the same interpretation that would apply in adults. The paper was intended to strengthen the view that typhoid fever in children under two years never occurs. The exceptions must be very rare. The cases used in illustration were worked out bacteriologically.

DR. CHARLES W. EARLE, of Chicago, presented a paper on "Typhoid Fever in Children." He maintained that very young children do have the disease, manifesting all of the symptoms as they are seen in adults, and sometimes dying from hemorrhage. He spoke of a case in a child three weeks old, in which bacilli were found. In twenty cases of his own that recovered, the youngest child was two years, the oldest seven and a half years of age. The characteristic symptoms were all present. Dr. Earle laid stress on the necessity of giving liquid food throughout the course of the disease. Antipyretics should not be used unless the temperature reaches 104°.

DR. W. S. CHRISTOPHER, of Chicago, read a paper on "Typhoid Fever in Infancy." He stated that in infants typhoid fever was in most cases milder than in adults. The febrile movement is slight; constipation is generally present; the spleen is enlarged, as determined by percussion; rose spots are also present. Dr. Christopher doubted, however, having knowledge of cases under two years of age.

In the discussion DR. NORTHRUP spoke of the extreme difficulty of detecting enlargement of the spleen by percussion, unless the organ extended below the margin of the ribs.

DR. HUBER spoke of the infrequency of typhoid fever in children younger than two years of age.

DR. SEIBERT expressed the belief that he had seen cases in children under two years of age, and spoke of irrigation of the lower bowel as a therapeutic procedure.

DR. ADAMS stated that in children the prominent symptoms met with in adults are usually wanting.

DR. ROTCH was of the opinion that the pathologic condition and methods of exclusion would aid in making a diagnosis.

DR. JACOBI related that he had seen several cases in children under two years of age. He thought that by exclusion and by the high temperature, the rose spots, and the diarrhea, a diagnosis might easily be arrived at.

DR. CHAS. W. TOWNSEND, of Boston, read a paper entitled "A Case of Sporadic Congenital Cretinism." The patient, an infant, twenty months of age, presented all the characteristic symptoms of cretinism. The skin of the face was thickened and edematous; the base of the nose was flattened; the tongue was large and protruding from the mouth. The extremities were relatively shortened, as shown by comparison with a normal infant. The thyroid gland was absent, as is the case in the majority of sporadic instances.

The child would frequently appear, for a period of from several minutes to an hour, as if dead, the respirations being feeble and almost suppressed, a feature commonly found in cases of the kind. The temperature in the rectum normally was 96.8°; the respiration was at all times not more rapid than from 12 to 17 in a minute. The mental condition was one of idiocy.

DR. HUBER stated that he had seen several cases of sporadic congenital cretinism in New York.

DR. B. K. RACHFORD, of Newport, Ky., read a paper entitled "The Anemia of Tuberculosis." He introduced his subject with the report of a case. A young girl, with a strong tuberculous family history, who had been constantly exposed to tuberculous contagion for years, presented herself with dyspnea, pain in the side, loss of appetite, sick stomach, great weakness and nervousness. There was no fever, no cough, and no physical evidences of either lymphatic or pulmonary tuberculosis. Two years previously, however, she had some "kernels" in her neck. The most striking symptom was extreme anemia. The blood was found to contain only 25 per cent. of the normal proportion of hemoglobin and 1,680,000 red corpuscles to the cubic millimeter. After three months of treatment with iron and arsenic, the patient was discharged, feeling better than she had for years. At this time the hemoglobin had a valuation of 90 per cent., and there were 4,000,000 red corpuscles to the cubic millimeter. Seven weeks later, although the patient said that she was well, an examina-

tion of the blood found only 65 per cent. of hemoglobin and 3,200,000 red corpuscles to the cubic millimeter. Two weeks of treatment again brought the hemoglobin to 90 per cent. Special attention was called to: 1st, the strong tuberculous family history; 2d, the constant exposure to the contagion; 3d, the "kernels" in the neck two years before the case came under observation; 4th, the absence of immediate evidence of glandular or pulmonary tuberculosis; 5th, the state of the blood; 6th, the improvement of the blood-state after treatment; 7th, the rapid diminution of the hemoglobin after the treatment was discontinued; 8th, the remarkable fact that the girl had escaped pulmonary tuberculosis for so long a time.

The cause of the anemia was by no means clear, and suggested an inquiry into the relationship of anemia and tuberculosis.

A table containing the family history and the blood-state of 166 convent girls was presented. In 58 cases, the family history was negative; in 30, the family history was good; and in 78 cases, there was a tuberculous family history. After excluding all the cases of apparent pulmonary and glandular tuberculosis, there still remained 69 cases with tuberculous family histories, with an average of 80¼ per cent. of hemoglobin, and 30 cases with non-tuberculous histories, with an average of 80 per cent. of hemoglobin. The table also showed that of the 37 anemic cases, 72 per cent. had tuberculous histories and only 7¾ per cent. had non-tuberculous histories. From these and other figures taken from the table presented, Dr. Rachford concludes that family tuberculosis is one of the great causes of anemia, even though there be no *apparent* active tuberculosis to account for the anemia. Eight cases of glandular tuberculosis presented in the table had an average of 57 per cent. of hemoglobin, and 10 cases of pulmonary tuberculosis had an average of 80 per cent. of hemoglobin. It is held that these figures show that it is tuberculous disease of the lymphatic system, rather than tuberculous disease of the lungs, that produces the most profound anemia. Dr. Rachford further concludes that the anemia in *apparently* non-tuberculous girls of tuberculous stock, is, when not readily explainable by other causes, very probably due to a deep-seated and hidden glandular tuberculosis; or, in other words, that *pronounced anemia, without apparent cause, is strongly suggestive of concealed tuberculosis.* In the light of these investigations he concludes that the case with which he opened his paper is one of deep-seated glandular tuberculosis.

THIRD DAY—MAY 4TH.

DR. A. SEIBERT, of New York, read a paper entitled "Syphilitic Broncho-stenosis in Children." The cases he reported were mostly among emigrants, particularly Russian Jews. The symptoms presented were dyspnea, cough, manifestations of laryngeal stenosis, together with signs indicative of bronchial stenosis. In one case intubation was performed, but without relief. The diagnosis was made by exclusion and by the rapid recovery under anti-syphilitic treatment.

DR. SAMUEL S. ADAMS, of Washington, reported "A Case of Death from Laryngismus Stridulus in Incipient Rhachitis." The case was that of a young infant, with convulsions and attacks of dyspnea, dying suddenly. In the absence of any determinable cause, death was ascribed to rhachitis.

In the discussion DR. JACOBI spoke of the exclusive use of milk as predisposing to the development of rhachitis. He expressed the view that, in the case reported, swallowing of the tongue might, perhaps, have been the cause of death, as death was stated to have occurred during swallowing, and symptoms of rhachitis in the case were not prominent.

DR. A. JACOBI, of New York, read "A Note on Peroxide of Hydrogen." He condemned the indiscriminate use of hydrogen dioxide, as in his experience the agent had shown marked irritating properties on the mucosa, and in diphtheritic cases aided in spreading the disease to neighboring parts of the buccal cavity. In each case its discontinuance was followed by improvement.

In the discussion it was elicited that other members had likewise had unfavorable experience with the remedy.

The discussion on "Chorea: its Relation to Rheumatism," was opened by DR. C. W. TOWNSEND, of Boston, who called attention to the fact that statistics as to the frequency of rheumatism in cases of chorea vary much, owing to the obscure nature of rheumatism in children. The questions to be considered are:

1. Does rheumatism occur with greater frequency among choreic than among non-choreic children?

2. Does rheumatism act simply as a debilitating disease in its relation to chorea, or is there an intimate relation between the two diseases?

3. Is the heart-murmur, often found in chorea, due to endocarditis, and is it liable to lead to serious heart-disease?

In answering these questions, Dr. Townsend considered all the cases of chorea in the Out-patient Department of the Boston Children's Hospital, 148 in number, from 1883 to 1890, a large number of which had been seen at the hospital, or visited at their homes after the original attack of chorea. He found that 21 per cent. of these had had rheumatism, and 30 per cent. a heart-murmur, one-half of the latter developing organic heart-disease. That there is an intimate relation between rheumatism and chorea seems evident from the large proportion of rheumatic cases among the latter. Among non-choreic children, only 5½ per cent. were rheumatic, or 12 per cent. including the cases of so-called "growing pains." Another reason for believing in the intimate relation of chorea and rheumatism lies in the fact that chorea is often followed or accompanied by rheumatism, as well as preceded by it, one sometimes giving place to the other.

The occurrence of endocarditis in chorea without rheumatism is considered a strong argument against the purely neurotic theory, and one that pointed to the infectious nature of chorea.

The conclusions reached were:

1. Fright, eye-strain, debility, and school-pressure—particularly the last, which often includes some of the others—are potent exciting causes of chorea.

2. Rheumatism, although absent from the history of at least half of the choreic cases, occurs with greater frequency among choreic than among non-choreic patients.

3. There is an intimate relation between chorea and rheumatism.

4. The heart-murmur, so frequently found in chorea, sometimes associated with rheumatism and sometimes not, is, in a considerable proportion of the cases, due to endocarditis, and leads to organic valvular disease.

Dr. M. A. Starr, of New York, was not present, but in a communication to the President bearing upon the occurrence of rheumatism and heart-disease in cases of chorea, he stated that the large majority (356) of the cases upon which his statements are based is taken from the records at the Vanderbilt Clinic, which are kept with much care. A small number are from his class at the New York Polyclinic, and the records in these cases are imperfect. The remainder are from private practice, in which, however, but few cases of chorea are seen, possibly because the higher classes are much less subject to the disease; possibly because it is usually treated by the family physician, and hence a consultant is not called.

Of 385 cases of chorea, 234 were general, equal 60 per cent.; 140 were unilateral, equal 36 per cent.; in 11 the extent is uncertain, equal 4 per cent.

A distinct history of rheumatism was obtained in 70 cases, equal 18 per cent.; in 281 cases rheumatism was denied; in 5 cases pains of a doubtful nature were admitted; in 29 cases no record was made of rheumatism.

Organic cardiac disease was found in 70 cases; functional murmurs were found in 56 cases; the heart was found to be normal in 212 cases; no statement was made regarding the heart in 47 cases.

In the twenty-nine cases in which no statement was made in the history regarding the occurrence of rheumatism, the probability is against its having been present—the omission of any record being equivalent to a denial on the part of the patient, as it has always been customary to inquire into the possibility of rheumatism. "Growing pains," or pains of an indefinite kind, are not included under "rheumatism." The cases in which rheumatism is noted were cases in which a distinct attack of acute articular rheumatism had occurred. The fact that the number having had rheumatism and the number having organic cardiac disease happens to coincide, is accidental. Many cases that had rheumatism or had been subject to rheumatism, were free from cardiac murmurs. Many that had cardiac murmurs denied having had rheumatism. The coincidence is none the less striking. In the majority of the patients with organic cardiac disease the diagnosis was confirmed by frequent observations subsequently to the recovery from chorea. In several cases the development of the heart-murmur had occurred during an interval between a first and second attack of chorea. About 20 per cent. of the cases have had relapses—some as many as five relapses while under observation—but it cannot be said that those that have had rheumatism are more liable to relapses than those that have not had it.

In 340 of the cases a record is made of the history of the parents as regards rheumatism and nervous diseases and pulmonary tuberculosis. In 58 cases one or both parents had suffered from rheumatism. In over 100 cases one or both parents were said to be "nervous."

Dr. F. M. Crandall, of New York, laid stress upon the fact that subacute rheumatism, as seen in the adult, may be very serious in the case of children. In 54 per cent. of cases of chorea, rheumatism was noted, while in 38 per cent. there was a rheumatic family history.

Dr. Adams considered neurasthenia an important factor in the development of chorea; more so than rheumatism, which holds an indirect relation to chorea.

Dr. Jacobi expressed the view that rheumatism is frequent in young children, and that cases should be more strictly investigated. He believed that rheumatism is related to chorea in some manner, endocarditis in chorea, in his opinion, being more frequently the result of unrecognized rheumatism.

Dr. T. M. Rotch, of Boston, read a paper entitled "The Value of Milk Laboratories for the Advancement of our Knowledge of Artificial Feeding." The paper was accompanied with diagrams. The different constituents of milk and their relative proportions in human milk and in cow's milk were considered. The methods employed in sterilizing milk were detailed. The importance of a pure milk in the first place was dwelt upon, as well as the necessity of the milk being adapted to the individual case.

Dr. L. Emmett Holt, of New York, read a paper entitled "A Simple Method for Clinical Examination of Breast Milk." He presented tubes, by means of which a proper estimate of the proportions of fat, sugar, and albuminoids can be made.

Dr. F. Huber, of New York, presented a communication entitled "Congenital Multilocular Sacro-coccygeal Cyst; Operation; Recovery." The case was that of a female child, of Russian Polish parentage, that at birth presented a multilocular cystic growth arising apparently from the posterior aspect of sacrum and coccyx. The pendulous mass was about four inches long and three inches wide, irregularly nodulated and rather ovoidal in shape; the skin covering it being thin, translucent, and of a dusky hue; on its surface ran large superficial veins. The base was somewhat constricted, though no distinct pedicle existed. Anus and rectum were normal.

On the nineteenth day, the first operation was performed. The skin was but loosely adherent to the growth, except where numerous fibrous bands separating the cysts were attached to the deeper layers of the integument and caused a retraction, giving rise to the irregular nodules visible on the surface.

The removal was accomplished by a process of dry dissection with the aid of blunt-curved scissors and the fingers, the fibrous bands only requiring to be divided. In spite of the numerous large vessels coursing over the surface, there was but little hemorrhage, until the deeper attachments to the coccyx were separated. In all, but three ligatures were employed. A small portion of the growth, situated to the right and running toward the rectum still remained. The child's general condition counter-indicated any further operative measures; it was, therefore, concluded to introduce a drainage-tube and suture the wound. The child rallied nicely. The middle third of the wound failed to unite primarily and was allowed to granulate from the bottom. When two months old, the remaining portion was removed. The skin over it was firm, thickened, slightly pigmented, somewhat hairy, and intimately adherent to the

growth. The mass contained a few cysts imbedded in a reddish-gray lipoma, but imperfectly encapsulated. An inch of the rectum was exposed in the process of enucleation.

In separating the adhesions to the coccyx (from which the growth evidently originated), an elongated cyst simulating a communication with the spinal canal presented itself. Only one vessel, the nutrient artery of the growth, entering at the tip of the coccyx, required a ligature.

The large mass first removed weighed seven ounces and was composed of a large number of cysts, separated from one another by dense fibrous tissue. The smaller, firm and solid, portion was composed of lipomatous tissue, in the midst of which were a few cysts; its weight was an ounce and a half. The larger cysts contained a fluid resembling that of a hydrocele; some of the smaller cysts, particularly those near the coccyx, contained a thick, yellowish, opaque fluid. The child rallied nicely from the second operation. A mild erysipelas and a rather severe intestinal catarrh delayed the favorable progress in the first week.

The formation of these growths has been attributed to included fetation, gemmation, or inclusion of a portion of the outer layer of the blastoderm at the time of the closure of the dorsal laminæ.

J. Bland Sutton classifies the congenital sacro-coccygeal tumors under four heads: 1. Sacral spina bifida. 2. Tumors originating in the post-anal gut. 3. Rectal dermoids, cystic tumors originating in the neurenteric canal. 4. Parasitic fetuses.

The multilocular cystic growths (the group most frequently met with in this situation, and particularly in females) may arise from the anterior or posterior surface of sacrum or coccyx, or both. Varying in size from an egg to a child's head, their subsequent growth may be quite rapid. As a rule, no pedicle exists, and exceptionally a communication with the spinal canal may occur. In some cases, the cystic character predominates in the growth; in other cases, fatty or fibrous tissue masses form the greater portion of the tumor, but few cysts being found. Cartilage, bone, and even intestine may be present.

The contents of the cysts resemble the fluid of a hydrocele; some of the smaller, particularly those attached to the coccyx, contain an opaque, yellowish material.

Ritschl, one of Kraske's assistants, made an exhaustive microscopic examination in one case. He describes three varieties of cysts, three kinds of glands, pieces of cartilage, round or horseshoe-shaped, smooth muscular fibers, and intestinal mucous membrane. Nerve-elements and striated muscular fibers were missing. The smallest round cysts were lined with pavement epithelium; the larger cysts contained a lining of epidermis, with hair in different stages of development. The majority presented a lining of ciliated cylindrical epithelium.

Solitary follicles, diffuse adenoid tissue, and a few acinous glands were discovered. The absence of voluntary muscular fibers and of nerve-elements leads Ritschl to the belief that the growth was not due to an intra-fetation. He is of the opinion that these tumors, from some unknown cause, are due to an arrest of the retrograde metamorphosis of fetal rudiments peculiar to this situation.

Many of the children thus affected are stillborn, others live a few days, and in those that survive, the mass increases, sometimes with great rapidity. Spontaneous cures have been reported from sloughing or ulceration; on the other hand a fatal termination may be caused by exhaustion or sepsis.

No partial measures should be employed in the treatment. When the question of operation arises, the probable existence of a communication with the spinal canal should not be forgotten.

Excision has given the best results and should be resorted to whenever possible.

The following officers were elected for the ensuing year:

President: A. D. Blackader, M.D., Montreal.

First Vice-President: J. M. Keating, M.D., Colorado Springs.

Second Vice-President: C. W. Earle, M.D., Chicago, Illinois.

Secretary: S. S. Adams, M.D., Washington, D. C.

Recorder: William P. Watson, M.D., Jersey City.

Treasurer: C. W. Townsend, M.D., Boston.

Member of Council: T. M. Rotch, M.D., Boston.

The Society adjourned subject to the call of the Secretary.

NEWS ITEMS.

Dr. J. M. Keating has resigned the editorship of the the *Climatologist.*

The Middleton-Goldsmith Lecture, before the New York Pathological Society, will be delivered by Dr. Francis P. Kinnicutt, on Wednesday evening, May 11th, at the Academy of Medicine. The subject of the lecture will be "New Outlooks in the Prophylaxis and Treatment of Tuberculosis."

The Association of American Medical Colleges will hold its third annual session in the Detroit College of Medicine, at 3 o'clock P.M., on Wednesday, June 8, 1892. Dr. N. S. Davis, President of the Association, will read a paper entitled, "To What Extent Should Clinical Instruction be Afforded the Student of Medicine in Regular Course?" Dr. V. C. Vaughan, of the University of Michigan, will read a paper entitled, "To What Extent Should Laboratory Instruction be Afforded the Student of Medicine in Regular Course?"

Correction.—In the article on "Gangrene of the Testicle," in THE MEDICAL NEWS of April 30, 1892, p. 490, the legend of the illustration should have read: Blood-smears from the gangrenous testicle. Cocci and bacilli. Stained by Gram's method. Beck's $\frac{1}{12}$ homo. im. Oc. 2. Camera-lucida drawing.

THE TECHNIQUE AND VALUE OF SPUTUM-EXAMINATION.[1]

BY VERANUS A. MOORE, B.S., M.D.,

OF THE DIVISION OF ANIMAL PATHOLOGY, BUREAU OF ANIMAL INDUSTRY, DEPARTMENT OF AGRICULTURE, WASHINGTON, D.C.; ASSISTANT DEMONSTRATOR OF PATHOLOGICAL HISTOLOGY, COLUMBIAN UNIVERSITY MEDICAL SCHOOL.

THE examination of sputum for tubercle-bacilli is undoubtedly the most serviceable of the known methods of differentiating pulmonary tuberculosis in its early stages from other less serious affections. The assistance to be derived from a thorough examination of the sputum in all doubtful or suspected cases is obvious when the fact is considered that tubercle-bacilli can be found in the sputum, in most cases, prior to the development of physical signs and symptoms that would warrant a positive diagnosis. While their discovery in more advanced cases eliminates any doubt that may be entertained as to the nature of the disease, the most practical value of such examinations is to be found when they are made in the cases of patients whose condition is still hopeful if placed at once upon proper treatment. The practicability of this comparatively simple means to assist in making a diagnosis at a time when it may be of inestimable value has prompted me to present, in a form very largely of a review, some of the more recent methods of preserving and examining sputum for tubercle-bacilli.

It is scarcely necessary at this time to dwell upon the well-known method of making cover-glass preparations directly from the crude sputum, and the staining of the same by Ehrlich's, Neelsen's, Gibbes's, or other methods that are usually given in detail in modern works on bacteriology and pathologic histology. This method is very satisfactory, and it seems to have no superior in the great majority of cases in which such examinations are usually made, but in a large number of more doubtful cases in which examination is especially desired for its diagnostic value, the advisability of relying upon negative results obtained from cover-glass preparations made directly from the crude sputum has been questioned, on account of the small number of tubercle-bacilli present in the beginning of the invasion and the unevenness of their distribution throughout the sputum. It is also a well-known fact that the method is primarily applicable only to a newly expectorated discharge, as the sputum, unless kept at a low temperature, very soon undergoes fermentation and putrefactive changes, which render it undesirable for examination, although the bacilli could still be detected if present in sufficient numbers.

In the beginning of the disease it is difficult and often impossible to detect the bacilli in a single specimen of sputum, especially if the usual method of making cover-glass preparations is employed. This necessitates the examination of a considerable number of preparations from each of several specimens taken at short intervals (the first expectorated on consecutive mornings is preferable), in order that the tubercle-bacilli, if present, may be detected or their absence assured. It must be borne in mind, however, that a large number of examinations with negative results does not positively affirm the absence of the disease.

In order to obviate the difficulties suggested and to increase the efficiency of sputum-examination, a few methods have been devised that, while not altogether new, appear not to have received the attention that their merits warrant. These, together with the well-known methods, appear to furnish means sufficient for every physician to secure the greatest possible assistance to be derived from such examinations. As the methods vary almost according to the necessity of the case, the process should be selected that is best adapted to afford the special information desired. The primary qualifications of the method to be chosen may be said to be those that will enable the examiner—

1. To discover the presence of tubercle-bacilli when they are present in very small numbers, as in the beginning of the invasion, as well as in larger numbers in more advanced stages of the disease.

2. To preserve the sputum without decomposition until examined, so that the examination need not be neglected on account of a necessary delay in its execution.

3. To determine, especially in the beginning of the disease, as approximately as possible the extent of the invasion, as indicated by the number of tubercle-bacilli present.

As already stated, cover-glass preparations, made directly from the sputum and stained according to some well-established method, give very satisfactory

[1] Read before the Washington Microscopical Society, Feb. 2, 1892.

results in nearly all of the more advanced cases. It is in the earlier stages of the disease that other methods are desired for preparing the sputum.

The staining process will not be given in connection with each of the methods of treating the sputum about to be mentioned, as any of the known methods can be employed, but subsequently a staining process will be described that is applicable to them all and which on account of its simplicity and efficiency I prefer to any of the other excellent methods with which I am familiar.

Biedert's method. The object of this method is *to find the tubercle-bacilli when they are present in the sputum in small numbers.* In 1886, Biedert (1) called attention to the fact that smearing the crude sputum on the cover-glass and staining the same does not give accurate results, so far as detecting the number of bacilli is concerned. This is due to the fact that clumps of sputum that usually contain a larger number of tubercle-bacilli than the more liquid portion are so deeply stained as to obliterate their presence. In order to reduce the sputum to a more homogeneous consistence and at the same time to concentrate into a small mass the bacilli in a large quantity of sputum, Biedert mixed the sputum with twice its volume of a 2 per cent. solution of caustic potash or soda (soda being preferred) and boiled the mixture until perfectly fluid, after which it was placed in a conical glass and allowed to stand until a sediment had formed. Upon decanting the supernatant liquid, tubercle-bacilli otherwise difficult or impossible to find were readily discovered in stained cover-glass preparations made from the sediment in the bottom of the vessel. In a recent article, (2) Biedert again dwells on the value of this method. Although the process requires considerable time, the advantage to be gained by concentrating the tubercle-bacilli in a large quantity of sputum into a small sediment is obvious. This is also a convenient method for preserving sputum for subsequent examinations, as the bacteria remain unchanged for a considerable time.

Among the various processes that have been proposed and which are based upon the principles set forth by Biedert, the following may be mentioned:

Kaatzer (3) employed from a 1 to 3 per cent. solution of caustic soda or potash, which dissolved the cells, mucus, etc., but preserved the elastic fibers and bacteria. Cover-glass preparations were made from the sediment. He also employed a dilute solution of acetic acid to clear the preparations.

Kühne (4) added an equal volume of a saturated aqueous solution of borax to the sputum in order to overcome its viscidity and to obtain a thin even layer on the cover-glass. This mixture remained good for several weeks. Putrefaction is prevented and the tubercle-bacilli continue to stain nicely. He also used for less viscid sputum a concentrated aqueous solution of ammonium carbonate. Kühne also dwells upon the importance of estimating the number of tubercle-bacilli present.

Mühlhäuser (5) does not advise the use of stronger solutions of caustic potash than 2 per cent. He differs from Biedert in taking a smaller quantity of the sputum and adding from six to eight times its volume of the potash solution.

Savelieff's method. The object of this process is *to preserve the sputum until examined.* In 1890, Savelieff (6) suggested a very convenient method for preserving the sputum and examining it bacteriologically at a more or less remote date after its expectoration. It consists in having the patient expectorate in a dish containing 95 per cent. alcohol, in which medium the discharge can remain for several months. As the sputum is hardened in the alcohol (through dehydration and coagulation), Savelieff liquefies the coagulated sputum with a solution of caustic potash prior to making the cover-glass preparations. The technique employed was to remove a small lump of the coagulum, place it upon a slide and add a few drops of caustic potash solution which reduced the coagulum in a very few minutes to a more or less pasty consistency from which the preparations were made. After drying, they were rinsed in water, to remove the potash, and stained. The film was fixed by passing the cover-glass three times through the flame of an alcohol lamp or Bunsen burner. Thus prepared, the preparation was stained by some familiar method.

Determination of the number of tubercle-bacilli in the sputum. While the determination of the number of tubercle-bacilli in the sputum is of special interest in studying the progress of the disease during a course of treatment, its practical value from a diagnostic standpoint is of much less importance. Although the extent of invasion in the early stages of the disease may be approximately determined by the number of bacilli found, providing the estimation can be made sufficiently accurate, the important factor is to determine whether or not the parasite is present. Furthermore, the methods for determining simply the relative number of tubercle-bacilli in the sputum are either so crude as to be unreliable or so complicated as to be impracticable for the regular physician. Of the methods proposed only two will be mentioned, and these very briefly:

Nuttall (7) has recently devised a method by which the total number of tubercle-bacilli in the sputum can be very accurately determined. It consists in collecting the sputum of twenty-four hours in a scrupulously clean dish, reducing it to a homogeneous consistence by treating it with a solution of potash; the accurate measurement of the total quantity and the making of cover-glass preparations

with a definite amount of the mixture that is determined by means of a specially prepared buret. For the details of this quite simple and excellent process the reader is referred to the original article. In one of the cases reported by Nuttall that was treated with Koch's lymph and from which he estimated the bacilli contained in the sputum on sixteen different days extending over the period from January 10th to March 1st he found the maximum number of tubercle-bacilli in the sputum of a single day to be 4,312,581,280; the minimum number was a little less than two billions.

In order to compare the number of tubercle-bacilli found in the sputum from day to day, Gaffky[8] made the following classification, although he considered it impossible to even approximately estimate the number of bacilli. It is important to note that from each case he examined but one preparation each day. According to the number of bacilli found on the cover-glass he placed it in one of ten divisions into which he divided them:

	No. of bacilli.
1. On the whole cover-glass . .	1–4
2. On several fields an average of .	1
3. On one field an average of . .	1
4. " " " . .	2–3
5. " " " . .	4–6
6. " " " . .	7–12
7. " " rather many.	
8. " " many.	
9. " " very many.	
10. " " an enormous number.	

It is evident that from a single preparation no trustworthy results could be obtained, on account of the variation in the thickness of the layer of sputum on the cover-glass and the unequal distribution of the tubercle-bacilli throughout the sputum. I have frequently found some preparations to contain few or no bacilli, while others made from the same specimen of sputum would contain a very large number.

My notes upon a considerable number of examinations show that frequently, when the total number of tubercle-bacilli found on several cover-glass preparations made from the same specimen of sputum averaged from 1 to 4, the symptoms were barely sufficient to cause a suspicion of the invasion. I have found on an average as many as from 100 to 200 and even more bacilli on every preparation examined from the same specimen of sputum from patients whose physicians supposed them to be suffering from uncomplicated bronchitis. Even a larger number have been found before the physical signs and symptoms were sufficiently developed to admit of a diagnosis of tuberculosis. While my observations have been quite limited and the cases from which the examinations were made may have been exceptional, yet the facts exist and furnish ample illustration of the importance of an early, careful, and thorough examination of the sputum.

Sectioning sputum. Savelieff's method suggested the possibility of hardening and sectioning the sputum. It seemed that by this process it would be possible to determine more accurately the relation of the tubercle-bacilli to the yellowish, more dense balls in the sputum than it is possible to do by means of cover-glass preparations. This method of treating sputum, however, I found had been anticipated by Schmidt [9] in the study of the histologic structure of sputum from patients suffering from asthma. While engaged upon this subject, Gabritschewsky's [10] article on the sectioning of sputum in the study of the so-called Buhl cells, alveolar epithelium and giant-cells and Aronson and Philip's [11] article on the sectioning of sputum and the exhibition of eosinophile cells in the same have appeared. Gabritschewsky found giant-cells in the sputum from three out of four patients suffering from pulmonary tuberculosis. The method, however, has not heretofore been employed in the examination of sputum for tubercle-bacilli.

The method used by Gabritschewsky is as follows: The more dense balls in the freshly expectorated sputum were placed in the hardening reagents for the usual period of time, after which they were imbedded in celloidin, sectioned, stained, and mounted the same as sections of ordinary tissue. The hardening fluids used were alcohol (beginning with the weak and increasing to the strong), Müller's fluid, Flemming's solution, chromic acid, picric acid, and corrosive sublimate solutions. The sections were stained with saffranin, alum-carmine, and hematoxylin-eosin. Alcohol for hardening and hematoxylin-eosin for staining were recommended. Schmidt imbedded the sputum in paraffin as well as in celloidin. Aronson and Philip hardened the sputum first in a corrosive sublimate solution.

In my experiments I have found that the sputum becomes so extremely brittle when hardened in alcohol that it can be handled without crumbling only with the utmost care. In order to eliminate this difficulty a paper cup, about one-third of an inch in diameter and from one-half to one inch long and perforated with pinholes, was made. This was filled with fresh sputum and placed immediately in alcohol (first 70, later 95 per cent.). After it had been in the alcohol for a few days it was imbedded in paraffin by the usual method, the paper being removed after the infiltration and just prior to the imbedding. By this means a cylinder of sputum about one-third of an inch in diameter was secured. Very thin sections were easily cut, fastened to cover-glasses and subsequently treated as sections of animal tissue. Owing to their fragility, care

must be exercised in fastening the sections to the cover-glass or slide, or portions will become detached during the staining process. Sections stained after Gabbet's process showed the tubercle-bacilli very beautifully lying singly or in clumps between the cell-elements. In the sections examined, the bacilli were usually found in aggregations of small clumps. Sputum hardened in alcohol showed the tubercle-bacilli much better than when Müller's fluid was used, although the latter exhibited the cell-elements more distinctly. The degenerated alveolar cells (Buhl's cells) are brought out more clearly when a little picric acid is added to the alcohol. This method, however, requires too much time to be practicable when the examination is made for its aid in diagnosis only, but for the study of the histologic elements of the sputum it offers many desirable features.

Gabbet's staining process. (12) I have found this method to be very convenient and quite satisfactory in staining the tubercle-bacilli both in cover-glass preparations and in sections of tuberculous tissue. The stain is practically the same as that used in Ziehl-Neelsen's method, but the acid is combined with the methylene-blue solution, thus decolorizing and counter-staining at the same time. I have compared this method with those usually recommended and find that it gives equally as good results as the more lengthy processes. The formulæ for the solutions and the technique in their application are as follows:

(1) The stain—

Fuchsin, . . .	1 gram.
Absolute alcohol, . .	10 cubic centimeters.
5 per cent. carbolic acid,	100 cubic centimeters.

(2) The decolorizer and counter-stain—

Methylene-blue, . .	2 grams.
25 per cent. sulphuric acid,	100 cubic centimeters.

For cover-glass preparations. After the smeared cover-glasses have dried in the air, they are passed film upward three times through a flame, after which the film is covered with the stain, which is allowed to act for about two minutes. The preparation is then rinsed in water and stained for one minute with the second solution, when it is again rinsed in water. It can be examined at once or allowed to dry, when it can be permanently mounted in balsam.

For sections, it is necessary to allow the reagents to act for a longer time. Better results may be obtained by heating the staining fluid until steam is given off. This is easily done by passing the preparation covered with the staining fluid several times through a flame, or heating the solution in a watch-glass upon which the cover floats film downward.

The tubercle-bacilli will appear upon a microscopic examination (an oil immersion lens is desirable) as slender, more or less curved, rod-shaped bodies of a deep-red color, while the surrounding tissue and other bacteria present are stained a more or less intense blue. There are occasionally small oval or round bodies found in preparations of sputum that retain the fuchsin stain and which beginners have frequently mistaken for tubercle-bacilli.

The solutions used in this method may be kept in stock for a long time (two to three years), but better results are obtained when moderately fresh solutions are employed. I would add that a 10 per cent. solution of sulphuric acid is quite as good and, I think, preferable to the stronger one recommended in the method.

CONCLUSIONS.

1. In all cases of bronchial or lung disturbances (not due to a known disease) that do not yield readily to treatment ordinarily successful, the sputum should be examined for tubercle-bacilli.

2. If tubercle-bacilli are not found in properly stained cover-glass preparations made directly from the sputum, Biedert's method or some modification of it should be employed to concentrate the bacilli in a large quantity of the sputum.

3. Several specimens of sputum should be thoroughly examined in all suspected cases before a negative conclusion is reached. In all such cases, an examination should be made from time to time, in order to detect the possible invasion of the bacilli at a later date.

4. In making the examination, fresh sputum should be employed, if possible. If a long delay is necessary, the sputum can be preserved in a 2 per cent. potash solution or in alcohol as previously described.

VACCINATION.

BY JOHN V. SHOEMAKER, A.M., M.D.,
OF PHILADELPHIA;
PROFESSOR OF MATERIA MEDICA, PHARMACOLOGY, THERAPEUTICS, AND CLINICAL MEDICINE, AND CLINICAL PROFESSOR OF DISEASES OF THE SKIN IN THE MEDICO-CHIRURGICAL COLLEGE OF PHILADELPHIA; PHYSICIAN TO THE MEDICO-CHIRURGICAL HOSPITAL, ETC.

THE discovery of the prophylactic value of vaccination is certainly one of the most interesting and important chapters in the history of medical science. A century has now elapsed since Jenner promulgated to the world the results of investigations in which he had long been engaged. During this period the practice has extended to every quarter of the globe, and its beneficent effects are beyond calculation. It is, indeed, a remarkable fact that in a disease so distinctly infectious as smallpox, the causative microörganism of which still eludes identification, a substitution-process should so long ago have been detected whereby a mild infection takes the place of a severe and loathsome disorder. The immunity conferred by vaccination, though not permanent, is, while it lasts, almost as complete as that due to smallpox itself, a fact well illustrated by the statistics of the Royal Military Asylum, at Chelsea, England. During forty-eight years, 5774 boys were admitted to the institution. Of this number 1950, on admission, bore evidences of having suffered from variola, while 3824 either had vaccination-scars or were at once re-vaccinated. Of those that had already had the disease 6.15 per thousand, and of those protected by vaccination 7.06 per thousand, subsequently contracted smallpox during their residence in the Asylum. In other words, neither the immunity due to an attack of vaccinia nor that due to an attack of variola is always permanent. Per contra, a single vaccination may have a lifelong effect.

It is noteworthy that, notwithstanding the high development to which bacteriologic and bacteriochemic studies have been carried, its most enlightened adherents have not as yet been able to devise prophylactic inoculation against scarlatina, typhoid fever, cerebro-spinal fever, croupous pneumonia, tuberculosis, or other dangerous infections.

The direct inoculation of variola, practised before the discovery of vaccination, was undoubtedly a step in advance, and decidedly reduced the gravity of the disease, including the disfigurement and blindness that it produced. Inoculation, however, was guilty of spreading the malady, while of inoculated cases 3 in 1000 terminated fatally. Death as a result of vaccination is almost unknown.

During the century, books and pamphlets have been issued from the press, and paper after paper has appeared in the journals upon the ever-interesting theme of vaccination. The progress of years seems to have no effect in diminishing these publications, yet, singular to relate, two eminent pathologists have recently arisen to deny the efficacy of Jenner's discovery. Critical disquisitions, however, must fall to the ground beside the simple statement of a few bare facts. Epidemics are not such veritable scourges now as they were during the eighteenth century. Scarred and blinded visages are now rarely seen upon the streets of the largest and most densely crowded cities; then, they were objects of every-day observation. In the Municipal Hospital of Philadelphia there were admitted, in 1871, 390 unvaccinated patients, of whom 254, *i. e.*, 65.5 per cent., died. During the same year, the total number of vaccinated cases was 799, and of these but 128, or only 16 per cent., perished. For upward of thirty years not a case of smallpox developed among the nurses of the London Smallpox Hospital, all the attendants of which are required to be re-vaccinated upon entrance. Re-vaccination is compulsory in the Prussian army. In forty years' time, less than 100 men in the entire organization fell victims to variola. Instances like these could be multiplied indefinitely, but to what use? I allude to the subject at all only to deplore the circumstance that men occupying high positions as teachers of science should lend countenance to the opposition of blind and ignorant zealots. Cavils concerning the nature and relationship of cow-pox, cattle-plague, grease, sheep-pox, etc., can never invalidate the cardinal truth, that successful vaccination protects against smallpox. It is, therefore, legitimate to conclude that true vaccinia and variola depend upon one and the same virus. This belief accords with what has been learned of late years concerning the nature of infectious disease, and with the results of experiments that are constantly being prosecuted with a view to producing immunity by the inoculation or injection of attenuated virus. It is along these lines that we may fairly hope for extension of prophylactic medicine in the future. The labors of Pasteur, Bouchard, Koch, Brieger, Behring and Kitasato, Klemperer, and others, lead us to believe that eventually practical measures will be devised, by the aid of which we shall have it in our power to counteract the development of some of the most fatal infectious disorders to which mankind is subject.

The employment of humanized virus is now nearly obsolete in this country. Some practitioners still cling to its use, and claim that the crust is both more reliable and more rapid in its effects than either the liquid or the dried animal lymph. In reply it may be urged that the action of the crust is also more severe. It is the testimony of Dr. Henry A. Martin, of Boston, that in two years after the introduction of the Beaugency virus into the United States, at

least 400,000 re-vaccinations had been performed by use of lymph derived from that source. Yet of this large number of operations in not a single case had death ensued from erysipelas or post-vaccine variola. Local and constitutional reaction is generally more severe when humanized virus is employed. One advantage may be imputed to the rapid action of the humanized lymph, and that is its ability to overtake and counteract variolous infection even when the latter has been at work for two or three days. We may, therefore, take advantage of this quality by employing humanized lymph after an individual has been exposed to contagion.

On the contrary, the crust stands convicted of two serious drawbacks: it is liable to occasion septicemia or to transmit syphilis. Vaccine syphilis is generally thought to be due to the blood adherent to the scab, but practically blood is always adherent to or mingled with the crust. It is also probable that this material is capable of propagating scrofulo-tuberculosis.

Bovine lymph is free from these serious objections, and certainly is efficient in preventing contagion. It may be less active, but, in view of its superior safety, the operation may, when necessary, be repeated until it succeeds. The animal matter has been used in two forms—as a liquid enclosed in capillary tubes, or dried upon quills or ivory points. In neither form does the lymph remain stable for any considerable period, though, when dried, its virtues are generally preserved for a longer period than when kept in the fluid state. This, perhaps, is not an exact statement. Undoubtedly, an exposed fluid more rapidly deteriorates than a thin layer of dried lymph, but, on the other hand, the former is put up in hermetically sealed glass tubes, so that while these remain intact it may be preserved for a long time from any cause that might bring about decomposition. The tube once opened, however, the lymph is liable to soon spoil, especially during the hot weather so common in the summer in this country.

Provided that it has undergone no change, fluid possesses some advantage over dried lymph as regards its efficiency of application. The latter needs to be dissolved in warm water while the surface is being abraded. Now, if it be rendered too fluid it may escape from the point. On the other hand, it may not be sufficiently dissolved. In the former case, much of it may be lost, and in the latter it may not readily be absorbed, and if by some accident too much blood flows from the abraded or scarified surface, the lymph may be prevented from entering the system. Either of these contingencies may be the cause of a failure that is unjustly blamed upon the quality of the matter. Pure fluid lymph is, consequently, preferable to the dried variety in that it is more easy of application. Either the scab or the incrustation upon points must be dissolved before it is used.

I have recently had placed in my hands for examination some specimens of a pure animal lymph, prepared by Dr. Pissin, State Councillor of Health, Berlin, at his Institute for Animal Vaccination, founded in 1865. So highly is it esteemed in the country of its origin, that it is exclusively employed as the material for vaccination and re-vaccination in the German army. It is obtained solely by calf-to-calf vaccination. The animals are subjected to rigid examination, and every possible source of impurity and contamination is carefully eliminated.

This lymph is put up in two forms. First, the *pure lymph*, which is a product of constant and unvarying activity, obtained directly from the calf. It should be used in a comparatively fresh condition, that is to say, within from four to six weeks after the date of preparation. This is a beautifully limpid fluid, almost as colorless as water, and is enclosed in hermetically sealed glass tubes. The *emulsified lymph* is prepared from the pure material by a special process. This preparation is a little thicker than the pure lymph, and is slightly turbid. It is equally effective, is far more stable, and retains its power for an indefinite period if the tubes are kept in a cool place. For many years, it is claimed, the results with Dr. Pissin's lymph have been 100 per cent. of successes in primary vaccinations, and from 80 to 90 per cent. in re-vaccinations. The materials are put up in tubes of different sizes, containing a sufficient quantity for five, ten, or twenty-five vaccinations.

The method in which it is used is as follows: The skin is cleansed with soap and water at the spot selected for the operation, and wiped quite dry. The extremities of the tube are then broken off, and a sufficient quantity of the lymph blown upon the skin, preferably upon four separate places. Then with a blunt lancet, or darning-needle, previously disinfected by passing through the flame of a spirit-lamp, the lymph is scratched in, care being taken not to abrade the epidermis, any effusion of blood being undesirable. The part should be allowed to dry before the clothing is readjusted, and should not be washed again for a week.

I have made use of both forms of this lymph, with entire success, and find that the claims made for it are borne out by my own experience. In every case the vaccine lesion was perfectly typical and unattended by any unusual local or constitutional phenomena. These tests exemplify not only the efficiency of the preparation, which is, of course, the chief point to be considered, but also incidentally the preservative influence of the sealed tubes—for the fine lymph, which is the least stable, did not

reach me until eight weeks after it had been received by the English agent, and it must have been at least a few days old when it first came into his possession. As regards fixity, therefore, it must be regarded as the equal if not the superior of lymph dried upon points. The emulsion that I employed was a fresher sample, being about two weeks old. Both varieties were entirely efficient.

The observations of several friends, to whom I distributed specimens of the lymph, corresponded precisely with my own, and we can therefore corroborate the favorable reports of foreign vaccinators regarding the preparation. I see but one objection to the article, and that simply concerns its mode of application, not its virtue. There is likely to be a waste of the fluid in the act of blowing, and some difficulty in effectually resealing the tubes.

THE INFLUENCE OF THE DOCTRINE OF CONTAGION UPON THE DEATH-RATE FROM TUBERCULOSIS IN THE CITY OF PHILADELPHIA.

BY LAWRENCE F. FLICK, M.D.,
OF PHILADELPHIA.

SINCE the discovery of the bacillus tuberculosis by Koch in 1882, the theory of the contagiousness of tuberculosis has more or less attracted the attention of the civilized world—not that the question involved was a new one, for it had been debated and re-debated both by the medical profession and by governments for centuries. It was, however, being approached in a new way, and it was the conclusiveness of the new evidence more than the question itself that arrested attention.

Thanks to the daily newspapers and the intelligence of the people, the practical measures that logically have grown out of the adoption of the theory are daily finding more advocates in the city of Philadelphia. During the first few years that followed immediately upon Koch's discovery, the medical profession stood out almost to a man against the theory. Now, however, the profession is nearly unanimous in its favor, and everywhere preventive measures are being introduced upon the suggestion of medical practitioners.

What has been the result of this propagation of the theory of the contagiousness of tuberculosis and of the partial and imperfect effort at prevention? If tuberculosis is contagious, we ought to have some result from even this little effort.

We have in the city of Philadelphia a record of mortality statistics from the year 1861 to the present time. In the accompanying table I give the population, the general mortality, the mortality-rate per 1000 living people, the mortality and the mortality-rate per 1000 living people from pulmonary tuberculosis for each year since 1861. It will be seen from this table that during the thirty years from 1861 to 1891 there was no real and continuous reduction in the mortality-rate from pulmonary tuberculosis until 1885,[1] and that since that time there has been a gradual and continuous reduction. The importance of this reduction will be emphasized, too, when we bear in mind that during the last three years of this time we have had an epidemic of influenza, which materially increased the mortality from pulmonary tuberculosis.

MORTALITY OF PHILADELPHIA.

Year.	Population.	Deaths.	Deaths to 1000 living.	Deaths from pulmonary tuberculosis.	Deaths from pulmonary tuberculosis to 1000 living
1861	576,408	13,540	23.49	1,817	3.152
1862	587,287	13,864	23.60	1,949	3.318
1863	598,166	14,220	23.73	1,955	3.268
1864	608,045	15,875	26.10	2,089	3.435
1865	618,924	15,633	25.25	2,026	3.370
1866	630,803	15,362	22.80	1,944	3.081
1867	640,682	12,660	19.76	1,947	3.038
1868	651,561	13,391	20.39	1,995	3.061
1869	662,440	13,428	20.27	1,975	2.981
1870	674,022	15,317	22.72	2,308	3.424
1871	700,000	15,485	22.12	2,337	3.195
1872	725,000	18,987	21.19	2,330	3 213
1873	750,000	15,224	26.29	2,291	3.054
1874	775,000	15,238	19.66	2,304	3.118
1875	800,000	17,805	22.25	2,359	2.948
1876	825,594	18,892	22.88	2,676	3.241
1877	850,856	16,004	18.81	2,349	2.760
1878	876,118	15,743	17.97	2,491	2.843
1879	901,380	15,473	17.17	2,481	2.741
1880	846,980	17,711	20.91	2,692	3.178
1881	868,000	19,515	22.48	2,768	3.188
1882	886,539	20,059	22.62	2,809	3.168
1883	907,041	20,076	22.13	2,798	3.084
1884	927,995	19,999	21.55	2,801	3.018
1885	949,432	21,392	22.53	2,821	2.971
1886	971,363	20,005	20.59	2,834	2.927
1887	993,801	21,719	21.85	2,800	2.817
1888	1,016,758	20,372	20.04	2,695	2.650
1889	1,040,245	20,536	19.74	2,532	2.434
1890	1,046,964	21,732	20.76	2,764	2.640
1891	1,069,264	23,367	21.85	2,624	2.454

If we divide the thirty years into decades, and carefully study the population and the mortality-rate from pulmonary tuberculosis side by side, we will be able to note the following interesting facts. The mortality-rate from pulmonary tuberculosis rises and falls at intervals during each decade, but much more markedly so during the first and second than during the third. This phenomenon is partly due to mistakes in the estimates in population, as will be seen by a scrutiny of the population-column, and is partly incidental to tuberculosis, as shown in my paper on the "Contagiousness of Phthisis."[2]

During the first decade the estimates of population are nearly correct, and we have the natural rise and fall in the mortality-rate well illustrated. During

[1] The slight reduction between 1881 and 1885 is probably mainly due to the natural rise and fall in the mortality of the disease.

[2] Transactions of the Medical Society of the State of Pennsylvania, 1888.

the second decade the estimates in population are very much too high, and as each year has not only the over-estimate of population but also the accumulated excess of the preceding years, the mortality-rate becomes progressively vitiated during this decade. It will be seen, however, that the general appearance of the mortality-rate from tuberculosis during this decade is about the same as that of the preceding, registering the same rises and falls. Were the estimated population correct, it would show almost identically the same figures, as will be seen by referring to the column giving the gross number of deaths from pulmonary tuberculosis. During the third decade the estimates in population are likewise a trifle too high, which is to be borne in mind in studying the mortality-rate; but even allowing for this, it will be seen that the rate for the decade differs materially from that of the preceding two. There is but a single rise and there is a gradual and permanent reduction.

In the first and second decades the variation in the mortality-rate is really a rise above the starting-point, and a drop back to it, whilst in the third decade there is a gradual and continuous decline. In 1861, the mortality rate was 3.152; in 1871 it was 3.195; in 1881, it was 3.188, whilst in 1891 it was 2.454. During the decade between 1861 and 1871, the rate dropped below 3 per 1000 only once, namely in 1869, when it was 2.981. This reduction was in part due to a slightly exaggerated population, in part to the generally low mortality-rate from all diseases for the year, and in part no doubt to the natural variation in the mortality from the disease. During the decade between 1871 and 1881 the rate dropped below 3 per 1000—in 1875, when it was 2.948; in 1877, when it was 2.760; in 1878, when it was 2.843; and in 1879, when it was 2.741. During all these years, the apparently lower rate was really due to an over-estimate of the population, as will be shown by a careful study of the population-column and the column giving the gross number of deaths from pulmonary tuberculosis. The census returns for 1880 make the population nearly 60,000 below the estimated population for 1879, and the gross returns from pulmonary tuberculosis during the decade show a constant increase from 1871 to 1881. Were the mortality-rates for the years during this decade computed on the basis of the correct population, it would probably at no time go below 3 per 1000. During the decade between 1881 and 1891, there is a gradual diminution from 3.188 in 1881 to 2.454 in 1891. It will be seen that there is a reduction every year except during the year 1890, when there is a slight increase. The increase for this year is partly due to over-estimated population during the preceding years, and partly due to influenza.

If we study the mortality-rates from pulmonary tuberculosis side by side with the number of deaths from the disease and the population for the thirty years as a whole, we shall see that during the entire period there has been no material decrease in the death-rate from pulmonary tuberculosis until the last few years, and that the decrease becomes more rapid as we approach the present year. The actual decrease from 1881 to 1891 is 0.734 per 1000 of living people, which with our present population means a saving of 784 lives a year.

To what can this most fortunate reduction in our mortality from pulmonary tuberculosis be ascribed? Upon the theory that the disease is contagious, it is easily understood, and upon no other can it be explained. Since the question of the contagiousness of tuberculosis has been discussed in the newspapers, most people, even though they may not have believed in the contagiousness, have adopted preventive measures. The majority of physicians have, moreover, during recent years strongly urged preventive measures when attending persons suffering from the disease. The effect of these efforts is showing itself in a reduced mortality-rate. That so excellent a result should follow such trifling efforts is in accordance with what we know about the preventability of tuberculosis. Owing to the fact that the contagion is necessarily confined to the pus given off from a tuberculous ulcer or broken-down nodule, tuberculosis is of all diseases the most easily preventable. All that is necessary is to confine and destroy this pus, and the most intimate relations between sick and well can be safely maintained.

736 PINE STREET

THREE FATAL CASES OF CEREBRO-SPINAL MENINGITIS, WITH AUTOPSIES.

BY HERMAN B. ALLYN, M.D.,
INSTRUCTOR IN PHYSICAL DIAGNOSIS IN THE UNIVERSITY OF PENNSYLVANIA.

I DESIRE to report these three cases because they occurred immediately following a widespread epidemic of influenza, in which cerebro-spinal symptoms were among the most characteristic features of the disease. At such a time, the possibility of mistaking the graver for the milder affection is much more likely to occur, especially when one is not on his guard. These cases may, therefore, serve a useful purpose in the way of warning.

The first patient was a man, forty years old, married, and engaged in running coal-cars at Greenwich Point. After working for twenty-nine consecutive days, he awoke, on the morning of February 1st, with a headache, which became worse, and after breakfast he was suddenly seized with severe pain in his right ankle. He went to Greenwich Point to get excused for the day, and on his way home—a long walk being necessary—he became so weak in

his legs and feet that he fell down. He lay on the ground for three hours, unable to rise, and vomiting profusely, and was possibly unconscious part of the time. A passing driver roused him, and, between driving and walking, he managed at last to get home in an extremely prostrated condition. He complained of pains in his knees, ankles, back, and head—pain in the latter being most intense. He was delirious during Monday night; and between three and four o'clock the next morning became unconscious, with rigid limbs and clenched teeth. This comatose condition lasted several hours and then gave place to delirium, from which the patient was never afterward wholly free.

In addition to the local pains he had general hyperesthesia. For a few nights the delirium was maniacal, the patient fighting with his attendants and jumping out of bed. Insomnia was persistent.

On Friday, an herpetic eruption appeared on the lower lip, and on the right wrist there were some forty or fifty papules, which subsequently became pustules, and then dried up. The wrist was stiff, tender, and somewhat swollen. The fever was moderate, the pulse under 90, and the respiration about 20. There was marked tenderness along the spine, especially in the lumbar region and at the nape of the neck. There was never any opisthotonos, retraction of the head, or convulsions. The lungs and heart were free from disease. Constipation was obstinate. The urine contained the merest trace of albumin and no casts. The conjunctivæ were injected.

Gradually a typical ataxic typhoid condition developed, the temperature rose, the pulse and respiration became more frequent, delirium was persistent, and it was increasingly difficult to feed him.

On February 18, he was completely comatose, with very high fever and moist skin; pulse, 160; respiration, 64. He died after an illness of eighteen days.

The autopsy was held the same evening by Dr. Jameson, assisted by Dr. W. S. Carter and myself. The heart, lungs, liver, spleen, and intestines presented nothing abnormal. There was only one kidney, and that was the seat of acute and chronic nephritis.

The brain itself appeared normal, except for some softening. The lymph-spaces of the pia were distended, and the arachnoid and pia injected. At the base, particularly surrounding the medulla, the arachnoid and pia were inflamed, the pia being adherent to the medulla, pons, and cerebellum and to the upper portion of the cord. A small quantity of lymph was found, particularly around the circle of Willis and the anterior perforated space. The blood was fluid. No cultures were attempted.

The second patient was a healthy man, twenty-eight years old, who was called in to care for the first patient at night. After several days of this watching, on February 5th, he complained at dinner of having pain in his back. He then went out into the back yard and while there fainted. He regained consciousness, and went upstairs to bed, complaining of being cold and of intense headache, backache, and pains "all over." The pain in the head was agonizing. Explosive vomiting occurred twice. Delirium was sportive and jocular in type. He sang a comic song, got out of bed to obtain a glass of cold water, poured it over his head, and, after making an intelligent reply to a question, was supposed to be sleeping quietly. He was found dead at twenty minutes past four, his illness having lasted about three days.

In a very short time after death, the back, from the shoulders to the buttocks, was purple from effused blood. Rigor mortis set in very early.

The autopsy was held on the following day by Dr. T. J. Ellinger, assisted by myself. Only the brain and cord were examined.

The dura mater was adherent, though not tightly, to the skull. The pia was everywhere adherent to the brain. From about the anterior temporal convolutions posteriorly the lymph-spaces in the pia were much distended with yellow lymph. The injection of the pia and arachnoid gave the brain a bright-red appearance, contrasting strongly with the empty blue veins. The brain itself was anemic. The blood wherever found was black and fluid. The inflammatory adhesions were especially well marked at the base, over the medulla and pons.

The spinal canal was full of black, fluid blood; the upper portion of the cord was much softened. The spinal dura had to be stripped from the walls of the canal. There were some flakes of lymph upon the membranes. Gelatin test-tubes were inoculated with the lymph.

The third patient was a sister of the first patient. She was forty-eight years old. There had been, as far as could be ascertained, no communication between sister and brother. She went to bed on the night of March 6th apparently perfectly well, except that she complained slightly of pains in her joints. She had eaten very heartily of turkey. During the night she was seized with a chill, with vomiting and purging, but no one knew of her illness until about five o'clock the next morning. I saw her first about 4 P.M., March 7th. Vomiting and purging had ceased; she was extremely weak, with cold skin and feeble, frequent pulse. The conjunctivæ were injected and the pupils contracted. The patient had no pain, except in the forehead. She continued conscious and quiet until twelve o'clock midnight, when she became comatose; pulse, 160; respiration, 40. She died in the same condition at 2.45 A.M., her illness having lasted about twenty-four hours.

The autopsy was made by the Coroner's physician the same evening. All the organs were soft and friable, with acute parenchymatous degeneration. The stomach and intestines showed marked inflammation. The mucous membrane was inflamed and softened and appeared rough, as though stripped of its epithelium. The dura was moderately adherent to the skull. The pia and arachnoid were thickened, and the outer surface had a gelatinous appearance, that next to the brain being much injected, but not adherent to the brain over the cortex. The lymph-spaces were full, the veins empty. There was an unusual amount of fluid in the brain, and the brain itself was much softened. At the base,

the same lesions were found as in the other cases, but were not so marked.

It is remarkable that these three cases occurred practically in one family, and that all of the patients were adults. The first case progressed gradually to a fatal issue, lasting eighteen days. The second was fulminating, lasting only three days. The third presented all the symptoms of acute toxic gastro-enteritis, with collapse and death. It would not have been regarded as a case of meningitis but for the findings at the autopsy.

The diagnosis from influenza, with which cerebro-spinal meningitis was most likely to be confounded, can be made in most cases by noting the occurrence, at the onset of the disease, of chill, vomiting, and faintness, accompanied or followed immediately by headache and backache, the headache being more frequently occipital than is the headache of influenza. Subsequently there are hyperesthesia of the skin, stiffness and tenderness of the muscles of the neck, injected conjunctivæ, delirium, and frequently convulsions. Eruptions, most frequently herpetic or petechial, are absent as often present. The occurrence of other cases of the same kind stamps the disease as epidemic cerebro-spinal meningitis. Coma sometimes alternates with delirium and usually succeeds it in lingering fatal cases.

The ages of the patients probably account for the absence of convulsions.

ORIGINAL ADDRESS.

REMARKS ON SPECIALISM.

Made at the fourth annual meeting of the American Pediatric Society, Boston, May 2, 1892.

BY WILLIAM OSLER, M.D.,
PROFESSOR OF MEDICINE IN THE JOHNS HOPKINS UNIVERSITY, BALTIMORE.

GENTLEMEN: First let me express my gratitude for your kindness in conferring upon me the honor of your presidency—an honor enhanced by the standing and character of the men who have previously occupied this chair. To have selected as your presiding officer one whose work has lain in the wide field of general medicine, is an indication that you duly appreciate the relation of the special subject in which we are now interested, and to which this Society is devoted. The diseases incident to infancy and childhood are so varied, covering every department of internal medicine, as well as of surgery, that the broad distinctions emphasized by the names physician and surgeon suffice to characterize us, and happily we have not yet been stamped with a distinctive appellation, under which so many of our colleagues in other lines labor. In the extraordinary development of modern medicine, some limitation in work is inevitable, and although as practitioners and teachers we are all, to some degree, necessarily interested in the diseases of children, there are among us those who find in such diseases their chief occupation, and our Society is but an organized expression of a natural desire to unite for the purposes of study.

On an occasion of this kind it seems best to me not to discuss any particular subject in children's diseases, as such discussion is almost certain to come up subsequently in our meetings, but to deal with some problem of general interest, with bearings, however, upon our organization. In comparison with the older countries of Europe, specialism may truly be said to be the most distinctive feature in the medical profession of America; and it may not be inappropriate to consider here a few of its advantages and disadvantages.

"That which has been is that which shall be." Medicine may be said to have begun with specialists. The Ebers Papyrus is largely taken up with the consideration of local diseases; and centuries later we find in Greece certain individuals treating special ailments, and Aristophanes satirizes a "rectum specialist" in a way not unlike our comic journals would "poke fun" at an oculist or an aurist. The tail of our emblematic snake has returned into his mouth: at no age has specialism been so rife. To follow its gradual development during the present century would take more time than is at my disposal, and would not be a profitable task. The rapid increase of knowledge has made concentration in work a necessity; specialism is here, and here to stay.

The advantages to the profession that have followed this differentiation have nowhere been more striking than in this country, and the earnest workers in ophthalmology, gynecology, dermatology, and other branches have contributed largely to inculcate the idea of *thoroughness*, the necessity for which is likely to be lost sight of in the hurry and bustle incident to the growth of a nation. Better work is done all along the line; a shallow diffuseness has given place to the clearness and definiteness that comes from accurate study in a limited field. The day has gone by for Admirable Crichtons, and although we have in our ranks a few notable illustrations of men that have become distinguished authorities in eye and skin diseases, and upon syphilis, without sacrificing their interests in general surgery, such are necessarily rare, and unfortunately, from the very circumstances of the case likely to become more uncommon. Then, how comforting to the general practitioner is the wise counsel of the specialist. We take him a case that has puzzled and annoyed us, the diagnosis of which is uncertain, and we consult in vain the unwritten records of our experience and the printed records of our books. He labels it in a few minutes as a coleopterist would a beetle, and we feel grateful for the accuracy of his information and happy in the possession of the label; and if sometimes, standing like Aaron between life and death, he illumines too brightly the darkness of our ignorance, are we not as often beholden to him for gentle dealing?

It is almost unnecessary to remark that the public in which we live and move has not been slow to recognize the advantage of a division of labor in the field of medicine. The desire for expert knowledge is, however, now so general that there is a grave danger lest the family physician should become, in some places, a relic of the past. It must indeed be a comfort to thousands

to feel that in the serious emergencies of life expert skill is so freely available. Perhaps, as specialists, no class in our profession has been more roundly abused for meddlesome work than the gynecologists, and yet what shall not be forgiven to the men that, as a direct outcome of the very operative details that have received the bitterest criticism, have learned to recognize tubal gestation, and are to-day saving lives that otherwise would inevitably have been lost? I have known Formad to show in one year, at the Philadelphia Pathological Society, ten or twelve examples of ruptured tubal pregnancy obtained in medico-legal work (sudden death) in that city. The benefits the public reaps from specialism may be gathered from the fact that in a not much longer period of time I have seen seven specimens of tubal gestation, not removed by the pathologist, but by the gynecologist, with the saving of five lives. The conservatism that branded ovariotomists as butchers and belly-rippers is not yet dead among us, and I say it frankly, to our shame, that it has not always been professional encouragement that has supported daring advances on special lines. Humanity owes a great debt of gratitude to the devoted men that have striven during the past half-century for exactness in knowledge and for the practical application in all departments, a debt too great to pay, too great, one sometimes feels, even to acknowledge.

Specialism is not, however, without disadvantages. A radical error at the outset is the failure to recognize that the results of specialized observation are, at best, only partial truths that require to be correlated with facts obtained by wider study. The various organs, the diseases of which are subdivided for treatment, are not isolated, but complex parts of a complex whole, and every day's experience brings home the truth of the saying: "When one member suffers, all the members suffer with it." Plato must have discussed this very question with his bright friends in the profession—Eryximachus, perhaps—or he could never have put the following words into the mouth of Socrates: "I dare say that you may have heard eminent physicians say to a patient who comes to them with bad eyes, that they cannot cure his eyes by themselves, but that if his eyes are to be cured, his head must be treated; and then again they say that to think of curing the head alone, and not the rest of the body also, is the height of folly. And arguing in this way they apply their methods to the whole body, and try to treat and heal the whole and the part together. Did you ever observe that this is what they say?"[1] A paragraph that embodies the law and the gospel for specialists.

A serious danger is the attempt to manufacture rapidly a highly complex structure from ill-seasoned material. The more speedy success that often comes from the cultivation of a specialty is a strong incentive to young men to adopt early a particular line of work. How infrequently are we consulted by sucklings in our ranks as to the most likely branch in which to succeed, or a student, with the brazen assurance that only ignorance can give, announces that he intends to be a gynecologist or an oculist. No more dangerous members of our profession exist than those born in it, so to speak, as specialists. Without any broad foundation in physiology or pathology, and ignorant of the great processes of disease, no amount of technical skill can hide from the keen eyes of colleagues defects that too often require the arts of the charlatan to hide from the public.

In the cultivation of a specialty as an *art* there is a tendency to develop a narrow and pedantic spirit; and the man that, year in and year out, examines eyes, palpates ovaries, or tunnels urethræ, without regard to the wider influence upon which his art rests, is likely, insensibly perhaps, but none the less surely, to acquire the attitude of mind of the old Scotch shoemaker, who, in response to the Dominie's suggestions about the weightier matters of life, asked "D'ye ken leather?" There is not a single department of which the study does not carry with it the correction of this most lamentable tendency. Problems in physiology and pathology touch at every point the commonest affections, and exercised in these, if only in the early years of professional life, the man is chastened, so to speak, and can never, even in the daily round of a most exacting practice, degenerate into a money-making machine. And let the younger of my hearers lay this to heart: Scan the lives of say twenty of the men most prominent in special lines of medicine and surgery to-day in this country, and you will find, with scarcely an exception, the early years devoted to anatomic, physiologic, or pathologic studies. They rose high because the foundations were deep. The most distinguished oculists have been trained in physiology and pathology, and some, like Sir William Bowman, have had reputations so preëminent in several departments that the identity of the physiologist has been lost in the ophthalmologist.

The work of the specialist encroaches more and more upon that of the general practitioner, and this condition, though in many ways to be regretted, is not likely to be changed. I have known the head of a household pay in the course of a year for the professional services of six physicians, a gynecologist, an oculist, a laryngologist, a dermatologist, and a surgeon. What remained after this partition of the great practitioner came in sixth and looked after the children. It is interesting to note that to this one pertains, to a large extent, the functions of the old family physician, and further advice is usually sought through him, or at his suggestion. In the evolution of the specialist the "children's doctor" is the last to appear, not because of any extreme differentiation, but he represents a vestigial remnant of what was formerly in cities the general practitioner. May I not say that there are members of our Society whose interest in their work is largely due to this new feature in domestic life? In the division of the household among our brethren, the children alone remain, and fortunately their ailments are too diversified to allow of much specialization.

After all, though specialism is rife and has so carved the body of physic that Hippocrates would scarcely recognize it, and though its sounds go out loudly and echo in the journal and society reports, nevertheless I would boldly make claim for a wider diffusion of its benefits. Of dwellers in cities arrogance is a special trait, and we discuss problems in a surely-we-are-the-people style, forgetting that outside lie the greater

[1] Charmides: Jowett's translation.

millions equally precious to Æsculapius, and under the care of men that cannot specialize, who must be able to set fractures, perform version, treat iritis as well as fevers, ear-ache as well as itch. What of the benefits of specialism to this larger class from the ranks of which the cities are replenished and the health of which is so essential to the nation? The out-door departments of the hospital and consulting rooms of the city physicians tell of the necessity of special knowledge to these people, particularly in emergencies and in the grave and more unusual forms of disease; but those that can thus avail themselves form but a fraction of the number that require technical skill for the purpose of diagnosis or treatment. Very little additional knowledge enables the general practitioner to grapple with a large proportion of the cases that in cities come under the care of the specialist. The question resolves itself into one of education. It is impossible in three collegiate sessions to bring men beyond the superficial routine, but in a more prolonged period of study—as I know from experience—the student can be taught practically in the wards and in the dispensary enough of the technique of the specialist to give at least a foundation upon which to work. He should leave the schools knowing the practical application of the microscope, the ophthalmoscope, and the laryngoscope, and in these and other lines he should have proceeded to the stage in which he recognizes the limitations of his knowledge. Such a man in general practice should know a "choked disc" when he sees it; the examination for tube-casts should be a familiar everyday task; and he should be able to tell whether a vocal band is paralyzed or not. A serious obstacle to this happy consummation—which can be reached in a well-ordered system of education—is the absence, in the early years of practice, of material upon which to freshen the memory and to "keep the hand in"; but the man that once, as a student, has reached a certain point always retains some measure of the old facility. The post-graduate schools have done much to enable men to revive and to acquire technical skill, and have been of great service in generalizing special knowledge. In the practice of a good all-round man, the number of cases demanding the help of a specialist is, after all, not very great. The ordinary run of nervous disorders should be recognized; adenoid vegetations should be treated with the skill of the laryngologist; he should know enough not to tinker with a case of glaucoma; and though he may not differentiate a pus tube from tubal pregnancy, he should in this, as in other details, have learned to know his limits and be ready to seek advice.

With the revival and extension of education, the benefits of specialism will become more widely diffused, and to this end the efforts of colleges and hospitals should be directed.

The organization of societies for the study of particular diseases has of late been a very noticeable feature in the professional life of this country. Since the foundation of the Ophthalmological Society more than a dozen associations have been formed, and their union in a triennial congress has proved a remarkable success. These societies stimulate work, promote good-fellowship, and materially aid in maintaining the standard of professional scholarship. They are, as a rule, exclusive bodies, limited in membership, and demanding for admission evidence of special fitness. This point is sometimes urged against them, but the members exercise no arbitrary privilege in asking of candidates familiarity with the subject and evidence of ability to contribute to the general store of knowledge. In some of the specialties these societies have been most useful in disciplining men that have traduced, not the written code but the unwritten traditions of our craft, acting as if they were venders of wares to be hawked in the market-places.

Our own Society may be regarded as the outcome of a notable revival, during the past few years, of interest in the study of the diseases of children. The existence of a special journal devoted to pediatrics and the successful issue of a large cyclopedia of the *Diseases of Children*, testify to the appreciation on the part of the profession of the necessity for more accurate study of this branch. The Society offers to men who are working in, and teaching pediatrics, an opportunity of knowing each other, of discussing subjects of common interest, and through the medium of their publications making general the more special details of value in practice.

The program before you indicates clearly that we are all workers in general medicine; and may the characters of the papers and the discussions be the best justification of the existence of an organization devoted to the study of a particular section of that field.

ORIGINAL LECTURE.

NON-FATAL LACERATION OF THE SPINAL CORD —INTRA-DURAL HEMORRHAGE, WITH UNDISCOVERED COMPRESSION.

Delivered at the Buffalo General Hospital, Surgical Clinic.

BY ROSWELL PARK, M.D.

ON March 2d, a portion of the Niagara Falls tunnel caved in, and two men were killed by the falling débris. A third man was struck in the dorsal region by a beam, had the right humerus fractured in two places, and was bruised about the face and body. His lower limbs were found to be paralyzed and without sensation. He was sent by train to the Buffalo General Hospital and examined by Dr. Parmenter, who found a depression in the course of the spinal column, indicating either fracture or dislocation. On gentle manipulation crepitus was elicited, showing that there was at least fracture, if not also dislocation of the vertebræ. The injury to the cord must have been at about the level of the tenth or eleventh dorsal vertebra. Sensation was preserved to a line just above the pubes in front, passing near the anterior superior iliac spines at the sides, the limitation of sensibility corresponding to the course of the spinal nerves.

Obviously, without operation it could not be determined whether the cord was simply compressed or also lacerated. I, therefore, cut down over the line of the lower dorsal and upper lumbar vertebræ. Almost as soon as the knife passed through the skin, at least as soon as the fascia was penetrated, it was evident that the tissues were greatly lacerated, and lying upon the

bone I found a piece of spinal cord. This put almost a hopeless aspect on the case, but I thought it best to continue the exploration, and entered the spinal canal by removing the arches of the tenth, eleventh, and twelfth dorsal vertebræ, finding the canal—which in this situation is about the size of my little finger—filled with shreds of spinal cord and blood. There was still a portion of the cord apparently intact. After removing the projecting bone and other sources of irritation and compression, the wound was closed and dressed antiseptically. Judging from the mass of débris of the cord and clots found, the violence must have been extreme, and as only one spinous process was driven in, the traumatism must have been inflicted by the corner of a beam.

The man's temperature, three days after the injury, is only a little above 99°. He has had no disturbance following the operation. His paralysis is neither greater nor less than before. If septic meningitis were to ensue, I should expect it to-day, and as there are no signs of it, I infer that he will escape that danger. If so, he will probably get well after a fashion, but it will be a matter of extreme interest to note what reparative changes, if any, occur in the cord. The patient and his friends say that they would rather have him die than live in his present condition. The prognosis, as far as recovery of the functions of the cord is concerned, must necessarily be as unfavorable as possible.

(The patient subsequently made a good recovery, so far as the operation was concerned, the wound healing by first intention under one dressing. The only incident was a slight cystitis. The line of anesthesia descended a little, but otherwise the paraplegia remained unaltered.)

The second patient, thirty-seven years old, presents well-marked kyphotic curvature of the spine in the upper dorsal region, as the result of Pott's disease, the activity of which subsided many years ago, and which may be regarded as cured by ankylosis of the vertebræ. Otherwise he was in good health until March 18, 1892, when he was struck by a train and bruised about the back. The ambulance was immediately summoned. On its arrival, the patient was found to be but partially paralyzed, but within an hour he became completely so. The case is not yet twenty-four hours old, and now, upon examination, it will be seen that there is complete motor paralysis below the waist, and apparently complete loss of sensation. On careful examination, however, it appears that the anesthesia is simply cutaneous and that the patient has not lost the muscular sense. For instance, he cannot tell when the right foot is touched, but when it is firmly flexed or extended he is conscious of the movement. The muscular sense is less impaired on the right than on the left side. Tracing the line of cutaneous anesthesia, the evidence points to a lesion at about the level of the eleventh dorsal vertebra. We have to distinguish between fracture of the vertebræ, with compression of the spinal cord at this level, and an intra-spinal hemorrhage. The diagnosis is made mainly by relying on the history of accident and that which the ambulance-surgeon gives us. We are told positively that paralysis was not complete when the ambulance arrived, some twenty or thirty minutes after the accident, but that it became so within an hour afterward. This statement would seem susceptible of but one explanation, namely, that of hemorrhage, with the formation of a clot gradually increasing in size, and pressing more and more upon the cord. Whether this clot is extra-dural or intra-dural, or due to a lesion of the cord proper, it is impossible to say. The evidence, however, points to pressure upon the cord at the level indicated, and the patient has willingly assented to an endeavor to afford relief. Accordingly, I purpose performing laminectomy, or as it is sometimes called, trephining the spine—in other words, cutting down upon the spinal column, exposing the spinal canal, and probably opening the dura and examining the cord itself.

The patient being anesthetized, a long incision is made and the muscles on either side of the spinous processes of the ninth, tenth, eleventh, and twelfth dorsal vertebræ are separated and retracted, so as to expose in a measure the posterior surface of the spinal column. The spinous processes are removed with stout cutting-forceps, and the laminæ are divided with the forceps and chisel, until the spinal canal is open for a distance of six or seven centimeters. You will remember that there is a plexus of veins between the bony canal and the dura, and if the hemorrhage were extra-dural, we should expect to find here evidence in the shape of blood-clot. Little or nothing of this is apparent, and I shall next open the dura. The dura is opened by raising it at one point with a tenaculum, dividing it with a sharp-pointed knife, and slitting the membrane with a blunt bistoury. At the point where I raise the dura, it seems darker in color and gives the appearance of a dark mass seen through a nearly opaque membrane, although under the finger the sensation is not distinctive. Upon opening the dura, it is seen that there is a considerable quantity of effused blood, and upon clearing this away, the integrity of the cord itself does not seem materially impaired. Evidently, then, the diagnosis of hemorrhage was correct, and upon the removal of this laminated clot, we afford the patient a chance for recovery, of which he would otherwise have been deprived. If, now, there be no other lesion, and if no septic or other accident occur, we may regard his future as hopeful. In this instance I shall not close the dura carefully, but place only one or two stitches and trust further repair to natural processes. I do this for two reasons: First, because of the length of the procedure, since at this depth and working within narrow confines, an accurate closure would be most difficult and time-consuming, and unless the opening be accurately closed to prevent leakage there is no particular object in closing it at all. My second reason is that experience has taught me that the dura heals just about as well when not sutured as if it were sutured.

One other point about this patient I have not mentioned, namely, that from the time of the accident he has had bloody expectoration, and now, on physical examination there is found a limited area of dulness over the right lung. I do not detect crepitus, as from a broken rib, but, nevertheless, I cannot forget that some injury either to rib or lung, or both, may complicate the case in a most undesirable way. The extensive superficial wound is closed with two tiers of buried sutures of catgut and one superficial layer through the skin. Over this a carefully applied aseptic dressing is laid.

The patient lived about a week. The wound healed without complication, but the patient's paralytic condition was in nowise improved; his lung-trouble increased somewhat in extent, and he died apparently from marasmus and weakness as much as from any appreciable cause. On autopsy it was found that there had been no fracture and no serious injury to the cord at the level of the operation, but at a higher level, at the point of angular deformity to which attention was called, there had been fracture and displacement, with compression of the cord. There were no evidences of septic meningitis. During life there had been nothing, either in the way of tenderness or alteration in contour, to call attention to this higher lesion in the spine, and certainly a study of the nervous distribution of the paralyzed and non-paralyzed parts gave no indication that the primary cause of the paralysis was located here. Attention is called to this case as illustrating an unusual complication in spinal injuries, and as possibly pointing out a clear indication for operations in the future.

CLINICAL MEMORANDA.

CHOREA; ENDOCARDITIS; DEATH.[1]

BY H. K. AIKEN, M.D.,
OF LAURENS, S. C

THE following case is reported as affording some additional evidence upon the association of chorea with a rheumatic diathesis, and also as an illustration of the hereditary transmission of rheumatoid tendencies through three generations. In this instance a severe endocardial inflammation followed chorea, without the intervention of any arthritic symptoms.

On the evening of February 4, 1892, during the absence of the attending physician, I was asked to see B. J., a white female, ten years old. At my first visit the pale-faced, anemic child was lying crosswise in bed, with her chin flexed on her chest and the legs upon the abdomen. When approached by anyone, she begged to be let alone. Attempts at examination provoked fits of crying. The pulse was too rapid for me to count. Her tongue was coated with a pasty, white fur, its edges and tip being a deep red. The lips were cracked and fissured. The temperature taken in the axilla was 103°. The heart's action shook the chest-walls and was so tumultuous as to make a satisfactory physical exploration of the chest impossible at the time. The child had a slight cough, but there was no dulness on percussion; on auscultation the vesicular murmur was heard to be roughened. There were pain in the right iliac fossa, epistaxis, mental hebetude, a desire to be let alone, with a history of nausea and vomiting, together with irregular chills. Emaciation was marked and the adynamia profound. I prescribed a fever-mixture containing aconite, and left with a diagnosis of advanced typhoid fever almost settled upon. By the following morning the heart's action was reduced so that the condition of this organ could now be studied. There was at once apparent a soft, blowing, systolic murmur, heard best at the apex, and not transmitted to the back.

From the attending physician, who had now returned, I learned the previous history of the case, together with these additional facts: The child had been sick for six or eight weeks, with intervals of improvement. During the summer and fall of 1891 she had chorea, which entirely disappeared after the use of the officinal solution of potassium arsenite. The girl returned to school, but continued listless and complaining. Choreic movements again appeared in December, 1891, when she was put back on arsenic, and the dose increased to fifteen drops, t. i. d., before any edema was produced. The dose was then decreased, and arsenic, with the addition of an iron, quinine, and strychnine tonic, continued until all spasmodic movements had disappeared. During this period the child complained of pains in the muscles of her right leg, but these were ascribed to influenza, then prevalent. She had not shown choreic movements for a month. Her temperature had lately been ranging between 101° in the morning and 103.5° in the evening, with daily or tertian chills. The chill, or cold stage, would be followed by a typical hot stage, and a sweating stage. Cough first appeared during the week previously to my seeing her, and had been increasing in frequency. There was no expectoration. The child's mother had died in the same room, ten days before, of unmistakable pulmonary tuberculosis, of fourteen months' duration.

Reviewing all the facts in the case, it seemed that we had here to deal with either enteric fever, endocarditis, a malarial remittent, or tuberculosis florida. The diagnosis of endocarditis in a child of ten is not easy, and is masked by the resemblance of its symptoms to those of other and commoner diseases. I will briefly detail the steps by which such a diagnosis was arrived at in this instance.

Enteric fever was excluded—because, although the temperature made an evening rise and morning fall, the variations were too great; and because of the absence of eruption, diarrhea, and tympanites; the stools were solid and without peculiar odor.

In favor of a diagnosis of pulmonary tuberculosis was the fact that there had been ample opportunity for direct infection from mother to child. Both were sick in the same room; both were coughing; both emaciating. The absence of consolidation, however, the sudden onset of serious symptoms, and the high temperature-range seemed to exclude tuberculosis.

After the chills, the temperature would rise rapidly and decline with the sweating stage. In this locality, the possibility of a malarious influence cannot be overlooked; but a remittent was excluded, because quinine had no effect upon the fever; the prostration continued between the paroxysms. The season of the year was also against such a diagnosis—this section being almost free from malaria during the winter months.

A diagnosis of acute endocarditis was therefore made, based upon the past history, the irregular chills, nausea and vomiting, the high temperature and the overacting heart, with a soft bellows-like murmur of organic origin. The attending physician stated that he had repeatedly examined the heart and found no murmur. In this case, it must have developed rather suddenly, and was not perceptible until late in the disease, the time at which I was called to see the case. There were no evidences of pericarditis.

[1] Read before the Laurens County Medical Society, March 27, 1892.

Accepting this diagnosis, appropriate treatment was begun. As long as hypertrophy kept up, reliance was placed upon tincture of aconite with alkalies, principally potassium bicarbonate. A blister was applied to the precordium. On account of continuous nausea, it was with difficulty that enough medicine could be retained to produce any effect upon the advancing disease. The irritability of the stomach was best controlled by minute doses of calomel, which was also given for its antiphlogistic effect. When compensation began to fail, we employed digitalis, strophanthus, and alcoholic stimulants, but with little success. An unfavorable prognosis had been given the family, after which they gave up hope, and it was hard to get any treatment properly carried out. The child was so ill that they seemed indisposed to disturb her to give food or medicine. We endeavored to maintain nutrition by using peptonized milk, nourishing broths, and liquid beef-peptonoids. Despite our endeavors, the temperature continued high, the powers of circulation and assimilation gradually failed, until insomnia and general venous stasis closed the scene. Death took place rather suddenly, three weeks after the onset of the acute symptoms. An autopsy was not allowed, and so the diagnosis could not be verified.

The family history of this little patient is interesting. She belonged to a strongly neurotic family. Her mother's father and her father's father both suffered with rheumatism. Her father had a most obstinate attack of sciatica during the fall of 1891. A brother had chorea at the age of twelve. An older sister has also had chorea. Both recovered after treatment with arsenic. I am uncertain whether this case was one of simple or of septic endocarditis. The rigors, the high temperature, the early development of the typhoid state, would seem to point to a septic origin. But there was no wound, while the existence of a rheumatic diathesis can hardly be questioned.

Chorea is not uncommon here. The statement made by Dr. Mitchell, and often quoted, that the disease never occurs in the negro race, I had no reason to doubt until recently. A *negro* boy (not a mulatto) between twelve and fourteen years old, living on a farm in the country, was brought to me, suffering with chorea. He was given Fowler's solution of potassium arsenite, and improved. This is the routine treatment. The dose is at first from three to five drops, and is increased until the symptoms abate or the point of tolerance is reached.

MISTLETOE AS AN OXYTOCIC.

By HAMILTON P. HOWARD, M.D.,
OF BIG STONE GAP, VA.

DR. W. H. LONG, of the U. S. Marine-Hospital Service, in *New Preparations*, in 1878, claimed for mistletoe, as compared with ergot, for oxytocic purposes—first, that it acts more promptly and surely; secondly, that it produces *intermittent* uterine contractions, as opposed to *tonic* contractions, and for this reason it may be used in *any* stage of labor or in primiparæ. These claims he bases on an "extensive experience of its use between the years 1867 and 1878," and such was his uniform success with it in "hundreds of cases," that he reports, to use his own words: "It acts with so much more promptness and certainty than ergot that I have been using it exclusively for years." With equal earnestness Dr. Long also advocates the use of mistletoe in menorrhagia and post-partum hemorrhage and in hemoptysis.

A drug that could be depended upon to induce with certainty *intermittent* uterine action would prove a boon to the obstetrician, not only in cases in which the induction of labor was indicated, but also, and more particularly, when pains are absent at term or have ceased from atonicity of the uterus. I am induced to report my own limited experience of mistletoe in the hope that further trials and reports of it may be made.

Mrs. J. B. A., thirty-six years old, had a history of eight abortions and miscarriages — the last at eight months, the remainder dating between the third and the sixth month. The patient first came under my care at third month of gestation, and was with difficulty carried to full term, her pregnancy being complicated by frequent attacks of cardiac asthma and a prolonged siege of general peritonitis brought on by rupture of adhesions due to old pelvic inflammation. She gave, further, a history of protracted labors, with profuse and persistent post-partum hemorrhages, not only in the premature birth, but also in all the abortions and miscarriages. In her own words, "her pains always died out," and artificial aids to delivery had to be employed. The child at eight months was born only after a week of interrupted labor, and then was "removed"; and I gather that ergot was freely used in this instance.

In her last labor, the outcome of which was a well-nourished and healthy six-and-a-half-pound girl, I made use of mistletoe, using the fluid extract in one-dram doses at intervals of twenty minutes for four doses. The circumstances and nature of the case were such that I deem it quite a crucial test of the drug. During my absence in another part of the State her labor began, and, according to her own statement, the pains were the strongest she had ever felt; they, however, only persisted for from twelve to fifteen hours. On my return, five days later, I found her utterly devoid of pains, the os dilated to the size of a half-dollar, soft, and non-resistant. On introducing two fingers, which were readily admitted, I made out a normal L. O. A. position. After waiting for two weeks for a renewal of pains, which I was unable to induce either by uterine compression, digital dilatation of the os, or suppositories of quinine, belladonna, and strychnine, I determined to make a trial of mistletoe, of which I had secured a specimen of the fluid extract with a view to its possible use in this case. Twenty minutes after exhibition of the first dose I was gratified by the commencement of excellent dilating pains, and, giving the second dose, I returned to my office for my satchel. Half an hour later, on my return to my patient, I found the labor progressing most satisfactorily. I gave the other two doses at irregular intervals, when the pains seemed to become a little irregular and less strong, but more as a preventive than because imperatively needed. In a little over five hours after giving the first dose of mistletoe the labor, which had been characterized by typically normal uterine action both as to strength and regularity, was terminated, the third stage being ended by the pain which followed the expulsion of the child. The uterus contracted firmly and promptly, with virtually no hemorrhage.

In this case delivery was almost entirely dependent upon uterine action alone, the condition of her heart making sustained abdominal effort impossible—a condition which, I felt convinced, would have led to a fatal termination had the labor been unduly prolonged, there being a double mitral lesion and marked enlargement, and, I think, failing compensation. The fact of her being so entirely dependent upon unassisted uterine action, I think, adds evidence to the character of the pains induced.

The following case in evidence of the action of mistletoe as an oxytocic I am enabled to report through the courtesy of my friend, Dr. C. D. Kunkel, of this place, in whose practice it lately occurred:

——, non-pregnant, was prescribed teaspoonful doses of the following mixture at four-hour intervals: Ext. pichi fl., f℥iijss; ext. mistletoe fl., f℥jss. After taking four doses, containing seventy-two minims of mistletoe, she sent for Dr. Kunkel, complaining of violent "cramps," which, upon investigation and careful examination, were found to be due to characteristic "labor" pains. These pains persisted for from four to six hours, and were strong and regular. The drug had been given on account of its antispasmodic properties, with pichi, in a case of cystitis with violent tenesmus.

EXTENSIVE TREPHINING FOR THE RELIEF OF EPILEPSY FROM TRAUMATISM; COMPLETE RECOVERY.

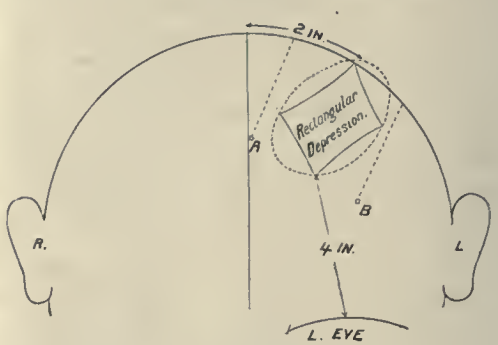
By J. T. BINKLEY, Jr., M.D.,
of Chicago, Illinois.

In March, 1891, O. D., thirty-seven years old, applied for treatment for fits. In 1875 he was hit upon the head with a hatchet, and was unconscious for several hours. He was able to be out after a few days, but had two or three convulsions monthly until June, 1883, when Dr. Bevan, of Gadson, Ala., removed a few small pieces of bone. He was then much improved, but not entirely relieved. On the 11th of July, 1885, Dr. Sheminick, of St. Paul, removed a few more fragments, and the patient was entirely relieved until December 17th, following, when he was struck upon the head by a falling telephone pole. He had convulsions on the same day, and daily thereafter until April 8, 1886. From that date the intervals between convulsions grew longer and longer, sometimes two and three months elapsing, the convulsions occurring when the patient had been drinking.

About a year before the patient came to me, he was taken into the Tacoma Fire Department, where he remained until he had a violent convulsion, following a spree. He was immediately dismissed from the department, began to drink freely, and had convulsions daily. When he came to me, he said: "I had twenty-eight fits yesterday, and have had from two to ten almost daily for four months."

On examination I found a rectangular depression, as indicated in the accompanying diagram, and I decided to trephine.

The individual was without money, but the chief and boys of the Fire Department contributed the hospital expenses, and he was admitted to the Fannie Paddock Hospital, of Tacoma, Wash., late in April, 1891. On the 20th of May, assisted by Drs. Hickman and Philpot, the head having been shaved, antiseptically cleaned, and the patient etherized, I did the trephining. I made a U-shaped incision, the lines of the incision starting on either side of and well in front of the anterior border or angle of the depression, as indicated at *A B* in the illustration, and extending well backward and to the left beyond the posterior margin of the depression, the loop of the U extending down to the middle of a line from the left ear to the occiput. The flap was dissected up—integument and periosteum separately—from behind forward, and both layers of flap turned down over the bridge of the nose. The periosteum was firmly adherent to the dura mater in a small area in the center of the depression, where bone was missing; much difficulty was



A, B. Anterior points of the U-shaped incision. The dotted oval indicates the area of bone removed.

experienced in the separation. When this was accomplished, the finger could detect a well-marked marginal depression of the inner table of the skull, and a fibrous thickening of the dura. The opening through the skull was too small to permit the use of a rongeur forceps, and we bored through on one side with a trephine, then with the rongeur forceps cut away the entire depressed margin of the skull. The bone was unusually hard, so that it was necessary for the gentlemen present to take turns at the trephine and forceps. After we had removed all the bone over a space as large as a silver dollar, no further depressed points could be felt. Small patches of thickened dura were snipped off, and catgut passed around the bleeding vessels and tied. Bleeding from the bone was slight, and controlled by plugging or by caulking with catgut. The oozing was checked by means of hot sponges (too hot, I believe, and responsible for the subsequent suppuration), firmly held for a few minutes upon the exposed surface; the flaps were stitched back separately with catgut, the wound was dressed antiseptically, and a roller cap-bandage applied. The patient rallied well, but was hard to control; he would get out of bed hourly after the second day, when not closely watched. He said "he felt as well as ever, and had missed his fits."

On about the fifth day, a little discoloration of the dressing over the left ear caused me to remove the cap. The wound was found suppurating freely. I syringed it thoroughly and changed the dressing daily for ten days thereafter, when the wound began to improve. As I was coming East, I left the case in the hands of Dr. Hickman, who attended it for two weeks, when the wound was healed and the patient dismissed. There has never been any pain or recurrence of convulsions

since. A letter from Dr. Hickman, dated Tacoma, November 12, 1891, seven months after the operation, reads: "Our patient has never had another convulsion, and I consider that he is radically cured."

A letter from the patient, dated December, 1891, says: "I never have had a pain or a fit since the operation, and I am working every day."

Although this case adds valuable testimony to our knowledge of the surgery of the brain, and the happy results of trephining depressed areas, there is another interesting feature that merits consideration, viz.: the effect of stimulants upon persons subject to convulsions. Here was an individual, predisposed to fits because of an injury, who, when abstemious, was free from convulsions from 1886 to 1891—nearly five years; and who, under the excitement of intoxicants and consequent increased blood-pressure, relapsed into a miserable epileptic within a fortnight.

A CASE OF ABSCESS OF THE TEMPORO-SPHENOIDAL LOBE, AND OF THE MIDDLE LOBE OF THE CEREBELLUM.

BY FRANK P. NORBURY, M.D.,
ASSISTANT PHYSICIAN, ILLINOIS CENTRAL HOSPITAL FOR THE INSANE, JACKSONVILLE, ILL.; FORMERLY ASSISTANT PHYSICIAN, PENNSYLVANIA INSTITUTION FOR FEEBLE-MINDED CHILDREN, ELWYN, PA.

F. M., a married farmer, thirty-two years old, was admitted to the Illinois Central Hospital for the Insane four weeks after the development of insanity, a cause for which could not be determined. But little of the previous history could be learned. Several weeks previously to admission to the hospital, the patient complained of severe headache, and he became dull and stupid. A short time afterward "he had seven fits." On admission, no symptoms of organic brain-disease were observed. Three days later, however, it was noted that the gait was cerebellar; vertigo was complained of; ptosis appeared, and some aphasia was evident. The condition continued for several weeks, when early one morning the man had a severe convulsion, followed by vomiting. Seven hours later he had another attack of vomiting, followed by apoplectic symptoms. He became unconscious, with face turgid; frothy mucus was discharged from the mouth; respiration was slow and labored; the pulse was bounding; the temperature was 100.2°; there was conjugate deviation of the eyes downward and to the right; the pupils were insensible to light; there was left hemiplegia, with some hemianesthesia; there were no muscular contractions; the bowels moved involuntarily. On the following, day the paralytic symptoms were more extensive, the muscles of deglutition being involved. Coma was profound; the temperature was 101.2°; the pulse 89; the respiration 40. There was some pulmonary edema. A day later, the pulmonary edema was more pronounced; the pulse was 94; the temperature 100.4°; the respiration 42. Ptosis of the right side was now observed. The next day brought little change. The pulse was 98; the temperature 99.2°; the respiration 36. On the following day the pulse was 120; the temperature 101.2°; the respiration 56. The patient went into a state of collapse, from which he failed to emerge.

A post-mortem examination was made thirteen hours after death. The dura mater was found adherent in the occipital region, just above the internal occipital protuberance, in an area an inch and three-quarters by half an inch. The meninges were engorged on the right side. The pia was adherent to the cerebrum beneath the area referred to. On cutting through the falx cerebri, cheesy material was found attached to it. On removing the brain, shreds of broken-down brain-substance and pus were noticed at the base. On section of the brain, an unencapsulated abscess was found in the right temporo-sphenoidal lobe, extending to and opening into the lateral ventricle. The centrum ovale was uninvolved. The mass of disorganized brain-substance was not purulent. A deposit of pus was found at the base, in the region of the motor oculi nerve. Further section revealed the existence of an abscess in the middle lobe of the cerebellum.

The presence of a lesion of the cerebellum had been diagnosticated from the pressure-symptoms, the vomiting, the titubation, and the ptosis, but tumor was suspected, and not abscess. The terminal symptoms of the abscess of the temporo-sphenoidal lobe simulated those of cerebral hemorrhage. The perforation into the lateral ventricle, however, affords the explanation. Pressure in the region of the internal capsule will account for the temperature-range, and the involvement of the fourth ventricle for the varied motor symptoms. The temperature-range may also be explained by the inflammatory process in the ventricles. The probable cause of the multiple abscesses was a traumatism in the occipital region at a point externally corresponding with the localized adhesion of the dura internally. There were no evidences of ear-disease, necrosis of bone, or previous suppurative process elsewhere.

The case reported is interesting, first, because of the obscure symptoms attending the abscess in the temporo-sphenoidal lobe and the existence of marked signs of cerebellar pressure; and, second, because of the infrequency of multiple abscesses from traumatism in the regions occupied.

The latent abscess terminated precipitately, hence the apoplectic character of the symptoms.

A CASE OF COMPLETE OUTWARD DISLOCATION OF THE RADIUS AND ULNA AT THE ELBOW; REDUCED AFTER DIVISION OF THE TENDON OF THE TRICEPS.

BY JOHN HOMANS, M.D.,
VISITING SURGEON TO THE MASSACHUSETTS GENERAL HOSPITAL.

IN THE MEDICAL NEWS for July 11, 1891, Dr. Isham, of Cincinnati, has reported a case of outward dislocation of the radius and ulna, and he states that the whole number of cases reported in the United States is fifteen. I wish to add another, the first and only case I ever saw. The case was a chronic one of three weeks' standing. The elbow was sore, inflamed, and swollen. On this account the dislocation was more difficult to reduce, and the resulting disability has been greater than it would have been in a similar case received immediately after the accident. Oren G., fifty-seven years old, a farmer entered the Massachusetts General Hospital, June 3, 1891, stating that three weeks previously he had fallen

from a tree, striking his right elbow. He felt something crack in the joint, and immediately sent for a physician, who etherized him and put the arm in splints. When the splints were removed, the arm, forearm, and elbow were found ecchymosed, swollen, and tender. The arm was useless, and any movement of it caused intense pain. A consultation was held, and it was decided to send the patient to the Massachusetts General Hospital. On examination, I found the condition of the arm described; very little flexion, pronation, or supination could be performed. The forearm was carried at an oblique angle with the arm. The inner condyle stood out under the skin in plain outline, and the integument looked as if it would burst, while the head of the radius, with the olecranon and coronoid process of the ulna, all uninjured, lay to the outer side of the external condyle. After etherization, the adhesions were broken up by passive motion, and prolonged attempts at reduction were made patiently and carefully, but with much force and without result. Dr. C. B. Porter, the senior surgeon of the hospital, suggested division of the tendon of the triceps. After this was done, reduction was easily accomplished. An internal angular splint was applied and a drip of cold water was kept upon the limb, on account of the heat, swelling, and tenderness. The forearm was gently flexed and rotated on June 15th.

On June 25th the man could flex and rotate his forearm, but the joint was somewhat stiff and sore. As he appeared to be an intelligent American farmer, and would probably follow my advice in regard to using his arm, I thought he would get along better in his own home than in the hospital, and on June 23d he was discharged.

I have not seen him since, but have heard from him several times. Perhaps his own words and expressions will describe the present condition and usefulness of his arm better than I can do. It is not to be expected that a man, fifty-seven years old, with more or less rheumatic stiffness of his joints, who has had a displacement of the elbow unreduced for three weeks, will recover perfect motion and usefulness of his arm. It is interesting and important to know what his present condition is—nine months after the injury. I append a letter just received from him:

FEBRUARY 23, 1892.

DEAR SIR: Your letter of inquiry has been duly received. It is difficult for me to write just how much I can use my arm. There are many little things I can do, and some which I would like to, I cannot do. I can raise my arm to the top of my head, but not as easily or as quickly as one with a perfect elbow. I feed myself some and cut meat with the right hand, but it seems rather awkward, and I want plenty of room in which to do it. The fingers are stiff, but they were so before the accident, and the whole arm is so weak that I cannot grasp or hold much of any weight. The hand is very sensitive to cold. There is stiffness in the elbow, so that I cannot quite straighten the arm. But withal I find it very helpful every day—more so than I can express; and judging from the past I think it will continue to improve.

Yours truly,
OREN G.

A CASE OF TONSILLITIS; TRACHEOTOMY.

BY C. M. McGUIRE, M.D.,
OF SEYMOUR, IOWA.

ON the morning of April 7, 1892, Dr. Eva M. McGuire was called to see a rather poorly-nourished, breast-fed female infant, of healthy parentage, eight months old. The infant was restless, with an axillary temperature of 100° F.; the pulse was 120, the respiration 30. No abnormality was detected in the lungs or in the fauces. The right parotid gland was swollen, and somewhat tender. A mercurial, to move bowels, and phenacetin, gr. ij, every three hours, alternating with potassium bromide, gr. iv, were prescribed, and it was directed that hot fomentations be applied to the parotid gland.

On the morning of April 9th, Dr. McGuire was again called to see the infant. The parents feared that pneumonia had set in. Careful examination failed to discover any abnormality of the lungs. Temperature, pulse, and respiration were about the same as at the first visit. The right parotid gland was more swollen, and the left seemed enlarged. The right tonsil also was slightly swollen and red. No white patch, no membrane was apparent, and there was no hoarseness. The jaws seemed stiff when an attempt was made to open the mouth. The infant had continued to nurse, but would hardly take the medicine. Tincture of aconite was added to the potassium bromide solution; whiskey and cream were ordered to be given every four hours, and hot fomentations to be applied to the parotid glands. The child was playful on April 10th. It took food and medicine until the evening of April 11th, when it would not nurse or take its medicine. The right parotid gland was now greatly swollen and hard; the left not so much so; the mouth was opened with much difficulty. On examination of the fauces both tonsils were found greatly swollen and red, more especially the right. The infant cried continually from 9 P.M. until 4 A.M., except for an interval of about an hour and a half, during which it slept under the influence of opium.

Tincture of opium was given in full doses per rectum, and phenacetin by the mouth. The tonsils were freely and frequently swabbed with hydrogen dioxide. The infant's breathing was difficult, owing to the swollen tonsils. I was sent for at 3 A.M., and advised tracheotomy as the only chance for the infant's life. Dr. Earnest, of Seymour, was also sent for, but before he arrived the parents urged the operation, which was performed by Dr. Eva McGuire and myself, with the aid of the light from a poor oil-lamp. Not having a silver canula, we used a new sterilized, No. 14, American, soft-rubber catheter, held in position by a safety-pin. The infant was anesthetized by means of chloroform. The tube was inserted just below the first cricoid cartilage. The hemorrhage was slight. Sublimate cotton, frequently moistened, was kept around the tube, and moist sublimate gauze kept over its orifice. The atmosphere of the room was kept moist by boiling water on a stove constantly. The infant breathed easily through the tube for awhile; then artificial respiration had to be employed for two or three hours. The child seemed to be doing well, but in twelve hours from the time the tube was introduced the action of the heart ceased. The infant had taken its medicine and food quite well. No fluctuation could be detected in the parotid gland or

tonsil, and there was no rise of temperature until a few minutes before death. There were no rigors or chills, denoting the presence of pus; no hoarseness at any time, denoting edema of the larynx. I report this case because I have been able to find no other in which inflammation of the tonsils appeared secondarily to inflammation of the parotid glands.

PILOCARPINE NITRATE IN FACIAL ERYSIPELAS.

BY G. V. HALE, M.D. (JEFFERSON),
OF WHEATLAND, TEXAS.

PERHAPS none of the common diseases with which the general practitioner is daily compelled to grapple causes him more perplexity and embarrassment, as it continues to advance in spite of scientific therapeusis, than that well-named ancient and modern "Fire Erysipelas." The affection is especially indigenous to this locality and State, and from quite an extensive acquaintance with it in patients of all ages, I feel it a duty to record the satisfactory results obtained from the use of pilocarpine nitrate administered hypodermatically in aqueous solution, in doses of from one-fortieth of a grain for infants to half a grain for adults—the dose at all events being sufficient to maintain a steady appreciable diaphoresis; stimulants being given at the same time, as required. In submitting my experience with this remedy I am neither unduly enthusiastic nor am I unmindful that in the treatment of erysipelas the great master Trousseau "used no remedies except a laxative, but he pushed the administration of food—which must be done, of course, in all cases—and of the great number of cases treated by him only three died."

Two cases of facial erysipelas in infants—one male, one female—respectively seven and nine months old, with temperature (rectal), when first seen in consultation, of 104° and 105°, cerebro-spinal symptoms, after intelligent treatment by all the usual means, yielded to pilocarpine nitrate in slightly diaphoretic doses, being markedly improved in from twenty to thirty hours and convalescent in a week. The only laxative used was castor oil. In these cases, contrary to my usual experience, we were unable to check the spread of the dermal inflammation. It gradually invaded every inch of skin, even to finger and toe tip; but the advancing line was only of a pale reddish hue. The temperature declined to 100° after the third dose; the infants rested well and nursed again (the breast had been refused and breast milk was administered with a spoon for about thirty hours).

The results of these cases, so unpromising and malignant at first, are entirely consonant with my experience with the remedy in many other cases and the course of the disease in these instances varies only in the failure to promptly arrest the advancing line of inflammation. I began using jaborandi and pilocarpine after listening to the remarks of my honored instructor, Professor Da Costa, concerning jaborandi in erysipelas, at a clinic at the Pennsylvania Hospital several years ago, and have not failed to relieve a single case in which the remedy was employed early enough to have had anything like a fair trial.

MEDICAL PROGRESS.

The Relations of Various Bacterial Poisons to Immunity and Cure.—G. KLEMPERER (*Zeitschr. f. klin. Medicin*, 1892, xx, 1, 2, p. 165) defines toxalbumins as albuminous bodies that result from the growth of bacteria in bouillon. Solutions of toxalbumins injected into animals in small, gradually increasing quantities protect from infection by the respective bacteria. The specific activity of toxalbumins is related to definite temperatures. Proteins, on the other hand, are albuminous substances that are contained within the bacterial organism. They are obtained by boiling pure cultures of bacteria in the nutrient bouillon or in washings in water. The characteristic of proteins is that they are not decomposed by protracted boiling. Tuberculin is the protein of tubercle-bacilli and the only protein that has hitherto been employed to confer immunity and to accomplish a cure. Klemperer has prepared proteins from the pneumonia-coccus, the bacillus pyocyaneus, the micrococcus prodigiosus, the bacterium coli, and the bacillus anthracis. Injected into animals each gave rise to a characteristic reaction, *protein fever*, analogous to that following the employment of tuberculin. Some could be used interchangeably with tuberculin, reaction and tolerance remaining otherwise unaffected—tuberculous animals reacting to either protein and the tolerance established to the one holding good for the other. With none of the proteins employed was immunity conferred or cure accomplished. Klemperer employs the term toxin instead of toxalbumin. He has especially studied the toxin of the pneumonia-coccus. Immunity to pneumonia has been conferred upon animals by treatment with pneumotoxin. Natural recovery from pneumonia depends upon the conversion of pneumotoxin as a result of the pyrexia into antitoxin. Artificial recovery may be brought about by the injection of the serum of an animal in which the toxin has already been converted into the antitoxin. The process of conversion, however, requires several days, and infected animals often die; but the process can be accelerated by heating the toxin prior to injection. The results warrant the conclusion that immunity can be conferred after infection has taken place, by the injection of sufficient quantities of suitably prepared toxin.

Sudden Death from Latent Tuberculous Leptomeningitis.—HERYNG (*Internationale klin. Rundschau*, 1892, No. 14, p. 545) records the case of a boy, ten years old, in which the galvano-cautery was employed in the treatment of a hypertrophic rhinitis. On the morning following an application the boy was found dead. The autopsy disclosed the existence of a tuberculous leptomeningitis, particularly involving the base. In the left occipital fossa, attached to the membranes and lying upon the cerebellum, were two tumors, one as large as a hazelnut, the other as large as an English walnut. On section the growths were found to be caseous at the center; the periphery was infiltrated with round cells; the stroma contained giant cells, with tubercle-bacilli. The upper portion of the left lung was adherent to the costal pleura. On both layers of the pleura miliary nodules were visible. The apex of the lung contained a small number of grayish-white points. The bronchial glands

of the left side were enlarged and caseous; so were the mesenteric glands. The serous layer of the lower portion of the small intestine presented a number of areas occupied by miliary nodules. The mucous membrane of the corresponding portion of the small intestine and of the adjacent portion of the large intestine was covered with grayish-white nodules. It was learned that the boy had had a severe attack of measles a year previously, complicated by exudative pleurisy upon the right. Shortly afterward, after an indiscretion in diet, he had had an attack of convulsions.

Infection-proof and Intoxication-proof.—BRIEGER, KITASATO and WASSERMAN (*Zeitschr. f. Hygiene*, 1892, Bd. xii, p. 91) have made an experimental study of bacterial intoxication. Pathogenic microörganisms may cause symptoms either by their multiplication and general dissemination, or by the absorption of toxic substances produced at the seat of local infection. Some animals naturally resist general infection; others resist intoxication. By certain methods of treatment the protection natural to some animals can be artificially extended to others. An animal may, however, be intoxication-proof, but not immune or infection-proof, and *vice versa*. By the treatment of cultures of the bacilli of tetanus, cholera, diphtheria, typhoid fever, and erysipelas, with an extract of the thymus gland, the virulence of the organisms was diminished, while immunity was conferred; the serum of immune animals had the power of protecting other animals. The results with the bacilli of hog-erysipelas and anthrax were not so conclusive. The conclusion is reached that the protective substances are not contained in the products of tissue-metamorphosis but within the bacterial organism. The characteristics of these substances are as follows: they contain a relatively large proportion of phosphorus; in contrast with toxalbumins, they pass with difficulty, if at all, through porcelain filters; they are destroyed by temperatures of 212° F.—*Deutsche medicin. Wochenschr.*, 1892, No. 14, p. 317.

Thoracocentesis.—At a meeting of the French Academy of Medicine, DIEULAFOY (*L'Abeille Medicale*, 1892, No. 18, p. 137) advocated the employment of thoracocentesis whenever the volume of fluid in the pleura furnished the indication. An effusion of 1800 c.cm. (three pints and a half, plus) marks the limit. Dyspnea as an indication cannot be relied upon, for death may result from the volume of the effusion in the entire absence of dyspnea. Dieulafoy denied that thoracocentesis, properly performed, led to the conversion of a simple into a purulent effusion. He related that he had performed thoracocentesis almost four hundred times, without empyema developing in a single instance.

The Differentiation of Typhoid-bacilli and the Bacilli Coli Communis.—THEOBALD SMITH (*Centralbl. f. Bakteriol. u. Parasitenk.*, 1892, xi, 12, p. 367) refers to the observation made by him in 1889 that typhoid-bacilli on the one hand, and colon bacilli and other organisms found in the intestinal contents of man and animals on the other hand, are to be distinguished from one another by the fact that the latter in culture cause decomposition of glucose with the evolution of gas, while the former do not.

THERAPEUTIC NOTES.

Lactic Acid for Tuberculous Fistulæ.—ZIPPEL (*Centralblatt für Chirurgie*) recommends the topical employment of lactic acid in the treatment of tuberculous fistulæ. Protracted application is necessary, and this is secured by means of suitably prepared bougies. To this end, equal parts of gelatin, lactic acid, and water are thoroughly mixed and gently warmed, while 20 per cent. of menthol is added; the mass is poured into moulds, which are for twenty-four hours placed in an ice-chest. The rods are then placed in an exsiccator over calcium chloride. At the expiration of eight or ten days they are covered with collodion. Before being used they are cut cone-shape at one extremity, and are then ready for introduction. If the sheath of collodion is objectionable, the rods may be kept in oil or in benzine to which 30 per cent. of menthol has been added. Menthol is added to diminish pain. If starch with tragacanth be substituted for the gelatin, the rods are harder and less elastic.—*Wiener medizin. Presse*, 1892, No. 15, p. 596.

Goiter Successfully Treated by Injections and Enucleation.—O'REILLY (*Lancet*, No. 3579, p. 741) has recorded the case of a woman, forty-two years old, who presented an immense cystic goiter of thirty-six years' standing. By means of a "double-barrelled" syringe of special device some of the contents of the mass were withdrawn, and solutions of mercuric chloride, resublimated iodine, and potassium permanganate alternately injected. After two months' treatment, in the course of which some seventy injections were made, the tumor was reduced to one-third of its original size, and the symptoms previously present relieved. A radical operation was now decided upon, and the entire right lobe of the gland, weighing more than two pounds, was removed. The patient made an excellent recovery, the left lobe undergoing spontaneous reduction in size.

Black Snakeroot for Dysmenorrhea and Ovarian Irritation.—From the results obtained in a series of cases JAMES BRUNTON (*Practitioner*, xlviii, 4, p. 265) concludes that *actea racemosa* (black snakeroot) possesses anodyne properties and may, with advantage, take the place of bromides and opiates for the pain of dysmenorrhea. In addition, the drug has a direct action on the uterus, increasing the menstrual flow when scanty. It is best administered in doses of thirty minims, thrice daily, beginning three days before and continuing throughout the period. It is sometimes useful in menorrhagia and metrorrhagia. Its action is almost specific when there are ovarian pain and nervous depression.

For Tapeworm.—

℞.—Strontii lactat. . . . . ℈iv.
Aquæ destillat. . . . . f℥j.
Glycerini . . . . . q. s.—M

Sig.—Two teaspoonfuls daily in the morning for five days.—LABORDE, *Journ. de Med. de Paris*, No. 15.

Atropine for Gastric Hypersecretion.—In a case in which the gastric juice was secreted in excess, and other measures had failed, VOINOVITCH obtained curative results by the administration of one one-hundredth of a grain of atropine three times daily.—*La Sem. Mèd.*, No. 17.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. SATURDAY, MAY 14, 1892.

THE AMPLIFICATION OF THE QUARANTINE SERVICE.

QUARANTINE, thoroughly organized upon a scientific basis and judiciously and skilfully conducted, not only protects the public health but facilitates commercial intercourse. It seeks first of all, by its far-reaching influence and coöperative organization, the prevention of disease as the surest way of preserving the public health and uninterrupted commercial communication. Failing in this, it aims, in the second place, at the prompt suppression of disease with least embarrassment to commerce. In order to accomplish the first object, it is manifest that a system must be adopted that extends its surveillance to foreign ports. To some extent, this is now done by consular agents and special officers acting under the sanction and direction of the national authority, and with the acquiescence of foreign governments. But ideal results can only be obtained by a well-organized system operated under international coöperation and made to apply to ports of departure as well as to ports of entry, and extending its supervision over vessels on the high seas. So comprehensive a scheme necessarily involves the assumption by the government of the control of quarantine.

Quarantine is the necessary interposition of sanitary surveillance for the purpose of detecting and excluding dangerous communicable diseases. It is not necessarily burdensome, but must, at whatever cost, effectively guard the public health; otherwise it is an expensive formality, obstructive of commerce without yielding any compensative advantages. If wisely and efficiently carried out and supported by intelligent and full coöperation of other countries, under proper international agreements, it is not only preventive of the introduction of disease, but a positive advantage to commerce by avoiding those calamities that, in the absence of regulations or from their lax administration, occasionally must happen and disrupt for the time commercial intercourse and seriously embarrass trade.

The fundamental principle of correct quarantine administration is the prevention of disease. The neglect of measures of prevention abroad necessitates the provision of regulations at home to meet all possible consequences. By reason of limited jurisdiction and scope of authority, quarantine has hitherto concerned itself almost exclusively in the restriction and suppression of disease. The imposition of disabilities has its salutary effect. It is more through fear of the consequences than by the exactions of law that measures of precaution are observed. So long as authority is hemmed in by local bounds, just so long will progress in the development of the highest function of quarantine service be obstructed.

The prevention of diseases involves a knowledge of their nature, origin, and causes, and the continuous and assiduous application of measures based upon such knowledge. It is not the want of knowledge, but the neglect to profit by it, that brings disaster upon the commerce of the world. The great fault in existing systems is the lack of concern with regard to the condition of departing vessels. Bills of health are optional, and not mandatory as they should be. The opportunity to evade wholesome restraint is seldom barred. Hence the assumption of risks by ignoring prudent measures of protection, which provokes calamities that are often visited upon the unoffending. Flagrant defiance of humane precautions would not be possible under the censorship of the national authorities.

In order to secure equal advantages, the responsibility of quarantine administration should be shared by countries bound together by trade-relations. Private interests, those of the shipowners,

and public interests, those of the community and State, being allied in seeking the advantages of strict sanitary administration, it is incumbent on governments, in view of their national interests, to exercise the authority, under international agreements, of regulating the sanitary management of the merchant marine in port and on the high seas, and all that pertains to quarantine. Mutual protection of health and commerce can only be assured by reciprocal agreement and concert of action. Coöperation is to be effected on a basis of mutual advantage by international agreement on a code of sanitary and quarantine rules and regulations founded on established general principles universally applicable, and adapted to the peculiarities of the service. These regulations should be applicable to commercial ports and to vessels upon the high seas. There should be a guarantee of reliable administration of the health-laws of every port, and a trustworthy certification of the exact state of health. There should also be required a reliable certification of the health of the crew and passengers and of the good sanitary condition of the vessel and cargo, before leaving port. Vessels of the larger size, especially those carrying emigrants, should be under the skilled and rigid sanitary supervision of officers permanently attached thereto, and the smaller craft under the supervision of deputized officers, who shall act under an approved code of regulations. Accurate daily records of the health of the vessel while at sea should be kept, and an attested copy be prepared for the advice of officials at the port of entry. The enforcement of these measures will, by preventing and restricting disease, aid in lessening the burdens of quarantine, and inure to the advantage of the health and commerce of the nations.

Under vigilant supervision it is hardly possible for vessels to become infected, but nevertheless cases of infectious disease will occur on shipboard, which will subject the vessel to treatment at the quarantine station. Under modern practice, detention is not required for a longer time than is necessary to form a certain judgment of the health of the vessel, and in certain cases for discharging the cargo, removing the passengers, etc., and disinfecting the vessel and its contents. It may be necessary to remove the passengers and crew for the purpose of observation, and hence every station should be provided with accommodations for the greatest possible demand for properly caring for passengers during observation. This is one of the greatest defects in local quarantines at the present day, but under national control this difficulty can be easily avoided. The facilities for the varied application of perfect disinfection must exist, otherwise quarantine is robbed of its main dependence.

The advantages of establishing quarantine under government control, broadened by international compacts, are: uniformity of system; general application, even to vessels on the high seas; efficiency of personnel, from life-duty and experience; concentration of apparatus and force at any port in emergencies; full sanitary reports of the ports of the world and advance knowledge of the condition and movements of vessels; avoidance of local prejudice and discrimination; economy of administration; uniform system of quarantine charges and fees; freedom in selecting the most eligible sites for quarantine stations irrespective of State jurisdictions; facilities for collecting valuable data; and the systematic and progressive study of contagious and pestilential diseases, and the establishment of confidence in the reliability of the service and the consequent avoidance of needless panic.

As a preliminary to negotiations for an international system it is absolutely necessary to establish a national service that shall have exclusive control of the quarantines of the country. Under such a system the present quarantine practices could be simplified, harmonized, and systematized as preparatory to entering into treaties with other nations for reciprocal advantages.

The attention of the coming meeting of the Pan-American Medical Congress should be directed toward the ends spoken of in the foregoing remarks. An excellent opportunity will be presented for establishing uniformity, encouraging coöperation, and formulating the desired regulations of an ideal international quarantine service.

SCLEROSIS OF THE NERVOUS SYSTEM.

THE pathology of the scleroses of the nervous system is not perfectly understood. The lesions are, as a rule, readily recognizable post-mortem, and during life the symptoms are generally fairly distinctive. It is, however, not a settled question whether what is called sclerosis is always the result of a single process, or is the terminal stage of many different primary conditions. We are not in a position always to indicate the primary process; and, again, it is difficult to make a distinction between

inflammation and degeneration. While the distinction is, perhaps, a refined one, the view has been expressed that the systemic scleroses—posterior, antero-lateral, descending and ascending—are dependent upon degeneration of axis-cylinders, followed by a conservative substitution of connective tissue; while cerebro-spinal, disseminated, or multiple sclerosis is considered as a hyperplasia of the connective tissue of tracts of various distribution, followed by secondary degeneration of the nerve-fibers. Whatever the sequence, the ultimate result is much the same. It can be safely accepted that in both instances we have to do with a chronic inflammatory process.

There is abundant reason to believe that there is the closest relationship between the various forms of nervous degeneration known as sclerosis, although the explanation why certain systems are so often alone affected is beyond our knowledge. On the other hand, it must be conceded that there are many cases in which the symptoms do not correspond to those of a simple systemic affection, limited to a single tract of fibers, but are those of lesions of irregular distribution, and post-mortem investigation has frequently verified the conclusions of clinical study. As accepted types of such mixed forms we have multiple sclerosis, ataxic paraplegia, and Friedreich's ataxia, or hereditary ataxic paraplegia. In the last two the lesion is practically the same—a sclerosis of the posterior and lateral columns—and the clinical differences are too slight that much stress should be laid upon them. The matter of hereditary transmission is not always easy of determination, and at best is only indicative of the transmission of a tendency to altered nutrition, a heightened susceptibility to abnormal processes. In a given case, it may be impossible to intelligently separate the one from the other. This brings us, too, to the close clinical resemblance between multiple sclerosis and paralysis agitans. There are apparently border-line cases that can be placed in either category, and a few cases have been recorded in which, during life, the symptoms of the one condition predominated, while the lesions of the other were found post-mortem. It is on account of these close resemblances, and the intimate interweaving of the two affections, that we feel justified in considering paralysis agitans as a form of diffuse cerebro-spinal sclerosis.

Recently, attention has been called to a group of cases in which the symptoms conform to none of the previously recognized types, and in which lesions of irregular distribution have been found. To these cases the designation combined sclerosis has been applied. It is not rare to have added to the symptoms of a systemic sclerosis manifestations of involvement of another system of fibers. It is also a perfectly well known fact that inflammation of the peripheral nerves is often associated with posterior spinal sclerosis, while the association of posterior sclerosis and general paralysis of the insane is a matter of clinical record.

RAYMOND (*La Médecine Moderne*, 1892, No. 15, p. 276) has reported a case of combined sclerosis, in which symptoms of involvement of the posterior columns predominated. Subsequently, symptoms of paretic dementia were added, and a fatal termination was not long deferred. When an autopsy was held, a diffuse sclerosis of the cord was found, with especial involvement of the posterior and lateral columns, and interstitial inflammation of the cerebral convolutions.

THE GRADUATION FEE.

DOUBTLESS the wrestlings of our medical colleges with financial problems are already sufficiently severe without criticism of any of the established sources or methods of income. But doubtless, also, the graduation fee is indefensible on grounds of justice. After a student has paid his tuition fees for three or four years, fulfilled his duties, passed his examinations, and in every way complied with the regulations and legitimate demands of his *alma mater*, the likelihood of his thinking the *mater* decidedly *dura* will be increased by her demand for $30 or $40 before she will certify to the fact of his completed course of study. It may be said that the "sheepskin" itself and printing (or its illumination in the highest style of Spencerian art), costs a certain sum, and that the rental of the public hall in which the exercises are held, together with sundry other expenses—the Faculty banquet, for example—altogether make up a considerable item of expense for the institution, or, as the case may be, for the members of the Faculty.

In answer it may be protested that the parchment, with whatsoever chirographic skill illustrated, costs but a dollar or two; that often the public hall is charged to the graduates—as indeed it should be, but not if in addition to the graduation fee; and lastly,

that if the Faculty banquet is a matter of money it is not one of generous good-will and good-bye.

There is a certain amount of hugger-mugger about all this custom. What legitimate excuse can be offered for it? The great majority of medical students finds this unjustifiable demand hard enough to meet; but it is the custom; the students secretly feel its injustice, and they pay the fee and go away feeling less kindly to the college than they should.

Would it not be better to put the tuition fees properly high, let every charge rest upon a real excuse and reason, charge for diplomas and the public hall at cost, and not as at present from 100 or 200 hard-pressed and unwilling men extract $2000 or $6000 for reasons that will not bear frank discussion?

SOCIETY PROCEEDINGS.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting, April 27, 1892.

Vice-President CHARLES H. THOMAS in the chair.

DR. SOLOMON SOLIS-COHEN read a paper entitled, "Shall Physicians become Sales-agents for Patent Medicines?"

Section 4 of Article I of the By-laws of the Philadelphia County Medical Society reads as follows:

"Any physician who shall procure a patent for any instrument of surgery, or who sells or deals in patented remedies or nostrums, or who shall give a certificate in favor of a patented or proprietary remedy or patented instrument, or who shall enter into an agreement with an apothecary to receive pecuniary compensation or patronage for sending his prescriptions to that apothecary, shall be disqualified from becoming or remaining a member."

Article VIII of the By-laws of the Philadelphia County Medical Society accepts as an integral portion of those by-laws the Code of Ethics of the American Medical Association.

A section of that code of ethics treats "Of the Duties of Physicians to Each Other and to the Profession at Large." Article 1 of that section sets forth "Duties for the Support of Professional Character." Section 3 thereof condemns open or underhand advertising as "derogatory to the dignity of the profession." "These," it says, "are the ordinary practices of empirics, and are highly reprehensible in a regular physician." Section 4 continues:

"Equally derogatory to professional character is it for a physician to hold a patent for any surgical instrument or medicine, or to dispense a secret *nostrum*, whether it be the composition or exclusive property of himself or of others. For if such nostrum be of real efficacy, any concealment regarding it is inconsistent with beneficence and professional liberality, and if mystery alone give it value and importance, such craft implies either disgraceful ignorance or fraudulent avarice. It is also reprehensible for physicians to give certificates attesting the efficacy of patent or secret medicines, or in any way to promote the use of them."

To the clearness and force of this dictum nothing can be added. Its wisdom and its justice are beyond dispute.

It is unfortunately true that much of our therapeutics is as yet empirical. Nevertheless the best endeavors of the true physician are directed toward establishing a rational basis for that which experience has proved to be beneficial; toward obtaining scientific data by which to make progress to a therapeutics not empirical; and toward eliminating from the traditional heritage of the profession such measures as may have had their origin in superstition or mistaken observation. To use preparations of unknown composition; to use mixtures of innumerable substances, some directly opposed to each other; to use even rational and known combinations of which the ingredients and proportions have not been adjusted to the indications and conditions of the individual case—are certainly not scientific methods or practices likely to advance rational therapeutics.

That much of the flavor of the mystery and witchcraft that at one time appertained to the practice of the healing art should have survived among the vulgar is only a phenomenon to have been expected in the natural course of social evolution. Hence it is that homeopathy and mind-cure and patent medicines have so powerful and so profitable a hold upon the purses of the community, and this not alone among the ignorant and the unlettered. It is a notorious fact that members of the clergy—presumably educated and intelligent men—are among the most prominent and persistent givers of testimonials to the virtues of advertised nostrums, and medical men and medical journals have long made the religious press a target for satire and invective, because of the hold that the advertising quack has secured upon its columns.

In an address to the Medical Society of the State of Pennsylvania at its last meeting, in calling attention to the alliance between the secular press and the empirics and nostrum-venders, I felt justified in saying that the publishers of magazines and newspapers that allowed themselves to advertise the curative virtues of this or that ready-made preparation or alleged remedial measure, to be applied indiscriminatingly to all cases—whether of one disease or of many diseases—were accessories to a crime against the unfortunate and the helpless; not alone because of the money filched from the pockets of those deluded by the false promises held out to them; not alone because of suffering unrelieved and lives deprived of their chance for prolongation; but in many instances because of the disease and suffering and death directly produced by the poisonous compounds or noxious gases administered to any that chose to purchase. If such criticism was justified—and who is here that will deny its truth?—if such criticism was justified when applied to those who make no pretence of special knowledge or of devotion to a noble art—to those whose object is solely and avowedly commercial—what language remains to characterize the action of medical journals that permit the insertion in their columns of advertisements such as these that I pass around? What severity of reprobation is adequate for

the conduct of the *Journal of the American Medical Association?* What words of condemnation are strong enough for the physician that permits his name to be associated with these devices of the devil?

The frankly unscrupulous patent-medicine vender, the maker of "Safe-cures," or "Temperance Bitters," or "Sure Specifics," is at least to be commended for what, to paraphrase a remark of Senator Benjamin Harrison's, may be termed his "bold brutality." His allegations of philanthropic motives are not intended to be believed; they deceive no one—they are the recognized *ad captandum* devices of the clever advertiser—and, in the sale of his wares, there is no pretence of examination, or of diagnosis, or of prescription based on diagnosis.

Far more iniquitous and far more dangerous to society is the wily manufacturer that advertises "to the profession only." Whether he ostentatiously holds secret the composition of his nostrum, or whether with pretended frankness he describes it with an appellative that means nothing, or publishes a formula that cannot be carried out, his object is the same; he seeks to make the physician's the hand whereby he may reach pockets shut from the coarser methods of the Warners, the Pinkhams, and the Jaynes; for, after all, it is the minority that can be deluded by the flaring posters of "Wizard Oil," or the lying testimonials of "Tonic Vermifuge." When a sick man applies to a physician, thinking that thereby he will secure the benefit of special knowledge brought to bear upon the conditions of the individual case, entrusting to the conscience of his medical adviser his health and his life, he is entitled to the skill and the thought for which he pays, and which he deems himself to be receiving. He certainly deserves better treatment than to be handed over to the mercies of "antikamnia," or "febricide," or "quickine," or "gleditschine," or "Freligh's tablets," or "Listerine," or any other of the unholy crew. If such is to be his fate, let him have the satisfaction of buying the worthless or poisonous stuff directly, without the sham of a professional consultation, and without paying a purchaser's commission to the medical sales-agent.

At the coming meeting of the State Society I purpose offering the following resolutions, for which I ask the support of this Society:

Resolved, That the Medical Society of the State of Pennsylvania hereby expresses its highest disapprobation of the practice of giving certificates or testimonials to secret preparations alleged to be of medicinal virtue, and calls the attention of the affiliated County societies to the fact that such action on the part of members of the said societies is in derogation of the dignity of the profession, and in violation of the letter and the spirit of the Code of Ethics of the American Medical Association and of this Society.

Resolved, That this Society likewise expresses its disapprobation of the practice of inserting advertisements of secret preparations in the columns of medical journals, such action being an insult to the intelligence of the profession, and a degradation of journals indulging therein to the level of the patent-medicine almanac. Especially to be condemned is the action of the *Journal of the American Medical Association* in admitting such advertisements.

Resolved, That copies of these resolutions, duly attested by the permanent Secretary, be sent to all County societies in affiliation with this Society, to the American Medical Association, to State medical societies in affiliation therewith, and to the publishers and editors of American medical journals.

On motion of Dr. J. MADISON TAYLOR, the resolutions were adopted as the sense of the Philadelphia County Medical Society, and the delegates to the Medical Society of Pennsylvania were instructed to officially present and support them.

DR. T. RIDGWAY BARKER read a paper entitled "Does Organic Disease of the Heart Preclude the Use of Chloroform in Parturition?"

In entering upon the discussion of a subject of such paramount importance to mother, offspring, and obstetrician, one cannot lay too much stress at the very outset upon the axiom that "A good remedy will fail of its effect if not properly administered." This fact must be kept uppermost in our minds if we would avoid fatal results, not due, however, to the employment of the agent, as some would make it appear, but to the lack of attention and care exercised in its administration. That there is a radical difference between surgical and obstetric anesthesia (analgesia) goes without saying. If we consider for a moment the stages of anesthesia, which differ only in the profoundness of the impression—first, sopor; second, stupor; and, third, stertor—we cannot fail to observe that in analgesia one rarely has occasion to carry the effect beyond the first degree (sopor), while in surgical anesthesia we are obliged to advance beyond this and keep the patient in the second stage, or that of stupor, thus decidedly increasing the gravity of the prognosis.

In this connection, let us devote a moment's consideration to the progressive effect of chloroform-vapor upon the nerve-centers of the cerebro-spinal system, beginning, as it does, at the inferior extremity of the cord, sacro-lumbar, and gradually extending its paralyzing influence upward until it reaches and expends its force upon the medulla oblongata. These well-established clinical observations having been verified by physiologic experiment, we are justified in putting them to practical application. What other agent, may be pertinently asked, can relieve—aye, abolish—pain so quickly and safely, yet leave reflex muscular contractility unimpaired, as chloroform? Ether and ethyl bromide have found favor with some practitioners, but neither can displace chloroform.

Fordyce Barker states in his writings: "I may say here that I have long regarded chloroform as the best and safest anesthetic in obstetrics, and that since 1850 I have used no other."

The danger from the employment of chloroform in obstetric practice depends more upon the carelessness with which it is administered than to any toxic effect inherent in it. The four cardinal points to be borne in mind in its administration are: First, the admission of plenty of pure atmospheric air; second, the liberation of a small volume of the vapor at a time; third, attention to the respiration; and, fourth, frequent observations as to the force and frequency of cardiac action. That in the recorded cases death has been due in a great measure to saturation of the residual air in the lungs to

a fatal degree can scarcely be doubted. A few deep, forced inspiratory efforts will quickly produce such a condition. Withdrawal of the agent under these circumstances cannot prevent the further entrance of the chloroform-vapor into the circulation, for it already fills the air-cells. Nor will attempts at artificial respiration prove effectual, since but a small quantity of the residual air can be forced out of the lungs, while that which enters fails to sufficiently dilute the vapor owing to the tardiness of diffusion.

Let us not suppose, however, that because we administer to the parturient female small quantities of the drug continuously, no risk is therefore incurred, for experiments directed to solve this important question go to prove that even small doses, when continuously inhaled, tend to produce dangerous, and at times fatal, cardiac exhaustion. Far different is the result when the vapor is given intermittently, as is the unalterable rule in obstetrics. Should we seek authority for the statement that the dangers from the careful administration of chloroform in labor are too insignificant to warrant its refusal, we have only to turn to the *American System of Obstetrics* to find therein the following: "The danger when chloroform is used only to the extent of mitigating or abolishing pain in childbirth is practically *nil*." Lusk, quoting from Bert's experiments, states "that chloroform might be intermittently administered for an indefinite period with safety." These remarks do not apply to its use in the third stage of labor, for, as is well known, after delivery of the child it is likely to occasion relaxation of the uterus, thus favoring post-partum hemorrhage.

Offering the foregoing as a preface to my remarks on the judiciousness of employing chloroform when the parturient female suffers from organic cardiac disease, it now remains for us to consider the effect of parturition upon this enfeebled circulatory organ, thereby securing a scientific basis for our conclusions. In the first stage of labor, we find the muscular contractions confined to the uterine muscular layers and directed toward neutralizing the action of the circular fibers of the cervix, while in the second or propulsive stage not only does the uterus exert its power to the utmost, but also the abdominal and respiratory muscles are brought into action by the will of the parturient in her efforts to expel the fetus. The diaphragm is forced down and its movements paralyzed by the woman holding her breath.

The other respiratory muscles are likewise unable to act, and hence imperfect oxidation of the blood results. As a consequence, the cardiac movements are accelerated, greater resistance is met with in the pulmonary and aortic circulations. Moreover, a tendency exists to venous congestion, as evinced by the hue of the face and the swollen veins.

Owing to the excruciating pain experienced when the head passes through the cervix, the parturient is further tempted to make additional muscular efforts, which only augment the difficulty. Under normal conditions, this strain is of such brevity that it cannot be considered of any importance, but when complicated by disease of the heart is of far greater gravity. If the condition be one of fatty degeneration due to a previous pericarditis or myocarditis, resulting in faulty nutrition and enfeeblement of the heart's action, as evinced by weak impulse, venous stasis, confused and irregular sounds, anemia alike of brain and of other organs, with faintness and oppression on the slightest exertion, this interference with circulation and respiration may readily tax the powers of the heart too far, and so cause speedy death from paralysis. Here the conditions that pertain in surgical anesthesia are absent. The indications present are to allay excessive muscular action and respiratory spasm, which are threatening the over-stimulated heart.

To allow the woman to continue such efforts is to permit her to commit suicide; to warn her to desist when in such agony is useless; while delay is likely to be fatal. How can we overcome this condition of nervous excitement? Can we accomplish it by the administration of chloroform? Yes; of the two evils, for we must acknowledge that there is an element of risk in giving chloroform, we can only choose the lesser, and so promptly proceed by inhalation to relieve the accessory muscles of parturition of their strain. By the abolishment of pain we lessen the work required of the laboring heart, which, instead of beating at the rate of one hundred and forty or more a minute, may diminish in frequency to ninety or one hundred.

What has been said of fatty heart is equally applicable to conditions of hypertrophy and dilatation.

The equilibrium, if disturbed, is almost certain to result disastrously. If relief is not afforded, the sense of fulness in chest and the oppression due to bronchial congestion become most distressing. The cyanosis (from deficient aëration) is greatly exaggerated, while the insufficient blood-supply to the brain causes syncope and may be succeeded by coma, if the excessive reflex disturbance be not removed. Nor are the indications for the administration of chloroform materially different in the case of females in labor with valvular disease. Whether it be mitral in the young adult or aortic in the aged primipara, the cardiac strain must be relieved if we would save our patient. As is well known, all forms of valvular disease ultimately develop a condition of ischemia on one side with corresponding low tension, while on the other side is stasis with high tension. While, by compensation, life may run on for years, yet, when the strain of parturition comes, it will soon be overthrown if precautions are not taken to prevent it.

Of what benefit will be our knowledge of the value of cardiac "physiological rest," as laid down by Fothergill, if we do not apply it under these conditions? We all appreciate the importance of securing "quietude of mind and body" when such pathologic states exist. Then why not employ the quickest and safest means to obtain it by the inhalation of chloroform? If the danger is great from "active exercise—climbing mountains, running up stairs, lifting heavy bodies, and all kinds of exercise involving heart strain"—how much greater, aye, how immeasurably so must it be when the parturient woman forces, with the anguish of despair, every muscle to its utmost in her desire to deliver her child.

From a study of chloroform-anesthesia in obstetric practice, we have seen how the agent should be administered and how it acts. Surely none will contend that in its employment under these circumstances we act otherwise than for the best interest and safety of our patient. That one may not be charged with being a blind adherent to theory, one has only to turn for support and justification

to the teachings of the late lamented Fordyce Barker, who states: "It seems to be almost accepted as an axiom, with both the profession and public, that the inhalation of chloroform is dangerous for any woman with disease of the heart. For more than thirty years I have been convinced that this opinion is quite erroneous, and I have so taught in my lectures and in former writings." He goes on further to say: "I have seen several cases, complicated by dangerous heart-lesions, that terminated favorably, as I think, solely from the use of chloroform."

Snow, likewise, is of this opinion. "In all forms of valvular disease," he says, "chloroform, when carefully administered, causes less disturbance of the heart and circulation than does severe pain." To quote from Championnière: "If," he says, "I recognized an organic affection of the heart, without pulmonary complications, I should rather give the woman chloroform than to let her suffer." Were further proof necessary as to the propriety of employing chloroform-anesthesia, one might include among this group of clinical observers, Vergeley, who expresses himself thus: "Diseases of the heart are not a contra-indication to the use of anesthesia." Macdonald states: "In almost all cases of heart-disease with labor, chloroform has been given, and apparently with benefit, during delivery. If carefully administered, I think it cannot but be useful in all cases." Since such eminent authorities advocate its employment, can we justify ourselves in refusing our patients the benefit and comfort that this agent affords? What is the danger from chloroform compared to the state of exhaustion and collapse into which the parturient woman will inevitably fall? If this heart is forced to the verge of paralysis from overwork and excitement, why shall we not use the means at our command to lessen that strain? Let us have a reason for the faith that is in us, and not hesitate to fearlessly employ extreme measures to overcome extreme dangers.

Chloroform by inhalation can and will, if properly administered, save the lives of parturient women suffering from organic disease, when death seems imminent from over-stimulation of its ganglia through reflex nervous action. Organic heart-disease, then, does not preclude the use of chloroform in labor, but rather is a condition calling for its careful administration.

NEWS ITEMS.

The "Bichloride of Gold" Delusion.—The following preamble and resolution were adopted at a recent meeting of the Hampden (Massachusetts) District Medical Society:

Whereas, according to common and newspaper report, and upon information and belief, it is known that a member of this Society and fellow of the Massachusetts Medical Society in regular standing, has, by associating himself with one of the most notorious impostors of this century, in the application and use of a remedy for the cure of inebriety, called "bichloride of gold," and whose exact composition it is pretended is known only by, and is the sole property of, a certain individual; and

Whereas, no such stable chemical combination is possible, and the substance actually used with so much secrecy and profit to the proprietor is and has been employed in suitable cases for years by regular physicians, who well know its limitations and dangers; and

Whereas, by associating himself with a regular physician this pretender hopes to gain prestige and the quasi-indorsement of the regular profession, thus enabling him longer to delude the public; and

Whereas, the association of a regular physician in such a capacity is calculated to injure the public and is degrading to those who are in fellowship with such a physician, and recognizing that "naught but evil can finally result from trifling with moral or physical facts, and that it is better to cure rightly and really than wrongly and delusively," and that by the "humbuggery of secrecy, delusion, and hypnotic suggestion," a far less number will, in the end, receive benefit; and

Whereas, it is the opinion of the members of this Society that the use of the drugs, in the manner employed, for the cure of inebriety by the aforesaid impostor, produces a cerebral stimulation, with intellectual disorders which are sometimes quite serious, together with other grave nervous troubles, themselves constituting a form of inebriety frequently leading to insanity and suicide, and a lowering of vitality, rendering the patient less able to resist and recover from ordinary diseases; and

Whereas, in those cases of inebriety claimed to have been cured by means of this pretended secret method of treatment, it is our opinion that such cures resulted not *because* of said treatment, but *in spite* of it, and there seems little doubt that hypnotic suggestion played an important part in effecting said cures, and it is our opinion that in all of the so-called "cures" the result attained could have been better secured by improving the moral condition of the patient, by the use of tonics or hydro-therapeutics, regulating nervous action, and by attention to the digestive tract, without subjecting the patient to the dangers of another form of inebriety, and without the element of secrecy. It is, therefore,

Resolved, That this Society hereby directs its President to refer this subject to a proper committee who shall, before the next regular meeting, ascertain if any member of this Society has identified himself with the manufacture, sale, distribution, or use of any secret remedy, contrary to the Code of Ethics under which this Society is organized, and if so, that such member or members be recommended for expulsion from membership in this Society at said next regular meeting.

College of Physicians; Presentation of Portraits.—A banquet was given by the College of Physicians of Philadelphia on Saturday, April 30th, on the conclusion of which each member drank from the loving-cup to the memory of the late D. Hayes Agnew. Dr. Horatio C. Wood, on behalf of the medical profession of Philadelphia, formally presented to the College a fine portrait of Dr. Alfred Stillé, a former president of the College. The portrait was received by the President, Dr. S. Weir Mitchell. Dr. Mitchell, on his own behalf, presented a portrait of Dr. Oliver Wendell Holmes, accompanying the presentation with a poem. Dr. J. K. Mitchell read a reply in verse sent by Dr. Holmes, who was unable to be present. The portrait was received by the Vice-

President, Dr. J. M. DaCosta, who paid an eloquent tribute to the original of the portrait and to the donor. The exercises also included an address by Dr. J. W. Holland, on the "College"; one by Dr. William H. Welch, of Baltimore, on "Associate Fellows," and one by Mr. Talcott Williams, on "The Patient."

The Association of American Physicians.—In addition to the papers already announced for the meeting of May 24th, 25th, and 26th, the following will also be presented:

"The Treatment of Experimental Tuberculosis by Koch's Tuberculin, Hunter's Modifications, and Other Products of the Tubercle-bacilli," by E. L. Trudeau, of Saranac Lake; "A Case showing Symptoms of Landry's Paralysis—Recovery," by A. McPhedran, of Toronto; "The Areas of Anesthesia in Spinal-cord Lesions as a Guide to Localization," by M. A. Starr, of New York; "The Different Forms of Cardiac Pain," by Samuel G. Chew, of Baltimore; "The Late Systolic Murmur," by J. P. Crozer Griffith, of Philadelphia; "Influenza and Some of Its Present Aspects," by Morris Longstreth, of Philadelphia.

A Medical Organization for Social Purposes.—It is proposed to establish a club for social purposes, restricted in its membership to members in good standing in the *Regular Profession* of Medicine in Philadelphia. A modest club-house is to be secured in a central location, to be fitted up with chess-tables, billiard-tables, etc., where meetings can be held, committees have accommodations, and members may congregate for social intercourse. A reading-room is to be opened where may be kept on file the principal medical journals, the literary magazines and journals of the day. It is contemplated to have occasional (monthly or bi-monthly) dinners, to which non-members of eminence may be invited. The fees and dues are to be moderate, ten dollars initiation at present, and annual dues of ten dollars.

Those who may feel interested in the formation of such an association, and who may wish to be present at a general meeting for the purpose of organization, are invited to communicate at an early day with Dr. Lemuel J. Deal, 2119 Howard Street.

The Fourth International Congress for the Study of the Abuse of Alcohol will be opened on September 8, 1892, at The Hague. The following subjects will be discussed: Alcoholism from a moral, hygienic, and medical point of view; The preventive and educational means employed to correct the abuse of spirituous liquors (societies, meetings, the press, popular entertainments); The coercive means available by the State and the community to overcome drunkenness.

Philip Biedert has been elected Professor of Pediatrics at the University of Innsbruck.

Carl Guenther has been appointed an assistant in the Hygienic Institute at Berlin.

The Third International Congress for Criminal Anthropology will be held at Brussels from August 7th to 14th.

Germain-See has withdrawn from the editorial management of *La Mèdecine Moderne.*

BOOKS AND PAMPHLETS RECEIVED.

Reports of the Trustees and Superintendent of the Butler Hospital for the Insane. Providence: The Press, 1892.

Some of the Influences Which Affect the Power of the Voluntary Muscular Contractions. By Warren P. Lombard, M.D. Reprint, 1892.

Intra-thoracic Surgery. By DeForest Willard, M.D., Ph.D. Reprint, 1892.

The Second Year's Work in Diseases of the Rectum at the New York Post-Graduate Hospital. By Charles B. Kelsey, M.D. Reprint, 1892.

Systemic Infection from Gonorrhea. By Bedford Brown, M.D. Reprint, 1892.

A System of Gynecology. Based upon a Translation from the French of Samuel Pozzi. Revised by Curtis M. Beebe, M.D. With 359 Illustrations. New York: J. B. Flint & Co., 1892.

Outlines of Zoölogy. By J. Arthur Thomson, M.A., F.R.S.E. Illustrated. New York: D. Appleton & Co., 1892.

Transactions of the American Orthopedic Association, Fifth Session, held at Washington, D. C. Vol. IV. Philadelphia: Published by the Association, 1891.

Diseases of the Eye. A Handbook of Ophthalmic Practice for Students and Practitioners. By G. E. de Schweinitz, M.D. With 216 Illustrations and 2 Chromo-lithographic Plates. Philadelphia: W. B. Saunders, 1892.

Enlarged Tonsils, and Their Harmful Effect on Health and Development. By William T. Cathell, M.D. Reprint, 1891.

The Teachings of Experience and of a Rational Therapeutics as to the Treatment of Pneumonia. By Boardman Reed, M.D. Reprint, 1892.

A Treatise on Medical and Surgical Gynecology. By S. Pozzi, M.D. Translated from the French edition, with Additions by Brooks H. Wells, M.D. Vol. II. With 174 wood-engravings, and 9 full-page plates in colors. New York: William Wood & Co., 1892.

A Junior Course of Practical Zoölogy. By A. Milnes Marshall, M.D., D.Sc., M.A., F.R.S. Assisted by C. Herbert Hurst, Ph.D. Third Edition. London: Smith, Elder & Co., 1892.

Transactions of the American Pediatric Society, Third Session, held in Washington, D. C., September 22 to 25, 1891. Edited by William Perry Watson, A.M., M.D., Recorder. Vol. III. Printed by Fairchild & Co., 1892,

A Text-book of the Practice of Medicine. For the Use of Students and Practitioners. By R. C. M. Page, M.D. New York: William Wood & Co., 1892.

Text-book of the Eruptive and Continued Fevers. By John William Moore, B.A., M.D., M.Ch. Univ. Dubl. New York: William Wood & Co., 1892.

Diseases of the Nervous System. By Jerome K. Bauduy, M.D., LL.D. Second Edition. Philadelphia: J. B. Lippincott Co., 1892.

Lectures on General Etiology, Delivered at the Chicago Medical College. By H. Gradle, M.D. Pamphlet. Chicago: W. T. Keener, 1892.

Intestinal Anastomosis and Suturing. By Robert Abbe, M.D. Reprint, 1892.

A Contribution to the Study of Headaches. By Joseph Collins, M.D. Reprint, 1892.

Cases of Gall-bladder Surgery. By Robert Abbe, M.D. Reprint, 1892.

THE PRESENT STATUS AND CLAIMS OF ELECTRICITY IN GYNECOLOGY.

BY G. BETTON MASSEY, M.D.,
OF PHILADELPHIA.

TRIPIER, of France, the father of electro-therapy in the diseases of women, writing first in 1859, initiated a movement that failed to attract the attention of the profession until the genius, patience, and perseverance of his pupil, Apostoli, imperatively commanded an audience. Making his first contributions upon the subject in 1881, the latter soon extended the claims of his teacher beyond the value of faradic currents in the puerperal condition and in displacements, and promulgated that series of essays on his method of treating fibroid tumors of the uterus that soon made it a familiar subject throughout the scientific world. The first of these communications was made in 1884, and was soon followed by corroborative reports from other observers in many lands and in many languages; but it was followed also, as a natural consequence, by fierce attacks from the surgeons who had but just begun those bloody experiments that have not yet overthrown the earlier dictum enjoining the non-removal of these growths.

The controversy thus provoked became warm, but lost much of its fervor when distinguished English surgeons—such as the Keiths and Sir Spencer Wells—ranged themselves on the side of the electro-therapeutists. The method could not fail to be largely adopted when advocated by such an one as the elder Keith, who himself possesses a still unrivalled record in the surgical removal of fibroid tumors. Hastily adopted by many gynecologists, some of whom were profoundly ignorant of the most rudimentary knowledge of the proper mode of handling so subtle an agent as electric force, the progress of the remedy in this affection has yet steadily advanced toward the realm of fixed facts, enshrined in a bewildering abundance of contributions to the journals. In America alone the stimulus thus given to the electric treatment of fibroids and other affections of women has already resulted in the production of four treatises in book form,[1] besides a lengthy contribution to the American Gynecological Society.[1]

There is, I believe, no exception to the rule that all those observers who were competent to make an intelligent study of the uses of electricity in gynecology have arrived at conclusions that point to its great value, and not a few of them look upon the methods as yet in the infancy of a most useful life. An intelligent comprehension of the future of methods possessed of such apparent possibilities—methods that admit of direct penetration to diseased tissues and the convergence therein of many known and many yet unknown remedial agencies—cannot do otherwise than compare them with the recent triumphs of electricity in the arts and industries. May not this future progress of medical and surgical electricity be phenomenal also? But a hundredth part of this pace would revolutionize both medicine and surgery, already enriched by these newly discovered powers of hitherto unheard-of strong currents and the less known cataphoric actions by which useful drugs may be carried through the skin and tissues to actual seats of disease.

Confining attention to existing knowledge of the subject, a brief outline may be given of the present status of electro-therapeutics in gynecology, in the shape of a collection of opinions such as the writer is compelled to send daily to inquiring physicians whose engrossing work in other directions is more than ample excuse for a lack of familiarity with the latest details and results in this field of special practice.

Fibroid tumors. In the writer's personal experience, six of these growths have disappeared by absorption under electric treatment. One of these was as large as an adult head, extending above the umbilicus, the bulk of the remainder being much smaller. Of the other cases, about 92 per cent. were arrested and reduced in size in varying degrees, a symptomatic cure, in the removal of pain, hemorrhage, etc., being practically invariable. About 8 per cent. were unsuitable for this mode of treatment.

The cases best suited for the method are those that present nodular, interstitial growths of all sizes

and in which the uterine cavity is involved and enlarged. Hemorrhagic complications probably favor ultimate decrease and disappearance, these complications themselves being readily removed. The unfavorable cases are those in which the growths are subperitoneal and but slightly connected with the uterus; the tumor being too far removed from the cervical portal of treatment. When very large, they may be reached by puncture through the abdominal wall. The edematous and soft myomata are unsuited to the ordinary mode of applying strong currents, but may be helped and at times greatly reduced by patient percutaneous treatment, while the degenerating fibro-cystic variety is still regarded by many as contra-indicating electric treatment.

Chronic metritis and subinvolution. Catarrhal and inflammatory affections of the uterus, so often the initial points of ovarian and tubal disease and malignant growths, offer probably the most important field for electricity in gynecology. As a topical application to the uterine cavity, electricity is possessed of many advantages, with which are associated even more important contractile and sorbefacient actions, increasing the tone of the relaxed and congested muscular tissue and promoting metabolic changes in the older cases characterized by sclerosis. Avoiding the dangers and discomforts of other less effective remedies, such as the application of acids and of iodine, and the curetting operation, electricity does not accomplish results by harshly destroying the mucous membrane, but by a stimulation of cell-activity in all the affected tissues, the influence on the neuro-muscular elements being unique. In those instances in which the affection is no longer restricted to local lesions, but involves the nervous system and the general health, the local treatment should be supplemented by general tonic applications of electricity and massage. The association of nervous break-down and neurasthenia with this condition has been noted for many years, and it is only lately that its importance is in danger of being neglected in favor of views that relegate the mischief entirely to the nervous system. Having failed to cure their cases by scraping and by repairs of innocent tears of the cervix, many surgeons have begun to deny the importance of these catarrhal hypertrophies, placing their patients on the rest-treatment as a last resort. Catarrhal hypertrophies are productive of even more mischief within the uterus than within the nasal cavities, and it is only when associated with properly directed treatment to the original focus of disease that the rest-cure can remove the results of the local affection. A divorce of gynecologic from neurologic treatment in such cases is inimical to complete success. In my experience some cases of neurasthenic backache, associated with enlarged uterus, have yielded to single applications of the galvanic current within the uterus.

Another class of cases of chronic metritis is neglected because the surgeon's attention is directed exclusively to secondary affections of the tubes and ovaries, and the appendages are removed under the impression that they alone are diseased. In these cases a continuance, or even an increase, of the pain is the inevitable result of the operation until the true nature of the affection is recognized and proper treatment instituted.

In recent subinvolution of the uterus after childbirth the faradic current is usually sufficient, though coëxistent metritis will always require the conjoined employment of galvanic treatment for its topical action. The treatment of the later stages of subinvolution does not differ materially from that adapted to chronic metritis, though less time is usually required to accomplish a permanent cure.

Metrorrhagia. In post-partum hemorrhage strong faradic currents from the primary wire are instantaneous in causing contraction of the uterus, with cessation of the bleeding. The current is preferably applied by an aseptic, intra-uterine bipolar electrode, but in its absence any monopolar electrode that has been steeped in boiling water may be inserted and the circuit completed by a large abdominal pad. In hemorrhage more remote from the puerperium, including that due to retained decidual shreds, the faradic current becomes progressively less valuable than the galvanic, the cases of hemorrhagic endometritis and menorrhagia requiring the latter. Under the action of currents of from ten to seventy milliampères the fungous and granular surfaces of the endometrium are freshened and quickened and the smaller shreds detached and permitted to drain away, and thus the source of the troublesome dribbling corrected without harsh scraping. The positive pole, which is usually the best for this purpose, has the incidental advantage of being decidedly microbicidal when the current is strong, as ascertained experimentally by Apostoli and Laguerrière.[1]

Displacements. Nearly forty years ago the doctrine was advanced that flexions and versions of the uterus were not in themselves important, and gave rise to suffering only by reason of other conditions associated with them. This view, though early buried under an avalanche of pessaries and other mechanical supports devised under an opposite belief, has of late been revived by those that not only doubt the correctness of the principles involved in the use of pessaries, but are in a position to see the harm done by the pressure of these devices on inflamed and tender ovaries and

[1] Reprint from Répertoire de Police Sanitaire, Vétérinaire et d'Hygiène Publique. Paris, 1891.

the stretching of already weakened vaginal supports. The truth probably lies nearer the assertion of the secondary importance of the displacements in the majority of cases, though its demonstration in the past has been hampered by inadequate means for the cure of the associated conditions. Now that the metritis, endometritis, and perimetritis may be successfully combated by the restorative action of galvanic currents, the real harmlessness of many deviations in the position and shape of the uterus becomes manifest, though often the deviations themselves are lessened by the curative process. Lacking the causative congestions and inflammatory conditions, it is hard to see how they are as important as has been assumed, and, if so, how the placing of an unnatural skeleton in the vagina is to accomplish a cure rather than mere amelioration. Such artificial aids to regain a supposedly correct straightness cannot in any way compare with the natural muscular supports of the uterus, and when removed must leave these structures even more relaxed and weakened than they were before. Such relaxations of the vagina, due to atrophy of the muscular fibres of its walls, require toning and stimulation rather than further weakening by the distention of pessaries and tampons. It is an orthopedic question, and all experience with weakened muscles on the exterior of the body teaches us that apparatus is secondary to electricity, massage, and gymnastics. Either faradic or galvanic currents are most useful in restoring muscular force and vigor and retaining prolapsed uteri in normal position, unless by reason of deep tears of the vaginal muscles or of profound degeneration the organ is beyond other aid than that given by such devices or by surgery. When this toning is possible, important subsidiary results may follow in the lessening or removal of atonic dispareunia, which is often at the bottom of weakened conditions in both sexes.

Ovaritis, salpingitis, and peri-uterine inflammation. In these distressing conditions the recent doctrine has been taught that amputation of the ovaries is the only remedy. I shall not discuss the startling frequency of this mutilation of the body, or the increased pain rather than relief that results at times in non-fatal cases; but I wish to affirm that chronic inflammatory affections of the adnexa that are unaccompanied by abscess or cystic accumulation are almost invariably amenable to relief and cure by the interpolar action of the galvanic and faradic currents. The results are at times as striking as those that follow a similar percutaneous application to a sprained ankle, the engorgement, hyperplasia, and plastic exudates being dissipated and absorbed, and a case otherwise condemned to the uncertainties of an operation for castration restored to practical and permanent health. Some old adhesions will remain, it is true, as in an old pleurisy, but the active morbid condition from which the patient suffered will be cured. The most obstinate cases are not those in which ovarian and perimetric inflammation predominates, but the tubal cases; yet in these, also, continued treatment will often achieve complete restoration of health, without mutilation or the artificial production of conditions that normally occur in old age. Cases of simple ovaritis attended by ovarian congestion, cases of enlargement and of ovaralgia, are quickly amenable to treatment, the writer having notes of a number of such cases in which this treatment was successful when undertaken after a day had been set for operation.

Menorrhspasm and menorrhalgia. Personal observation of the curability of painful menstruation by the use of the galvanic current during the intermenstrual period led me to make a reëxamination of the prevalent views of the nature and causation of the affection several years ago, the results being reported to the Philadelphia Obstetrical Society. The conclusions arrived at were that what has been called obstructive dysmenorrhea is extremely rare, the supposed stenosis being a mere spasmodic contraction of the circular fibers of the internal os. The morbid element is not obstruction, but functional spasm, as already proved by Schultze, who showed that accumulations never existed. An even better proof may be obtained by subjecting a patient, while in the throes of the pain of menorrhspasm, to a simple abdomino-dorsal application of the galvanic current, by means of large electrodes, on one of which the patient reclines. If the current is turned on without shock until a strength of a hundred or a hundred and fifty milliampères is reached, the pain will usually be quelled for that period, and a freer flow is immediately obtained. If the pain and lack of flow were due to fibrous constriction, the current would intensify the pain rather than relieve it, for it would increase the force of the alleged "mimic labor," and could not, thus applied, relax a fibrous stricture. To accentuate this view of the pathology of the trouble the name menorrhspasm was proposed in place of dysmenorrhea, the latter having received too mechanic a meaning in the past. Symptomatically considered, it was but a menorrhalgia due to hyperesthesia of the uterus and adnexa, the attempt at functionation causing a painful neuro-muscular storm. Moderate galvanic currents by the vaginal or uterine method, in accordance with the condition of the endometrium, allay the causative hyperesthesia, stimulate undeveloped organs, and cure associated catarrhal tendencies. About two inter-menstrual periods constitute the usual time required.

Pelvic neuralgia. Persistent pain in the pelvic region, particularly in the neighborhood of the

ovaries, or radiating from the pelvis to the hips, back, and thighs, may be due to organic congestion and inflammation, to inflammation of the pelvic nerves, or to centric disease of the nervous system, an exact diagnosis being at times impossible. When due to congestion, as in youthful persons and in those with undeveloped organs, the faradic current of the fine wire is most efficient (as maintained by Tripier, Apostoli, and others), when associated with general electric treatment and massage. If inflammation is found, the methods detailed elsewhere should be employed and will usually be found effective.

The existence of inflammation of the cerebro-spinal nerves of the pelvis has received no attention so far from either writers or clinicians; yet undoubted cases have occurred in the writer's experience. In character of pain the affection much resembles sciatica, except that the situation is usually in the neighborhood of the ovaries or higher up. The sclerotic ovaries that have at times been ineffectually removed for the relief of this neuritis indicate one of its effects, and emphasize the neural origin of the trouble. In the treatment of this variety of pelvic pain the franklinic current has value at times, though resort must usually be had to the galvanic, as in sciatica and crural neuralgia. Some cases are of undoubted centric origin, and in these neither electricity nor removal of all of the contents of the pelvis piecemeal will avail anything in affording relief.

Neurasthenia and nervous prostration. In considering the place and importance of electricity in neurasthenia and nervous prostration, the writer should state that the first name, neurasthenia, is applied by him to those cases that, grossly speaking, are traceable to some internal or constitutional cause, while the term nervous prostration is reserved for the cases clearly occasioned primarily by an external stress, either mental or physical. The two conditions insensibly shade into each other; yet important practical differences are often noticeable. As to the nature of these multiform diseases and their causation it is, of course, true that neurasthenia in the female is frequently a reflex from the irritation of a metritis or ovaritis, and in such cases good results can only be obtained after cure of this initial point of disease. There are, nevertheless, many cases that are not associated with pelvic disease, and in these there can be no question of the correctness of the hypothesis of Beard that places much of the onus on the central nervous system itself; yet a still more remote and real cause is doubtless the auto-intoxication of the individual by vitiated secretions. Incapable of producing healthy products, by reason of lessened vigor in the nerve-centers, the secretory organs of the body, particularly those of the digestive and assimilative apparatus, permit re-absorption of poisonous ptomaïnes that, in the peculiar condition of the nervous system, reinforce the original conditions giving rise to them, thus maintaining a vicious circle of chemic and vital reactions.

In the treatment of these conditions electricity is usually associated with the other features of the "rest-cure," though also often found by the writer efficient without them; but experience has led me to vary this feature somewhat from the plans followed during my early association with the distinguished author of the rest-treatment of nervous disease. Instead of relying mainly on faradic stimulation of the muscles of the exterior of the body, the galvanic current is applied to the same parts by the mono-polar, labile method and large flexible electrodes, carrying from ten to forty milliampères. By this means even more thorough contractions may be obtained than with the faradic current, with a far greater stimulation of the vital processes of the periphery, resulting in a more useful reaction and quicker disappearance of cold extremities and other evidences of vasomotor stasis. Conjoined with this, a more profound impression is made on the spinal centers and the abdominal nerves and viscera by strong labile galvanic currents, which are rendered agreeable by means of large, saponified polar surfaces. The comparative results obtained with and without these features have proved that they are a most important part of the rest-cure methods, and may even be employed without the other features in cases that do not take kindly to the more rigorous measures of enforced rest and seclusion.

Hysteria. Electricity is an invaluable agent in hysteria, but the various currents that may be used require little comment, since any and all methods have met alike with success and failure. When the therapeutic results of the electric force cannot be separated from the possible chance of being mixed with the effects of suggestion, scientific investigation is at a serious disadvantage; yet it should not be forgotten that our efforts are directed toward a cure, in most instances, rather than investigation. A lack of rational explanation does not detract from the practical value that is so frequently demonstrated. When directly of value in hysteria, electricity doubtless acts by improving the organic functions.

Spinal irritation. Whatever may be the pathology of this ill-defined condition, there can be no question of the value of galvanic currents and franklinic sparks in the cases of nervous young people, chiefly young women, whose most striking objective symptom is a tenderness of the spinous processes of the vertebræ, and whose subjective symptoms are legion, centering about a weakened back. The treatment recommended for neurasthenia is also adapted to this condition, which is, in fact, not easily separated from neurasthenia; but the most useful feature is

unquestionably the direct electric treatment of the spine.

Insomnia. Though essentially a symptom rather than a disease, continued wakefulness may assume primary importance by the establishment of a vicious habit of the nervous system. The use of drugs for the correction of any but the most temporary of such conditions cannot be too greatly condemned, as there is danger of substituting an even more deplorable habit. Associated with a search for and correction of the causes of insomnia, the direct treatment should employ all the known external agencies for favorably altering nerve-habits, chief of which are electricity and massage. The former should rarely be applied immediately before sleep is sought, but earlier in the day, to permit of the reposeful reaction that in some cases does not appear for several hours. This is especially true of the earlier stages of treatment, when increased wakefulness will at times result temporarily if the application is too near the hour of retiring. The daily administration of general franklinic sparks, varied in power according to the case, is probably the most useful method, though it should be usually associated with either general faradic stimulation or the galvanic method recommended for neurasthenia. Under these means the insomnia will yield within a few weeks, and if the original cause can be removed, "Nature's sweet restorer" may be enjoyed in its pristine comfort.

Gastro-intestinal torpor and obstruction. The field of usefulness of electric currents in torpid conditions of the gastro-intestinal tract extends from the slight habitual constipation so common in gynecologic cases to the most profound intestinal paralysis and obstruction; and in the last-named conditions a large number of cases are now capable of being saved that would otherwise be beyond relief under medicinal or surgical treatment. The galvanic current is the most useful in all the conditions just named, doubtless owing to the fact that in simple constipation the stimulating action exerted by it (in common with the faradic current) on the muscular layers of the bowel, gall-bladder, and the various glandular ducts, is supplemented by a stimulation of the secretory functions of the stomach, liver, pancreas, and intestinal glands. This power of the galvanic current may be illustrated at any time by making an application to the parotid gland, and an external application of a strong labile current to the region of the liver will usually result in distinct evidences of increased discharge of bile. By the percutaneous method each organ may be brought under the mild influence of this current, but a greatly increased action is possible in the case of the stomach and the lower colon by placing one pole within the viscus. In moderate torpor the external method will usually suffice, and both currents may be used, either in succession or simultaneously.

Diseases of the bladder and urethra. In neuroses of the bladder and urethra, not demonstrably connected with organic disease, the faradic current, applied directly within the canal or cavity, is of much service. The fine-wire current is indicated. In incontinence of urine due to relaxation of the sphincters or to the presence of residual urine in a bladder affected with atony of the detrusor muscles the primary faradic current, applied by the swelling method, is of exceedingly great value. The method is also indicated as an adjuvant in the treatment of cystitis, with retention of residual urine. Chronic urethritis, disseminated or occurring in patches, demands the negative pole of a weak galvanic current as the most certain means of obtaining a radical cure. A purely physical use of electricity in diseases of the bladder is the electric-light cystoscope, by which the interior of the bladder may be illuminated and brought within the range of vision.

Neuroses of the vulva. The galvanic current has been recommended in pruritus vulvæ, ten milliampères positive being applied by means of a large pad-electrode. For irritative conditions of the vulva, giving rise to vaginismus, the same method is useful, accompanied by the fine-wire faradic current from an electrode in the introitus. It might be useful to moisten the cotton of the carbon electrode with a weak solution of cocaine, as the quick diffusion of this remedy by the current from the positive pole inward has been clearly proven.

Amenorrhea. In the suppressio mensium of young girls, due either to change of environment or habits or to catching cold, abdomino-dorsal galvanic applications will quickly restore the function. If anemia exists, the responses will naturally be slower, but the value of the applications mentioned, as a tonic to the blood-making organs, should indicate their persistent employment until the system can meet the periodic call upon it. Local treatment is, of course, not called for in such cases, though the value of the negative pole, applied within the cavity of the uterus, in reëstablishing and increasing the flow in parous women, is very well known.

Chlorosis. The employment of combined abdomino-dorsal currents, with large poles, in chlorosis is an extremely valuable adjuvant to iron and the eliminative treatment.

Sterility. One of the claims for electricity that has thus far been relatively neglected is its value in the treatment of matronal sterility due to disorders of the uterus and Fallopian tubes. The taste of American women is such as to call for but little work of this sort, but a fortunate experience of the writer among Hebrews, who universally desire off-

spring, has convinced him, by the unquestionable evidence of births from long-sterile women, that the method is one of great value. The mode of action may be by ovarian stimulation; but, as all the cases treated presented evidences of catarrhal affections of the uterus or of the uterus and tubes, some being veritable examples of patulous pus-tubes, a more reasonable explanation is that a cure of the catarrh has rendered it possible for an ovum to survive contact with secretions that had been poisonous. The methods are those used in the milder cases of chronic metritis.

Extra-uterine pregnancy. Notwithstanding the extreme position of some surgeons that an abdominal section should be performed as soon as reasonable suspicion of this unfortunate accident arises, the verdict of many is that electricity should be employed at once in case the condition is suspected to exist and the discovery is made prior to an intra-abdominal rupture of the sac. The advantages of this procedure are: No harm is done if the diagnosis is incorrect; if the pregnancy has not advanced to the fourth month the fetus and membranes will be absorbed, and no operation will be required; if the pregnancy has advanced beyond the fourth month the arrest of fetal vitality will render subsequent operation safer and lessen the chances of rupture. After the arrest of the vitality of the fetus the galvanic treatment should be continued for some months to promote absorption of the ovum itself, the incubative hyperplasia surrounding it, and any hematoma that may have formed.

Tumors of the breast. In acute mastitis after childbirth the faradic current will be found of considerable service in reducing congestion and inflammation, if applied at each renewal of the indispensable bandaging. Chronic inflammation of the breast, or of one or more of its lobes, is best treated by the galvanic current in association with massage, and speedy results may be anticipated.

For non-malignant tumors of the breast the galvanic current is almost a specific, whether the tumor be a mere nodular enlargement of the lobe or a fibroid. In either instance the external, percutaneous application of the current from well-proportioned electrodes will often be quite sufficient, though fibroid growths will at times require electro-puncture. It may be safely asserted that the prevalent employment of these means in such cases will effectually dispose of the doctrine advocated by some surgeons that any tumor of the breast should be removed on general principles.

Carcinoma. Under the stimulus of an increasing familiarity with the value of electricity in fibroid tumors, a method of treating malignant tumors by electrolysis that was first employed some years ago has been recently revived, and bids fair to be a weapon of vast importance in these affections. It consists essentially in the use of strong currents confined to the growth and the immediately subjacent tissue, whereby the malignant cell-structure is destroyed, either by electrolytic decomposition or by histologic shock. The latter method is the one claimed to occur by Inglis Parsons, who uses as strong a current as one of 600 milliampères, by multipuncture and sudden reversals of the current. Under the electrolytic method, which differs only in the absence of current reversals, the softer forms of carcinoma will be dissolved into a brownish liquid by currents of strengths of from 400 to 600 milliampères, and this, too, without pain, unless the action is carried beyond the diseased tissue. The method may, therefore, be employed in many cases without an anesthetic, and should be persisted in until all vestige of the growth has disappeared. This bipolar method should be followed by the monopolar method, also, in order that the affected channels of communication with the body may be traversed also by destructive currents. In epitheliomata of the softer kind it is probably true that these channels rather than the healthier tissues surrounding them receive the brunt of the current, for the physical reason that the carcinomatous tracts are better conductors than the less watery tissues. The degenerate tissue seems also to have a lessened vital resistance, as it is more easily rendered necrotic by the current. The electric methods have the additional advantage of controlling pain and hemorrhage during their employment. Besides the ease and the painless nature of the electric method of curing carcinomatous growths, it is probable that the power of following the growth through its roots and ramifications presents a most important advantage of this method over that by the knife or cautery.

The cosmetic applications of electricity. A review of the uses of electricity in the restoration of the health of women would be incomplete without a notice of the value of this agent in the removal of certain blemishes of the skin that at times do so much to disturb the mental health and equipoise. I allude to the removal of superfluous hair, moles, warts, nevi, and port-wine marks by the use of the electric needle. In the removal of hairs no other method can compare with electrolytic destruction of the hair papilla, and in the other troubles mentioned the advantage of electricity resides in its simplicity, relative painlessness, and the certainty of either leaving no scar or a smaller scar than treatment by any other method.

The Northwestern Society of Philadelphia meets on the second Tuesday of each month at the office of different members. The society is two years old and has a membership of thirty. Its objects are scientific and social.

SURGICAL DISEASES OF THE URINARY ORGANS.

BY W. S. FORBES, M.D.,
PROFESSOR OF ANATOMY, JEFFERSON MEDICAL COLLEGE; CLINICAL SURGEON TO THE JEFFERSON MEDICAL COLLEGE HOSPITAL.

IN this paper, and in the one or more succeeding, I shall confine myself to the diagnosis and treatment of that common and painful malady known as stone in the bladder, reserving for future occasions what I may have to say concerning some other affections of the urinary organs.

It is proper to observe here, by way of preface, that these organs, the kidney, the ureter, the bladder, the prostate gland, and the urethra, are liable to certain diseases to which surgeons have directed their special attention, and that these diseases have by common consent been called surgical diseases of the urinary organs. They have been conveniently classified in two divisions—those that are inflammatory and those that are obstructive in their nature. The inflammatory diseases are nephritis, ureteritis, cystitis, prostatitis, and urethritis. The obstructive diseases may be arranged under the following heads:

1. Stricture of the urethra.
2. Tumors of the bladder.
3. Tumors of the prostate gland.
4. Enlargement of the prostate gland.
5. Stone in the prostate gland.
6. Stone in the urethra.
7. Stone in the pelvis of the kidney.
8. Stone in the bladder.

It is of the last-named malady that I now wish to speak.

First, as to the diagnosis of stone in the bladder. To know accurately the disease one has to deal with and to point it out—this is diagnosis, and it is of the first importance. It is an art, and can only be successfully practised by obtaining an accurate knowledge of all the facts bearing on the case to be examined, and then deducing the true inference from these facts. To do this, skill and experience and accuracy of observation are necessary. The line of examination is held on the rational and on the physical symptoms.

The rational symptoms of stone in the bladder include frequency of urinating, the existence of pain, the altered character of the urine, together with the manner of its passage, and the passing of a little blood now and then. The result of a careful examination of the patient under these several headings may lead to a very pronounced *suspicion* as to the existence of stone, but its actual presence in the bladder can only be determined by passing into the bladder a sound, and with this instrument *there* touching the stone.

The description of the sound, together with the manner of passing it through the urethra and into the bladder, "the act of sounding," as it is called, I shall carefully describe when, further on, I shall speak of the physical symptoms of stone.

I repeat, that while the several rational symptoms or signs enumerated, viz., frequency of urinating, pain, the altered character of the urine, the manner of its passage from the bladder, and the presence of blood, point to stone, yet it must not be forgotten that the positive existence of stone can only be demonstrated by instrumental touch. In short, these rational signs are not always to be depended on; they exist in other affections of the urinary organs and are not peculiar to stone alone. Thus, the bladder when inflamed will not tolerate the presence of urine but to a limited amount, and in contracting to expel it pain will be developed, and if the inflammation be intense there may be some blood and pus mingled with the urine, thereby altering its character. Then there may be enlargement of the prostate gland compressing the urethra, or a stricture of the urethra in its membranous or its penile portion, altering the stream of urine in its passage. In how far then the rational signs may determine the surgeon to make an instrumental examination, it may be well to state:

First, in regard to the frequency of urinating; while this is found to be present for the most part in all the diseases of the urinary organs of an inflammatory nature, and especially when the inflammation is acute, yet it is a prominent symptom of stone, and in relation to the exact time of its occurrence is of much diagnostic value.

At night, when the patient is in bed and the body at rest, the bladder is found to tolerate a larger quantity of urine than it does during the day. Motion causes increased irritation of the bladder, and hence its more frequent contraction to expel its contents. The presence of a stone contributes under motion to increase this irritation and consequent frequency of the act of passing the urine. Hence, the value of the observation in regard to the time of increased activity on the part of the bladder. When there is enlargement of the prostate gland, without the existence of stone, there is greater frequency of urinating during the night than there is during the day.

In regard to the symptom of pain, its locality and the time of its occurrence are of much diagnostic significance. Riding over a rough road, a false step, a sudden or unexpected jar from any cause, will develop pain in the bladder, and especially at the extremity of the penis; and after making water, the bladder continuing to contract on a stone, there will, as a general thing, be greater pain than ordinarily, which will continue for some time, indeed until the urine, pouring down the ureters from

the kidneys, gently lifts the wall of the bladder from the hard stone; then the pain will in a measure cease. If the bladder is contracting, after urination, only on an enlarged or chronically inflamed prostate gland, the pain at this moment will not ordinarily be so great and is located for the most part in the perineum. When the bladder alone is inflamed, the pain comes on before making water and is located behind the pubic bone. In stricture of the urethra the pain is located for the most part at the seat of the stricture. In children having stone, there is not only severe pain after making water, but there is such a constant irritation between times, referred to the extremity of the penis, that pulling and rubbing the foreskin by the little sufferer is so frequent that this structure becomes hypertrophied to a marked degree. The amount of pain does not always depend on the size of the stone. A boy, eleven years old, from whom I removed by lithotomy a uric-acid stone ten grains in weight, had suffered excruciating pain for three years. When he came under my care, the mucous membrane of the rectum and the lower bowel projected eight inches from the anus, while straining, after making water. The mucous membrane and the submucous tissue were greatly thickened. The little patient was restored to health some weeks after the operation. Some months after this, a man, forty years old, consulted me on account of a bladder-trouble of long standing; but only of late had it pressed him to seek relief. His general health was and had been good. The rational symptoms were not well marked; only the appearance of blood to an increased amount of late after riding horse-back had awakened his anxiety. On sounding him I found a large stone and advised its removal. He consented, and I removed the calculus by bilateral lithotomy. It was found to be composed of triple phosphates, and measured 1¾ inches in its narrowest diameter, and 2½ inches in its longest diameter, and weighed 2 ounces and 180 grains. The man made a rapid and good recovery. The adult man may carry a small stone in his bladder for a long time without even suspecting the presence of a foreign body; the symptoms, the evidence of its presence, may at times be so slight as not to arrest his attention, or if noticed, are often attributed to other causes and are neglected, and thus the stone is allowed to increase in size until there is an awakening that drives him to seek relief.

In order to observe to what extent the urine is altered in character, it is necessary first to know its normal state; and, being a complex fluid, it is convenient in making an examination to have recourse to a form in which its healthy and its unhealthy constituents may be recorded side by side. The urine to be examined should be about four ounces or more in quantity. To obtain such a specimen the patient should always be instructed not to collect the first two or three tablespoonfuls in urinating, but to allow about this amount to pass off free, and then continuing to urinate let the fluid flow into a clean bottle, the object being to wash out the urethra, as it were, before collecting the specimen to be examined; otherwise it may contain urethral discharges, which, in examining the urine for information in regard to bladder-trouble, may be misleading. I have used the following form for a number of years in examining urine, and have found it satisfactory:

Analysis of Urine. Day. Month. Year.
Case. A. B.

PHYSICAL CHARACTERISTICS.

24 hours' quantity. Sediment.
Color.
Reaction.
Sp. gr.

NORMAL SUBSTANCES.

H_2So_4 test. Chlorides.
Indican. Phosphates.
Urates. Carbonates.
Uric acid. Sulphates.

PATHOLOGIC INGREDIENTS IN SOLUTION.

Sugar.
Albumin.
Others.

MICROSCOPIC EXAMINATION OF SEDIMENT.

Epithelial cells.
Pus-cells.
Crystals, etc.

Diagnosis.—

In a case of suspected stone the specific gravity of the urine, its reaction, its epithelial cells and its pus-cells, the sediment, and the crystals should be noted, and the record preserved for reference; for the urine should be examined repeatedly, and while the case is under observation the results of these examinations should be compared, for from the examination of the urine much light can be thrown on the subject as to the organ affected—whether prostate gland, bladder, or kidney. I shall speak of these subjects hereafter. The manner of the passage of the urine should be noticed, for at times the stone, if one be present, may roll along the neck of the bladder and suddenly occlude the internal meatus of the urethra, so that while making a comparatively full stream of urine it will at once cease to flow and great pain follow on the contraction of the bladder. In many cases of stone this symptom does not exist. It is because of this trouble—this sudden cessation of the stream when it has been flowing freely—that the patient finds that he can urinate

more comfortably by getting on his knees and lowering his abdomen, the stone then being away from the internal meatus of the urethra, until he has emptied his bladder.

The presence of blood, under certain conditions, is more significant of stone in the bladder than any of the other rational signs. The quantity may be, and generally is, small, and may appear only now and then; yet a little bleeding nearly always takes place at some period in the history of the case. In the nature of things we would expect it to appear. The delicate mucous membrane, lashed by the contractions of the muscular coat against so hard, and at times so rough, a body as a stone, is liable to be torn and to have its small capillary vessels ruptured, and bleeding is the consequence. The blood generally appears at the close of the act of making water. It may appear at other times, and again it may be found mixed with the body of the urine. In inflammation of the bladder and of the prostate gland, and in rare cases of tumor of the bladder-wall, some slight bleeding may occur, but this is not often the case.

Of the rational symptoms of stone, the frequency of urinating, the presence of blood, and pain, are of most value as diagnostic aids. Their existence is sufficiently suggestive to warrant the surgeon in asking permission of the patient to make an instrumental examination. This examination is made with a sound and with the index-finger. The sound is a solid steel instrument. For the adult it should be about twelve inches in length, two inches of which should be allowed for the handle. It should be smooth and highly polished throughout its entire extent. Its body should be of uniform size, and differ from the catheter in shape in that the sound should have a short and somewhat abrupt curve at its vesical extremity. For the small and delicate urethra of a child the size of the sound should be No. 7 of the common American scale, and for the adult No. 11 is large enough. The instrument should be but little smaller in diameter than the urethra, in order that it may be moved with freedom. The object of introducing the sound into the bladder should always be held in immediate view; it should be distinctly this—to convey to the mind of the surgeon through the sense of *touch* and through the sense of *hearing* whatever the instrument may come in contact with on its way to and while it is in the bladder—in short, he desires to know the condition of the urethra and the condition of the bladder and its contents.

Before making an instrumental examination of the urethra and bladder the surgeon should thoroughly sterilize his hands and his instruments. He should cleanse his finger-nails and wash and scrub his hands and forearms with soap and warm water, and soak them well in a warm solution of mercuric chloride in the proportion of one part of the chloride to one thousand parts of water. The instrument should be well cleaned and sterilized. The sterilizing of the instruments can be well accomplished by placing them in boiling water for ten minutes and then anointing them with vaselin, each twenty grains of which should contain one grain of carbolic acid. The patient should have his rectum well washed out and be under the influence of ether.

In order to introduce the sound the patient should be in the recumbent position, and the surgeon should stand on the left side of the patient. Holding the sound by its handle with the thumb and index-finger of his right hand and taking the penis by the corona glandis with the thumb and index-finger of his left hand, and holding the organ just in front of the lower part of the linea alba, the beak of the sound is placed in the external meatus of the urethra and carried gently under the pubic arch. The extremity of the sound will now come to the triangular ligament of the urethra, and if the surgeon will elevate the handle of the sound the beak will pass into the membranous part of the urethra and be grasped by the constrictor muscles that surround this portion of the urethra. If the surgeon will now wait for a moment or two, these muscles will relax their grasp, and the sound by its own weight will most probably glide into the prostatic portion of the urethra, and then, by gently depressing the handle of the sound, its vesical extremity will pass into the bladder. In the same manner the ordinary catheter should be passed into the bladder for the purpose of drawing off the urine. Unless there is a stricture or a foreign body in the urethra, there should be no difficulty whatever in the introduction of the catheter or the sound. It is surprising, in the absence of a stricture or a foreign body, to observe what difficulties are made to surround this simple operation of introducing the sound or catheter into the bladder. A knowledge of the anatomy of the parts, with gentleness and a little tact, will ordinarily secure the success of this simple operation.

On one occasion I saw too small a sound used; it passed by a piece of bone projecting into the urethra; a larger sound was used and passed only to the piece of bone, which was readily removed by a perineal incision.

When the curve of the vesical extremity of the sound is completely in the bladder, in the greater number of cases in which a stone is present, the sound will come at once in contact with it. If the stone is not at once felt, the sound should be turned gently on its long axis to the right and to the left and the extremity of its beak made to pass over the lowest point of the bladder, behind the prostate

gland. If, at this time, the surgeon, while holding the sound by the handle with the thumb and index-finger of his right hand, will anoint the index-finger of his left hand and introduce it into the rectum he can examine the prostate gland, its size, and its density, and note any irregularity of its contour that may exist, a matter that may be of much importance in any operative procedure that afterward may be necessary; he will be enabled also to observe the relative depth of the perineum and the relative position of the sound, as well as to dislodge a stone that may be hidden behind the prostate gland. He will also be enabled to observe any thickening or irregularity in the wall of the neighboring portion of the bladder. The surgeon in his first examination may fail to touch the stone with his sound; indeed, several examinations may be made with negative results; but when the stone is once touched with the sound the result is positively affirmative of its presence. The sensation imparted to the fingers holding the sound when it comes in contact with the stone is peculiar, and once experienced cannot fail to elicit attention, and if at this moment the sound is made to tap the stone a distinct and characteristic *click* will be *heard*. The sense of hearing is thus made to confirm the sense of touch. The surgeon should elicit this click. It is well to have a little urine in the bladder in making this examination. If there are more than two or three ounces of urine in the bladder a small stone will not be so readily detected. A large stone is easily found, but when a small stone is present it is of vast importance to the patient that it should be detected. If it is not detected, and if left alone, it will in all probability become a large stone. If a small stone is found, it may easily be removed by crushing. If there should be a very large stone, or a very hard one, such as a calcium oxalate formation, it may be a question as to whether it should be removed by crushing, by perineal lithotomy, or by suprapubic cystotomy. This question will engage our attention on a future occasion.

THERAPEUTICS, PRESENT AND PROSPECTIVE.[1]

BY C. W. BEAUMONT, M.D.,
OF CLARKSVILLE, TENN.

MATERIA medica, as now represented in our national dispensatories, exhibits a catalogue of substances, officinal and unofficinal, with their numerous preparations, simple and compound, dry, fluid, and solid, and some hundreds of miscellaneous formulæ, amounting to more than nineteen thousand parts. Deducting unofficinal drugs and formulæ and others used chiefly in the arts, there still remains a list exceeding sixteen thousand in number.

This perplexing accumulation of materials is inherited from a professional ancestry of centuries past, but, like many other legacies, it contains bequests that are undesirable and may well be relinquished. Marvellous as it must be regarded, on account of its magnitude, and also for certain titular emblems of therapeutic authority, attesting its real merit, there are nevertheless weighty objections to it, professional and popular, which demand serious consideration.

In the first category is the fact that a large number of drugs, long since passed into disuse because they are worthless, and many others of such feeble or doubtful power as to be practically useless, and others still not strictly medicinal, are retained.

All of these, together with unofficinal articles and formulæ, eliminated, the ponderous volume lying on our office tables might be reduced to a weight and dimensions that would facilitate instead of hindering ready and frequent reference to its contents. The classification and value of the individual drugs are almost wholly based upon clinical observations alone, and these furnished by many authors, the essential conditions of whose separate work are obviously so various as to render their reports often conflicting and sometimes positively contradictory.

The crudeness of the materials from which we must derive our medicinal resources, and the wide variability in quantity noticeable in each particular drug, resulting from physical, clinical, and meteorologic causes, necessarily leads to inappropriate dosage, and hence to uncertain effect. Even those subjected to careful assay, as, for example, fluid and solid extracts, and obtained from the very best pharmacists, are not wholly exempt from such changes, and when administered produce capricious effects, or, on the other hand, prove to be utterly inert—in either case bringing disappointment and mortification to the prescriber, and, it may be, peril to the patient. Accordingly, in ordering a formula, to be in dram doses, we do not know whether a full or a minimum dose will be had, or, indeed, whether much or little or any medicine at all is received.

But all professional objections weighed together do not counterbalance one that constitutes the only valid exception ever alleged, or that can be urged by the people against our therapeutic method, and that is the extremely offensive character of medicines, as we commonly prescribe and dispense them. This objection is the sole cause of the many alienations from us in the past, and of the daily addition of converts to the delusions of recusant and heretic self-styled physicians. We must admit this objection to be just and reasonable, inasmuch as each of us, from ample observation and perhaps a

[1] Read before the Tennessee Medical Society, April 12, 1892.

little personal experience, knows that our medicaments are generally obnoxious to taste, smell, and sight, often provoking the resentment of the most convivial stomach. The public denunciation is growing constantly in bitterness and vehemence, and the time has come when we cannot with justice to ourselves longer afford to debar a complaint, the further refusal to meet and adjudicate which will be most unwise with regard to our own interest, and ungenerous to our clientage.

Assuming that the foregoing objections to our therapeutics are indisputable, and that professional as well as popular interests demand their removal, a question that should overrule all others in this department of medicine confronts us, and can be answered alone by scientific medicine and in such manner as to silence at once and forever the perpetual clamor against our repulsive measures. The question the solution of which we are to work out, is not at all *can we*, but is rather *how may we* surely and speedily overcome and extinguish the single popular reproach incurred by us.

Fortunately, the present phase of therapeutics is one of transition from an empiric art, where mere clinical deductions had placed it, to that of an established science, to which it is steadily being elevated by the incessant labors of the physiologist, bio-chemist, microscopist, and of the bacteriologist. Enough has already been accomplished by them to assure us that rational medication is in sight, as, one by one, each drug in the catalogue shall have assigned to it a definite and well-ascertained physiologic force, as manifest in general effect, or by affinity for certain of the vital organs and tissues of the body. Future therapeutics is, therefore, to develop and complete a method already commenced, and will solve the several important problems suggested by our present method. Instead of crudities, perfect medicines are to be employed, and these must possess the essential qualities: purity, precise division, accurate dosage in the minutest bulk, uniform power, ready solubility, permanent form, and not be repulsive to sight, taste, or smell. With all our skill in formulating, together with that of the apothecary in preparing, especially of Galenic drugs, we cannot approach the standard indicated so long as we are compelled to draw our medicinal resources from the present officinal list; but that standard is nevertheless readily attainable, although we must give the credit of showing us the way to the extremes of nihilism, and the highest potencies in medicine.

It is more than probable that homeopathy and scientific medicine are approaching on converging lines a common ground, since on the one side there is to be seen a continuous, but stealthy advance from original nihilism, to really potent medication, while on the other there is an irrepressible progression toward the adoption of a therapeutic method that shall be at once effective and palatable.

With the absurd dogma of *similia similibus curantur*, coupled with the equally absurd assertion of the increased power of attenuations and dilutions of the thirtieth degree and upward, as formulated by Hahnemann, his system certainly suggested the practicability of exhibiting only the ultimate active principles of the botanic drugs, and reducing the inorganic bodies to a state of absolute purity.

We may well accept the method of alkaloidal and pure chemic medicines, as devised by the learned Dr. Burgraeve, as offering the best way of administering potent medicine in an agreeable form, and capable of producing certain and uniform effects. By this method alone may we overcome popular dislike to officinal medicaments, since all these may be administered in the form of tasteless granules.

Burgraeve's concentrated medicines have been in constant use for more than twenty years, and seem now to be growing in favor more rapidly than ever before. Several of our leading pharmacists, appreciating the great importance of such products, have already placed on the market a number of concentrations or alkaloids, which are steadily gaining the approval of physicians. They are offered in different forms, as tablets, granules, and solutions. Whenever pharmacists shall produce these substances in absolute purity, and all in the granule form, we will have attained a position reconciling, for all time to come, the public with therapeutic medicine.

Very few physicians are sufficiently familiar with chemic reactions to recognize the many changes occurring in crude medicines, imparting to their therapeutic effects such variableness as to render them uncertain, and, therefore, unreliable. For this reason, if no others were apparent, polypharmacy may well be abandoned in favor of a method possessing the inestimable advantages of alkaloid medication.

Of the many decided advantages of active-principle medication over other forms a few may be mentioned. Presented in the form of granules, the therapeutic effects of which are ascertained, the dosage is accurate, minute, and the effects constant, all of which are known to the prescriber, who may with confidence exhibit them even to little children, who will take them without dislike. In this form, medicines will be supplied—although they have not yet been brought fully up to the standard that we should require—equal to all demands and from pharmacies unsurpassed anywhere.

When it is considered that the number of medicines habitually prescribed by the general practi-

tioner is probably covered by the figure fifty, and certainly by one hundred, it is evident that the physician in remote parts of the country may carry a full armamentarium in a cabinet occupying little more space in the office than an amputating-case. The saddle-bags or buggy-case will readily contain a supply and assortment sufficient to meet the demands of his daily rounds, while the dispensing may be done without labor and loss of valuable time. The city physician, as well, may find his business greatly facilitated by carrying with him a case filled with these preparations, which he may dispense in less time than would be consumed in writing a prescription, with the necessary directions. He will also prevent substitution, adulteration, and repetition by others. It may be objected that we sometimes desire the effects of the whole plant, but there are few plants that, like those from which opium and quinine are derived, contain more than one active alkaloid, and the exceptions are few in which the one alkaloid does not truly represent the entire plant. These alkaloids, being capable of perfect chemic separation and exact assay, must afford an accurate measure of uniform physiologic power unobtainable by other means.

Here, then, on the ground where the two therapeutic extremes meet, scientific medicine is to stand, with all of the potent remedies that may be required at hand, and in a form acceptable to the most sensitive palate.

Besides the improvements made and others rapidly to follow in the preparation and exhibition of medicines, there are other and novel aspects from which future therapeutics may be contemplated. One is the practicability of forcing substantial medicines through the skin by means of the electric current—as, for instance, the introduction of iodine into a goitrous tumor. It is to be expected that an extended application of this method to other agents will follow.

Another, and it may be of the greatest possible value, is that which, accepting at its true worth the germ-origin of disease, seeks to repel or neutralize microörganisms by natural as well as by artificial antidotes. It has been clearly established that not the mere presence of a brood of microphytes within the body, which is a constant fact of animal life, but the toxic product generated by the parasites, is the actual exciting cause of disease. Moreover, recent bio-chemic researches have discovered the constant presence in the liquor sanguinis of a chemic agent or agents generated within the organism, and endowed with alexiteric and antidotal powers. These chemic substances are believed to be capable of actively resisting, neutralizing, and expelling poisonous matter introduced from without or fabricated within the body. For example, the specific poison pneumotoxin is always present in pneumonia until the crisis is reached, when, in favorable cases, the antidote named *anti-pneumotoxin* appearing, the poison diminishes rapidly in proportion to the development of its antagonist. This power of the living animal laboratory may yet define, if, indeed, it has not already done so, the *vis medicatrix naturæ* and justify a theory universally held half a century ago, and still avowed by not a few, that disease-processes are governed in their origin, progress, and termination, by invariable natural laws, and therefore all acute diseases being self-limited, medical art is wholly incompetent to subjugate them, or even to shorten their term of existence.

But the practice based upon that theory, that *vis medicatrix naturæ* should not be interfered with at all by active antidotal treatment, but that an expectant or negative plan only is admissible, cannot in the light of present knowledge be approved. Subject alone to natural laws, many cases of acute disease doubtless are and may be successfully resisted by the unaided organism, but who of us would consent to be an idle spectator of such a contest. Until we shall have acquired the necessary skill and method of correctly computing in any given case the relative antidotal energy of the organism to the virulence of the disease present, we cannot refuse to oppose or attack the noxious enemy. That a process by which the resisting power of the body to toxic influences may be estimated will be devised the recent brilliant triumphs of chemic physiology foreshadows, as only a matter of time not very distant for its verification. Not only has bio-chemistry already furnished the means for placing a limitation on the ravages of some of the more intensely contagious diseases, by successfully opposing or modifying and even preventing them, and also of a few that are not contagious, it is not anticipating too much to expect other results quite as marvellous to follow. In cases in which the organism is unprotected, or has failed to develop in due time the appropriate antitoxic material, thereby allowing disease to gain a lodgment within it, the deficiency will be supplied from artificial sources, always at our command. It is, therefore, quite apparent that in addition to the absolutely pure medicaments that are to be found only in the alkaloids and carefully assayed glucosides and metalloids, future therapeutics will also enjoin the general use of attenuated virus by inoculation. From these two sources are to be derived in future the most efficient measures with which to prevent, oppose, or modify all morbid operations. Steadily advancing and establishing the fixed invariable vital properties, general and specific, of individual drugs, this necessary work will not cease until the

entire catalogue of materia medica has been subjected to the crucial tests of bio-chemistry, and correctly classified and valued according to physiologic law.

Medical therapeutics represented by granules containing only the active principle of drugs, the definite vital force and direction of each being well ascertained, we may oppose disease with an intelligent simplicity or a very narrow combination of remedies. Such medicaments, together with appropriate attenuated virus, electricity more generally applied, and the development of the essential chemic agents to supply the organism with when defective or insufficient antidotal substances seem apparent, are to constitute the chief measures of the future. Prospective therapeutics therefore, starting with this, the brightest and best decade in medical history, is to place medicine immovably on the rock of public confidence. This done, the warfare with professional heresies is ended and the victory is ours, and its fruits must endnre while time shall last.

Summarized, the foregoing leads to these conclusions: Materia medica is burdened with a great mass of useless matter that may well be expunged; while that retained, from which we must derive our medicinal measures, is extremely offensive to those to whom we minister—the repulsive qualities of our medicines constitute the sole cause of disaffection and the estrangement of so many from us. It is incumbent upon us to overcome this objection, as so earnestly and justly demanded by our patrons; this can be achieved alone by the general employment of the pure alkaloids, glucosides, and metalloids. Future therapeutics is to rest upon the use of these substances, and to develop a systematized method of applying attenuated virus and electricity.

A thorough knowledge of the chemic elements of the animal organism now being acquired is to suggest and make practicable the use of these substances in neutralizing and modifying disease processes and supplying the body with such as it may be deficient in.

FISTULA IN ANO.[1]

By R. H. WORTHINGTON, M.D.,
OF DENVER, COLORADO;
MEMBER OF THE BRITISH MEDICAL ASSOCIATION; RECTAL SURGEON TO ST. LUKE'S HOSPITAL, DENVER.

FISTULA in ano is a very common affection, and one that in many cases may be prevented, if the patient will seek advice early and if the surgeon will act boldly and without delay. By far the larger number of cases commence with an abscess, either superficial or deeply situated in the ischio-rectal fossa. These deep abscesses are far the most serious, and, if not properly opened and drained, the pus is certain to burrow along the fascia and to burst into the rectum, as well as externally, making a deep fistula. With almost any abscess this may be prevented if the surgeon will avoid temporizing and poulticing as is very commonly done, and, instead, open the abscess freely, laying it open from end to end, preferably in a line radiating from the anus. The loculi in a large abscess should be thoroughly broken down, the wound irrigated, and the cavity lightly packed, not stuffed, with gauze, and thereby thoroughly drained. Hot aseptic poultices are useful until the acute inflammation has subsided.

If abscesses are treated in this way, fistula will very rarely occur; but, unfortunately, many patients do not seek advice in time, and too often the surgeon does not use the knife early enough, or freely enough, to obtain the best results. Deeply-seated fluctuation is often difficult to recognize, but it is far better to incise a hard, brawny, inflamed buttock before much pus has formed, than to delay a day after it has begun to break down, as these abscesses often extend and burrow very rapidly.

Fistula sometimes originates within the rectum from perforation of the mucous membrane by ulceration or traumatism. It is one of the several dangers of the injection of hemorrhoids with carbolic acid.

In examining a patient for fistula, he should lie on the side on which the fistula is, on a hard couch or table, exposed to a good light. The external opening is usually easily seen, but sometimes it is very small, and can only be detected by careful search, and by pressing with the fingers outward along the indurated track, so that a drop of pus may be made to exude from the orifice. The track can usually be closely followed by the induration along it, which feels like a wire under the skin, and often extends beyond the opening. A probe passed in at the opening will, if not too large, follow the track along the line of induration into the bowel in a simple case, and may then be felt there on the introduction of the finger, but if the track is tortuous this usually cannot be done, and the internal opening must be otherwise sought for.

If the fistula is found to extend to the mucous membrane, or even to the sphincter, an internal opening will almost always exist, though it may not be found, either at the time of examination or during operation; and if it does exist, and is not found, the operation will probably fail to cure.

Mr. Goodsall has pointed out that when the track of a fistula runs posteriorly to a line bisecting the anus laterally, it will usually be found to enter the rectum in the median line, directly posteriorly, and

[1] Read before the Denver and Arapahoe Medical Society, March 22, 1892.

very frequently between the two sphincters. If, however, it is all anterior to this line, it is more frequently a straight track, entering the bowel directly opposite the external opening.

The internal opening may be large and ragged, in which case there will usually be great pain, and it can easily be felt by the finger in the bowel. More often it is quite small, and feels like a minute dimple, or is elevated above the surface, pouting and soft, feeling very much like a gumboil. This pouting condition is often seen in the external openings of old fistulæ, and the pus exuding from them is thin and watery, with curdy flakes in it. Such a fistula may, if necessary, be left without operation for a time, as it is nearly quiescent, and the pus is not likely to burrow, and make new tracks, unless from some cause it should become inflamed, when the character of the pus will change, become more yellow, and more like the miscalled "laudable pus."

Any fistula is liable to extend and get worse from temporary obstruction of the external opening and the consequent retention of the discharge. Inflammation ensues and burrowing in any direction with formation of more sinuses may result.

The sooner a fistula is operated upon the better, unless it be in a state of acute inflammation. In this case the external opening should be dilated, the patient confined to a recumbent position and hot poultices applied until the inflammation has subsided.

There are a few cardinal rules to be observed in operating:

1. Only one division of the sphincters must be made, and that at right angles to the muscular fibers, and, if possible, the whole of both sphincters should not be divided, or incontinence is very likely to result. When there are two internal openings, it is better to lay open all communicating tracks *up to* the second opening in the bowel, but not to divide the sphincter more than once. If a cure is not obtained by one operation, a second one may be done later, with less danger of incontinence.

2. All tracks must be carefully laid open wherever they go and made to heal from the bottom, the tracks being followed in all their deviations. Exceptions to this rule must be made only in very long, deep fistulæ, opening externally at a great distance from the anus. In such a case an opening should be made in the track near the anus, the proximal portion, including the sphincter, laid open, and the distal portion curetted with a sharp spoon throughout its entire length, rendered aseptic by injections and stimulated to granulation.

3. All undermined and overhanging skin and fat should be freely removed, especially where the skin is thin and livid and lacking in vitality. Granulation goes on much more rapidly if this is done, and the subsequent contraction is less rather than greater.

4. Never make an opening into the bowel, as is advised by many older writers, unless you are absolutely certain that one does not exist. If there is none, it may be possible to cure the case without dividing the sphincter.

5. Tracks running up the rectum, under the mucous membrane, should be laid open as high as they extend. Authors differ on this point, but there is little or no danger in doing it, as hemorrhage can always be controlled if proper means are taken, and the fistula may not be cured if it is omitted.

After the incisions are made, and all the tracks are laid open, I usually scrape away the glistening lining membrane with the sharp spoon. If there is much induration, it is well to make an incision from one-eighth to one-fourth of an inch deep along the track. This is the well-known "back-cut" of the late Mr. Salmon, of London, and wonderfully promotes healing.

With strong, healthy patients there is little danger of cutting too much; in fact, the more you cut the better they seem to do, but with weak, delicate patients, especially with a tendency to pulmonary tuberculosis, or any chronic disease, one must cut as little as possible. This is especially necessary in women, where the sinuses run toward the perineum, as in them the dependence of the sphincter ani upon the sphincter vaginæ must always be remembered with a view of avoiding incontinence when the wounds heal.

In these cases it is, I think, frequently better to attempt immediate closure of the wound by deep sutures passing clear round the sinus, after it has been scraped out and disinfected. If this is to be attempted, the sphincters should be well dilated before incising, so as to insure temporary rest. A careful daily watch must be maintained, and, if pus appears, the sutures should at once be removed, the wound reopened and allowed to heal from the bottom by granulation in the usual way.

Healing by immediate closure may frequently be obtained when there is a single straight track, if the lining membrane and weak granulations in the sinus are thoroughly curetted away, and, if successful, much time will be saved; but if the operation be more extensive, and any lateral sinuses have to be laid open, it will usually fail. Time may be saved when there is a deep incision, leaving a large gap to be filled by granulation, by putting in a few deep sutures, but leaving them untied until granulation has begun, and then partially drawing the sides together, so as to narrow the gap, but not to close it.

After operating I pack the wound carefully with cotton to control the bleeding, and apply an ex-

ternal pad and T-bandage, and encourage suppuration and discharge by means of hot fomentations or poultices about the second or third day, if there is any inflammation. The bowels should be confined until about the fourth day, when a gentle but efficient purge will bring away everything, packing and all, as it will by then have become loosened by the discharges.

It is important, as the wound heals, to pass the finger or probe along its base daily, to break down any bridges that may form, so as to insure its healing from the bottom and to keep it clean. Much judgment is often required in the choice of local applications—sedative, stimulant, or caustic, or a simple bit of lint or gauze, to keep the lips apart. The surgeon must decide on the general treatment of each case on its requirements, and judge when to give stimulants, tonics or purgatives, a full diet or a light one, how long the patient should be confined to bed, etc.

We frequently hear of failure to cure fistula. This is sometimes due to a want of attention to the after-treatment. The wounds have a constant tendency to bridge over, leaving a fistula below, which does not heal and eventually breaks out again. A more common cause of failure is that the internal opening is not found and, therefore, not laid open, or that a small lateral sinus escapes the operator's notice, and he omits to cut it. During the healing of the wound pus must be carefully watched for, and, if more is found than should naturally arise from the granulating surfaces, its source must be ascertained. Some unsuspected sinus, either originally overlooked or in process of formation, is probably the seat of the mischief, and should be slit open at once. If everything is not laid open, failure must result.

Although an operation is indicated in most fistulæ, it is not always so. Some patients decline it, and demand that milder measures be tried. In others, the general state of health prohibits. I shall not now discuss the vexed question of curing fistula accompanying pulmonary tuberculosis, further than to say that, in my opinion, no operation should be undertaken while the lung-disease is at all active, and as long as there are any moist râles to be heard in the lungs. A cough is a decided contra-indication to operation; the succussion gives both pain and delays, sometimes prevents healing. When fistula complicates stricture of the rectum it is quite useless to touch the fistula without previously dilating or dividing the stricture. Kidney-disease puts any operation out of the question, and a man with an enlarged prostate is always a bad subject for rectal operations. Many patients, again, cannot, or will not, afford the time to lie up for the three or six weeks necessary for a cure of a deep fistula.

Fistula has been cured by the irritation caused by passing a probe into it, and sometimes irritating injections set up just the necessary degree of adhesive inflammation to cure, but such cases are extremely rare, and the treatment not at all to be depended upon. Moreover, fistulæ so cured are prone to break down and reopen. Still, such injections may be tried when an operation cannot be done, but should be preceded by forcible dilatation of the sphincters to give the part temporary rest, and, if possible, by curetting the internal surface of the sinus.

When purely palliative treatment is required, the patient must be kept as comfortable as possible, by careful regulation of the bowels, and by keeping the external opening free, to allow the discharge to escape easily. Dilatation by tents, or the insertion of a small drainage-tube, may be necessary to effect this. Allingham advises the use of a bone collar-stud, with a hole drilled through it, slipped into the orifice to keep it open. The parts must be kept clean and dry, and gauze or cotton used to absorb the discharge. A hot linseed-meal poultice, applied every night at bedtime, is very soothing; it allays inflammation and prevents retention of pus (which always gives pain) by promoting a free discharge.

LECTURES VERSUS RECITATIONS IN MEDICAL COLLEGES.

BY HENRY BIXBY HEMENWAY, A.M., M.D.,
OF EVANSTON, ILL.

ACCORDING to an ancient custom, adopted in every regular and well-governed college for medical instruction in this country, most of the didactic teaching is by lectures. Is it wise to adhere to the old system? The lecture was originally the means used for all education. With the progress in the art of printing, and with the advances made in the science of pedagogy in non-professional schools, the lecture has largely given place to the use of text-books. Even in some professional schools—theologic, for example—the lecture is of far less importance than the daily examination from a prescribed text-book. Is it not strange that the disciples of Æsculapius so long continue to use his methods of instruction?

In favor of the lecture-system it must be admitted that when the professor can speak at all fluently, he can make a good impression with less study. He can cover up his own lack of reading, and with a very superficial knowledge of his subject occupy his hour in a pleasing manner. Some time since I heard a didactic lecture upon a subject in materia medica. The speaker spoke easily and occupied his entire time, but he said practically nothing. He told the origin of the drug, and the fact that it had

been used in medicine from very early times. He did not tell the composition, method of preparation, dose, or exact physiologic action. He did give a few of the gross effects of the drug, and named some diseases in which it is used, but failed to give the exact indications for its administration. It would be unjust to regard such teaching as representative of the work of our schools, but similar lectures are given more or less frequently in most of them.

When we say that the lecture was the original form of instruction, we do not necessarily mean that questions were excluded, as they are in modern lectures. On the contrary, that prince of teachers, Socrates, made his lectures far more interesting and effective by frequent interrogations.

It has been claimed for the pure lecture-system that it gives a better opportunity for the teacher to impress his individuality upon the student, but I feel that this is not the truth. The lecturer gives his ideas, and the student absorbs what he can, but is not prepared to recognize what ideas are original. Everyone who has a broad acquaintance with the professional schools must recognize the fact that the best students come, as a rule, from those institutions in which the quiz is a special feature; and, probably, he will further note that he remembers most vividly the instructions received from his quiz-master.

The lecture-system tends to narrow the student's mind. The student rarely knows of what the next lecture is to treat, and so cannot, if he would, look up the ideas of others. After the lecture he is inclined to learn all that he can of the professor's lecture, rather than to spend his time in reading his text-books. In fact, some professors give their students to distinctly understand that they must take their professor's ideas, and not those of other authorities. It is only a small man who would thus give his *ipse dixit*.

It frequently happens that a lecturer is misunderstood, when both the speaker and the hearer suppose that there is a perfect understanding. The error is seldom discovered except by the quiz.

The present method does not at all prepare the student for his life-work. He may practically go to sleep while listening to a dull lecture, or he may be spell-bound by the eloquent speaker. At best, there is a decided feeling of exhaustion after listening to lectures for a few weeks. Original thought or reasoning is reduced to a minimum.

Against the quiz method of instruction it is often urged that it takes too long to get around a large class to devote much time to that method. True it does take time, but, so far as I know, in our professional schools the quiz is not generally utilized in the most profitable manner. A few hurried questions are occasionally asked in regard to the subject of past lectures only.

I would suggest that in our didactic teaching the text-book be more generally used. I remember having provided myself, during my first year at college, with several text-books recommended in the catalogue. In pathology, for example, it was so absolutely impossible to follow the professor with the text-book that the student has never yet been able to wade through the pages of his German author. Having been unable to comprehend the work when studying the subject, he is now afflicted with mental dyspepsia and nausea whenever he reads a few pages of that particular book. The teacher should be a leader, or he is a crammer instead of an educator. He should instruct the student how to read. A poor book as a text, thoroughly mastered, is far better than a good book glanced at. When one text-book on a subject is understood by the student, others can be more easily comprehended.

What is the object of the ordinary lecture on anatomy? It is practically only a recital of a few pages from Gray, and generally less accurate. In histology, chemistry, anatomy, and to some degree in pathology and materia medica, the most profitable work can be done in the laboratory. The student will learn more in less time, and with less fatigue. In other cases, even including as far as possible clinical teaching, an assigned lesson should be given out beforehand. As far as possible, the teacher should make his remarks explanatory and supplementary to the answers of the students. In that way the student is practically obliged to study, and he soon learns to read different authors with discrimination.

If it is a fact that the student remembers most vividly the instructions in the quiz-class; if in the quiz-class the student can most clearly comprehend the ideas of the teacher, is it not a foolish custom to assign the quiz-classes to assistants, sometimes undergraduates. There was a time when the primary school was assigned to the poorest teacher. To-day the best school-boards regard the primary teacher's place as the most difficult to fill. It is to be hoped that a like change will soon be noticed in the general opinion relative to the quiz-master.

He who is fit to enter a medical school should be treated as a man, and not as a sponge. We might learn a lesson at the soda-fountain. In charging the water with carbonic acid gas, high pressure (eminent professors) is not sufficient. A little agitation (quizzing) will cause the water (the student) to absorb many times as much of the gas (instruction).

We would not entirely abolish the lecture-system, but rather revive the method of Socrates, and adapt it to the present time. By the use of text-books

the student may be prepared for the questioner, and the lecture should be limited to discussing with the class disputed points, or emphasizing important subjects.

ANALYTIC NOTES ON COMMERCIAL COD-LIVER OIL EMULSIONS.

BY HENRY LEFFMANN, M.D.,
AND
WILLIAM BEAM, M.D.,
OF PHILADELPHIA.

THE excellence of an emulsion of cod-liver oil depends, of course, upon the proportion of oil present and upon the perfection of the emulsification. The latter condition may be roughly estimated by the facility with which the oil separates on standing, but the proportion present can only be determined by analytic methods. Since these preparations are extensively employed by physicians, it seemed to be of interest to determine the strength of commercial varieties, some of which make definite claims as to quality. The analytic investigations here noted were carried out by the most approved methods for fat-extraction, as applied in milk-analysis. The samples were obtained from a wholesale house and in the original packages. Care was taken to mix each sample thoroughly before making the analysis.

Brand.	Per cent. of oil claimed.	Per cent. of oil found (by volume).	Remarks.
"Williams's emulsion of cod-liver oil with hypophosphite of lime."	50	49.9	
"Phillips's palatable emulsion of cod-liver oil."	50	49.5	Pancreatized.
"Scott's emulsion of pure cod-liver oil."	50	49.5	
"Hydroleine."	66.6	44.2	Pancreatized; contains salicylic alcohol.
"Maltine with cod-liver oil."	30	35.9	Much maltose.
"Baker's emulson of cod-liver oil with hypophosphites.	50	10.7	
" (second sample.)	50	18.0	
"Baker's pure cod-liver oil with extract of malt."	....	8.4	Much maltose.
"Wilber's pure cod-liver oil and phosphates."	....	37 3	
"Wampole's perfected and tasteless preparation of cod-liver oil."	"the curative agents from 25 per cent. pure Norwegian cod-liver oil."	None.	14 per cent. alcohol.

The sample (Wampole's) last-named is accompanied by a circular stating that "the oil in this preparation is in positive solution," and also a certificate from a professional chemist to the following effect: "I have examined the sample which you sent me, marked Wampole's perfected and tasteless solution containing the essential curative agents of cod-liver oil, and I find that it contains combined phosphorus in several forms, and the peculiar principles of wild cherry bark, and it also carries an amount of combined iodine, such as is found in a volume of cod-liver oil equal to 25 per cent. of the solution; that is, one tablespoonful of the mixture carries the amount of combined iodine found in a teaspoonful of cod-liver oil." The sample analyzed by us contains 14 per cent. of alcohol and no appreciable amount of iodine.

It is not inopportune to discuss briefly some of the chemical questions relating to the therapeutic value of cod-liver oil. It is probable that the modern knowledge of causation and nature of phthisis, recognizing it as definitely due to a specific germ, will modify materially the therapeutic importance of such a substance as cod-liver oil, but incidental to the supposed especial nourishing function of the fatty matter, it has often been suggested that some accessory ingredients may be of value.

For instance, iodine has often received credit, but it has been known for a long time that the proportion of this element is extremely minute, ranging from 0.001 to 0.004 per cent. It is evidently impossible to attribute the medicinal value of the oil to the traces of iodine present, unless we are willing to accept the absurd doctrine of infinitesimals. The proportion of iodine in dried cod-fish and in herring, is considerably greater than in the oil.

Theoretic considerations would lead to the view that the best emulsions are those made with pancreatin, in association with the least possible quantity of gum, glycerol, or sugar. The presence of any considerable amount of the more easily fermentable sugars, such as maltose or glucose must be regarded as objectionable. The presence of salicylic acid and of notable proportions of alcohol will be still more serious, for, as we have elsewhere shown, the former interferes decidedly with the action of the pancreatic ferment, and the latter should certainly not be employed except under specific and regulated conditions of dosage. Thus "hydroleine," an otherwise satisfactory emulsion (although not found to contain the amount of oil indicated in the published formula), is objectionable from the presence of salicylic acid, and in the Wampole preparation we have, in addition to the fact that it contains no appreciable amount of oil, the presence of 14 per cent. of alcohol as a most serious drawback to its use.

Dr. Benjamin Lee has been elected professor of Orthopedics at the Philadelphia Polyclinic.

WILL THE GENERAL PRACTITIONER CEASE TO EXIST, AND HIS PLACE BE TAKEN BY SPECIALISTS?

By JOHN GRAHAM, M.D.,
of Philadelphia.

In language written and spoken, we are forcibly informed that this is an age of progress; that old things must give way to new; and that the relentless scythe of Time will hew down everything unsuited to this advanced and advancing age.

Among the many early doomed to extinction, according to some writers and teachers, is a class endeared to all through the memory of bygone days—the general practitioner, the family physician. We are told that he must go, and his place be filled by the specialist.

Some kindly describe him to us. He is always short, very stout, a little past middle life, and wears spectacles. His resources to battle with disease, generally speaking, consist of bleeding, blisters, quinine, and calomel, with an occasional dose of salts. The humorous journals assist in diffusing a knowledge of him.

If this description is a correct one as he at present exists, then, indeed, he must go, for he is no longer suited to his environment; but, as a matter of fact, the good-natured old doctor here described has long since almost disappeared. Like the partridge of Pennsylvania, he exists only in small numbers, in the mountain districts; but his improved type—the practitioner of to-day—holds his place by merit, in this and in every other civilized land, and is here to stay.

Year by year the study of medicine covers a wider field, until now no mind is broad enough, or working life long enough, to enable one to become an expert in all its branches. But, as an army needs a general to guide and direct it; to be thoroughly conversant with the art of war, in all its details; capable of knowing and selecting a good engineer, artillery officer, commissary-general, or corps-commander, and assigning the right man to the right place; so in our battle with the enemy—disease—we need a commander to guide and direct: a man with a broad knowledge of general medicine, and thoroughly posted, by bedside experience, in all its branches. There are plenty of such men, and the wise patient will seek the advice of such first, and, if a specialist is needed, will depend upon the family physician to make the selection.

If my judgment—gained by a somewhat large experience—is correct, the majority of cases, as they come to us, can be best treated by the general practitioner; the minority alone can with advantage be assigned to the specialist.

Most diseases have complications. The patient depressed by a uterine catarrh may, as a result of indiscreet exposure, develop a solidified lung.. A pelvic inflammation, as in a case I recently saw, may be but a complication of typhoid fever. Here, a single visit from the specialist is all that is probably necessary. The case will be best managed by the general practitioner.

The advertising quack will not agree with me. His advice is: "Shun the family doctor; come to a specialist—me." How many poor invalids would have saved time, money, and health by having come to the physician first, to have been guided by his counsel. The general public, even when educated, is alone utterly unable to make a proper selection; and, as a matter of fact, the office of the quack is filled with lawyers, clergymen, and men who know everything except medicine.

Our first-class medical colleges graduate yearly hundreds of young men and send them forth thoroughly prepared in all departments of medicine and lacking only experience to enable them to become first-class general practitioners; but, alas, the educated man too often shrinks from physical toil, and the young physician is not attracted to general practice, with its long hours of labor and sacrifice of social pleasures.

The brilliant results recently accomplished in some departments of medicine, notably in gynecology, with the large fees and shorter hours of work naturally attract the young graduate. So great is this tendency that what would ordinarily be for the good and the development of the profession has degenerated into an evil; the specialties more than general practice are becoming overstocked.

No man should embark in a specialty until he has practised medicine for five or six years. He should learn by experience not what branch he likes, but that which he is best adapted to.

I recently heard a teacher say to a mother: "Your son is bright, studies easily, and is industrious, but cannot use his hands." Such a boy might in after-years be successful in the treatment of nervous diseases, but what a failure he would make as a surgeon.

In regard to the gynecologists, I have always thought that their ranks should be filled, not by general practitioners, but by young surgeons—young men thoroughly grounded in the theory and practice of general surgery.

A man of moderate ability, industrious, and conscientious, may lead a useful life as a general practitioner, and will be fairly remunerated for his services; but a specialist with only moderate ability in his branch will be a gloomy failure.

Wilhelm Czermak has been made professor extraordinary of Ophthalmology at the University of Innsbruck.

MEDICAL PROGRESS.

Extra-genital Syphilitic Infection.—The primary lesion of syphilis may be genital; peri-genital, in the genito-crural folds, on the symphysis, in the inguinal regions, on the perineum, on the inner surface of the thighs, in the anal region; or extra-genital, on the skin or mucous membranes remote from the genital region.

During ten years, NEUMANN (*Bericht des k.-k. allgemeinen Krankenhauses für das Jahr* 1890) has observed eighty-eight cases of extra-genital chancre—thirty-seven in males and fifty-one in females. In eighteen cases—six in males and twelve in females—the upper lip was the seat of the lesion. The infection was usually transmitted by kissing. In one case the transmission was by drinking from a glass previously used by a syphilitic; in another case, by a bite; in one case, by the sucking of the lip of the grandmother by a child of a syphilitic father, the mother, who had nursed the child, escaping In twenty-eight cases—nine in males and nineteen in females—the lower lip was the seat of primary lesion. Among the modes of conveyance were kissing and the use in common of eating utensils. In eight cases—six in males and two in females—chancres appeared at the angle of the mouth. In one case, the infection was ascribed to smoking a thrown-away cigar. In two cases, chancres appeared upon the cheek—in one case in a man, in the other in a woman. In the latter the infection was conveyed by kissing. In five cases—four in males and one in a female—the primary lesion appeared upon the chin. The four men were infected through shaving. A male presented a chancre of the posterior wall of the pharynx and of the left palatine arch. The mode of infection was not determinable. Two women presented chancres of the tonsils. One was infected by a spoon. Chancres appeared on the alæ nasi in three cases—two in males and one in a female. In the last, the infection was conveyed by scratching the excoriated nose with the finger-nail, after cleansing a vessel in which a syphilitic had bathed. Two men presented chancres of the eyelids. The fingers and hands were the seat of infection in eleven cases—six in men and five in women. Among the modes of transmission were washing infected linen and a bite. Four chancres were found upon the nipples in women. In two instances, the infection was conveyed by syphilitic infants; in one, by a bite; in one, by the kiss of a syphilitic man. A child presented a chancre of the umbilicus. The mother had been infected in the eighth month of pregnancy. The child had no evidences of infection at birth, but when five months old was infected by the secretion from the papules of the mother. Three women presented chancres of the anus.—*Internationale klinische Rundschau*, 1892, No. 15, p. 603.

Acute Bulbar Palsy of Inflammatory Origin.—VANDERVELDE (*Journal de Médecine, de Chirurgie, et de Pharmacologie*, 1892, No. 14, p. 225) has recorded the case of a man, twenty-four years old, with a history of alcoholism but not of syphilis, who three weeks previously to coming under observation had complained of sore-throat. Twelve days later the difficulty was worse and fever was present. It became necessary to introduce nourishment by means of an esophageal tube. In three days more, tingling had appeared in the lower extremities, with increasing difficulty of progression. Mild attacks of headache, of brief duration, occurred. For several days there had been no sleep. Attempts to arise from bed induced vertigo. There was ringing in the ears. Vision had been impaired for two weeks. The pupils were dilated and unequal; the right was larger than the left; both were sensitive to light. There was bilateral convergent strabismus; the deviation was at first the greater on the right; subsequently it became the more decided on the left. The difficulty of deglutition increased. The uvula was deviated to the right; the velum palati to the left. The mobility of the tongue was unimpaired. The lines of the lower part of the face were obliterated. The nose was drawn to the right. The movements of the extremities were preserved. In walking, the feet were separated; the right leg was dragged; there was a tendency to fall to the right. The mental condition prevented a study of the knee-jerks; later, the right knee-jerk was elicited; there was no ankle-clonus; the cremasteric reflex was preserved; the superficial reflexes were preserved, but enfeebled. The muscular power of the hands, as measured by the dynamometer, was diminished, but alike on both sides. The electric reactions were preserved. The pulse was 140; the respiration 40; the temperature 101.8°. The bowels were constipated. The urine contained neither albumin nor sugar. The condition of the patient steadily grew worse. Dyspnea, cyanosis, convulsions, and coma were followed by death. At the autopsy, inflammation of the ganglion-cells in the anterior horns of the medulla oblongata was found at the level of the decussation of the pyramids. There was slight contiguous involvement of the gray matter of the posterior horns and also evidences of beginning descending degeneration.

The Bacillus of Measles.—CANON and PIELICKE (*Berliner klin. Wochenschr.*, 1892, No. 16, p. 378) examined the blood in fourteen cases of measles, in cover-glass preparations stained with methylene-blue and eosin, and found constantly one kind of bacillus. The organisms were at times uniformly stained; at other times they were more deeply stained at the extremities. They were of variable size; some appeared like diplococci; others were as long as the radius, and still others as long as the diameter of a red blood-corpuscle. In the cover-glass preparations, the bacilli were arranged singly and in groups, with a tendency to lie parallel with one another. The organisms were found throughout the whole course of the disease—in one case, in fact, for three days after defervescence had taken place. They appeared in largest number at the period of crisis. In seven children just recovering from measles, and in one fatal case of uncomplicated measles examined ten hours after death, bacilli could not be found in the blood. The bacilli did not retain the stain of Gram's method. Bacilli resembling those found in the blood were present in the sputum and in the nasal and conjunctival secretion of children with measles. Inoculations of the blood upon glycerin-agar, blood-serum, or human milk, remained sterile. In three cases, inoculations upon bouillon were followed by the development of a bacillus resembling that found in the blood.

The Blood during Treatment with Tuberculin.—In a study of the blood of tuberculous patients being treated with tuberculin, BOTKIN (*Deutsche med. Wochenschr.*, No. 15, 1892, p. 321) found that after the injections an acute leukocytosis became evident, all varieties of the white cells being increased. On the day after the reaction, the number of leukocytes rapidly diminished, the majority probably undergoing destruction, as indicated by an increased number of blood-plaques. This manifestation was usually simultaneous with the maximum decline of temperature usually observed to follow the reaction. The condition is comparable with the blood-crisis of some of the acute infectious diseases that are attended with fever. The changes in the blood may take place in cases in which the temperature does not rise. The increase in the number of eosinophile cells may occur in conjunction not only with chronic cutaneous affections but also with acute transitory exanthems that complicate some therapeutic procedures.

THERAPEUTIC NOTES.

The Treatment of Metrorrhagia.—EDIS (*British Medical Journal*, No. 1630, p. 648) considers the various conditions that give rise to metrorrhagia, and indicates the best means of treatment. When uterine hemorrhage results from constitutional or general conditions, its repression is not always wise. In certain cases of heart-disease moderate uterine hemorrhage seems to relieve the cardiac symptoms. In such cases potassium bromide, with strophanthus, digitalis, or aconite, is indicated. Iron is also useful. If the function of the liver be deranged, attention to diet, abstention from alcohol, encouraging the action of the skin and the administration of a few grains of calomel, followed in the early morning by a brisk saline aperient, will be attended with good results. If disease of the kidneys exists, vicarious action of the skin and bowels, by means of diaphoretics and purgatives, should be encouraged. The reliable remedies available for controlling uterine hemorrhage are few in number. Ergot is one of the most potent; its efficacy is increased by combination with strychnine and cinchona. Hydrastis canadensis is a valuable agent in many cases of uterine fibroid. Hamamelis is useful in some cases. Ordinary astringents, such as gallic and sulphuric acids, have little influence in restraining hemorrhage. Quinine and strychnine, alone or in combination, will often succeed in controlling hemorrhage when the system is depressed, as a result of repeated or protracted loss of blood. Potassium bromide is one of the best remedies in cases of hemorrhagic chlorosis, ovarian irritation, or hematocele. Potassium chlorate and borax, in combination with ergot and cannabis indica, have been recommended. When the hemorrhage has been severe or protracted, opium has a wonderful restorative effect. Combination with quinine or cinchona seems to enhance the value of the remedy. Iron should not be resorted to when the presence of a foreign body in the cavity of the uterus is suspected. On the other hand, when from antecedent anemia, the blood has become so attenuated as to pass readily through the capillaries, and in some cases of intra-mural fibroids, iron does much good. Locally, the hot vaginal douche, at a temperature of from 110° to 115° F., is often of service. In all severe cases absolute rest in the horizontal position, preferably in bed, is indicated. The application of carbolic acid by means of a suitable probe to the cervical canal and even to the cavity of the uterus may, in appropriate cases, control the hemorrhage for a time. Free scarification of the cervix, by relieving congestion, sometimes succeeds in arresting uterine hemorrhage. When, without recognizable cause, uterine hemorrhage persists and ordinary remedies have failed, the cervix should be dilated and the cavity of the uterus explored.

The Mechanism and Treatment of Asthma.—KINNEAR (*New York Medical Journal*, lv, 17, p. 458) expresses the view that the asthmatic paroxysm is dependent upon hyperemia of the pneumogastric center in the medulla induced by various influences. A rational mode of treatment would be directed to the control of the blood-supply of the nervous system. With this end in view, it is recommended that an ice-bag be applied to the spine for longer or shorter periods. Such practice has been attended with good results, immediate and remote, the paroxysm being terminated and concomitant symptoms being relieved.

Gold and Sodium Chloride in the Treatment of Paretic Dementia.—BOUBILA (*Annales Médico-psychol.*, Janv. et Mars, 1892) reports the results obtained in the treatment of paretic dementia by means of gold and sodium chloride, in doses varying from a sixtieth to a twelfth of a grain, morning and night. Curative effects were not obtained. In the first stage, the remissions were favorably influenced; in the second stage, the general condition was improved, the weight and the number of red blood-corpuscles increasing.—*Rev. Gén. de Clin. et de Thér.*, 1892, No. 14, p. 214.

Glycerin in the Treatment of Burns.—GRIGORECU (*Répert. de Pharm.*, February, 1892) recommends the treatment of burns by means of pure glycerin. Several drops are applied to the burned part and gentle friction is employed. At first a sense of smarting is perceived to which a sort of anesthesia succeeds. The inflammation seems thus to be averted; in addition, the desquamation of the epithelium takes place little by little, and the resulting cicatrix is less marked than otherwise. The burned part is to be constantly kept moistened by the glycerin.—*Journ. de Méd.*, 1892, No. 11, p. 134.

Insufflation for Tuberculosis of the Larynx.—

℞.—Menthol.	gr. xx-xl.
Pulv. iodoformi	ʒiv.
Pulv. acid. boric.	ʒiv.
Pulv. calcii phosphat. . . .	ʒj.—M.

S.—A sufficient quantity by insufflation, morning and evening.—*L'Union Médicale*, No. 42.

Treatment of Erysipelas.—SCHNEIDER (*Centralbl. für Chirurgie*, 1892, No. 15, p. 305) strongly endorses the treatment of erysipelas by the application of a thick coating of collodion in a broad band beyond and surrounding the area of inflammation.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

PHILADELPHIA.

SATURDAY, MAY 21, 1892.

A COUPLE OF KEELEY IMITATORS.

ACCORDING to Keeleyism, there are now in the United States about 60 recognized or genuine (save the word !) "institutes" and 214 imitation systems at work. The mere statement, together with the very significant fact that even the penny-newspaporial stomach is beginning to turn against the nauseous dose, indicates that the end of the beastly carnival is fast approaching. The "institute" literature is commencing to abuse the newspaper, because sporadically the newspaper, as we have said, begins to feel qualms and weakness at the pit of its stomach —metaphorically speaking. Herein lies hope.

To keep track of this hurly-burly of drunken stupidity and devilish roguery would take a Mephistophelean wit and endless time and patience. Our table is loaded with evidences *ad nauseam*. From the mass and mess we cite a couple of examples, thanking the kind correspondent who has sent us the original letters from which we quote. For the sake of brevity we leave out the flaming letter-heads, with the array of directors, officers, institutes, and branches, etc., and give only the significant portions. Comment is, of course, unnecessary. Filth can scarcely be fouler; the human mind can hardly fall lower. "Thin-skinned ethical sentiment" need only "fire at" them their own boomerangs:

MY DEAR DOCTOR: Your letter of the — is before me. In answer allow me to say a full, free confession is a good thing for the soul. We honor your frankness, and feel better acquainted since receiving your letter.

In reply, permit me to say my thought regarding your relation to us is that you had better wait for a little time, say two or three months, and then I feel very sure that we shall have a branch institute where we shall be glad to place you in charge, with reasonable assurance of a good business before you.

Some capital is necessary to establish a branch, which you do not seem to be ready for, but, when once established, we do not doubt you may be the proper person to take it in charge if your tender conscience can surmount the ethical difficulties.

Regarding these bugbears which seem to frighten your professional timidity, permit me to say I do not cure alcoholism or any other disease with a formula. The treatment is administered according to indications after I carefully individualize my cases.

My treatment has been given to the profession in a general way. My particular methods of compounding drugs are protected by a trade name which, you will observe, is quite colloquial (bichloride of gold[1]) and quite as unscientific as my method seems to be to you.

Of this unprofessional feature I beg leave to say I most heartily agree with you and my brethren in the sentiment that no conscientious physician who is worthy of his title in that high office will withhold any good thing from those to whom it is due.

Of this particular treatment, however, I must say it is very peculiar to itself. The disease is unlike any other, the successful treatment of it depending quite as much upon methods as matter. We do not believe it could be successfully handled in a general practice.

We also feel certain if all we think we know were thrown wide open to the public, great harm would come of it. The above remark may seem to say, by implication, we are wiser than others, but not so, good brother.

Any man who has brains enough to have honestly won the title of M.D., and has been reasonably favored by the great Father of us all with a peculiar adaptability to this strangely peculiar work, may do all that we have done if he will "sweat the great drops of blood falling down to the ground," that have made us gray in the last seven years; he too may be conscious of bearing some humble part in rescuing the perishing, though he may be criticised by those who have neither the patience or skill, good sense or conviction to do a like grand work.

[1] In another letter the writer says: "Regarding 'bichloride of gold,' criticised by the Editor of THE MEDICAL NEWS, November 14, 1891, permit me to say he is correct in saying that, chemically speaking, there is no such thing as bichloride of gold in stable solution. The term is one used in the market to indicate the chloride of gold and sodium. It is in this sense that we use the term."

When we are thus fully understood by members of the profession, we are quite ready to suffer any criticism which their thin-skinned ethical sentiment may fire at us.

Yours to rescue the perishing rather than please sentimental notions,

—— —— ——, M.D., *Pres.*

Fearing this, from the professional standpoint, may be inconclusive, the business agent of the company thus writes on the following day:

DEAR SIR: Let us, from the business office of the company, add a word supplementing what our Dr. ——— has already said to you.

If the doctor has not convinced you of his not unprofessional attitude, it cannot be contrary to medical ethics if you should offer some of our shares to the people of your community, and so give us the opportunity to pay you a full agent's commission of 10 per cent. on the par value of the shares you sell. Please take this under consideration.

We know the doctor is correct in his position, yet some of the more strict sect may not coincide with us.

The doctor feels that you can be of service to the company, and to himself individually, and we hope that you will be able to see your way clear to join us in our view of the doctor's position and take hold with us.

In any event please let us hear from you regarding the sale of our shares.

Yours truly,

—— —— —— ——

Printed blanks for subscription are enclosed; notices to stockholders of great dividends sure to follow, and "dodgers" promising fortunes, assuring in tremendous capitals that this is "a splendid investment for women," etc. etc. Then follows a typewritten extract from "a confidential letter sent to shareholders (sent herewith for your information)":

We are warranted in giving the most positive assurance that our shares must pay, as an investment, far better than the stock of the most successful business corporations.

We say confidentially to those who are likely to be interested with us as shareholders, that our profit on every case treated for alcoholism is over $50. This alone, you will see, should enable us to pay dividends of from 25 per cent. to 40 per cent., and this is not our only source of revenue. We are establishing branch institutes, and soon will have them in every State. These branches are under our control, and will pay us a certain price for every case treated, so that in the course of a few months our income from this source alone will be very large. This income from the two sources, you will understand, comes to our stockholders in the form of dividends.

We need say nothing here of the moral and benevolent aspect of our work, more than that we are doing a great service to humanity in reclaiming the drunkard, and that fact is recognized and made a valuable aid in the furtherance of the sale of our stock.

It may interest you to know something of Dr. Keeley's experience at Dwight, Ill. His balance-sheet for last year showed a net profit of $1,400,000.

P. S.—The large number of patients already under treatment at our Institute justifies our Board in saying to our stockholders that a quarterly dividend of not less than 3 per cent. will be declared, payable on the coming 1st of July.

From the "Headquarters" of another "—— —— Cure Co." comes the following letter:

DEAR SIR: You are doubtless aware of the wonderful success that Dr. Keeley has had with his famous Gold Cure for Opium, Morphine, Tobacco, and Liquor habits, which is without a doubt the most wonderful discovery of the age.

Dr. Keeley, within the last few years, has amassed an immense fortune through this safely guarded secret, but we have now decided to give to reputable physicians only the benefit of long research and careful study, that they may be as successful in benefiting humanity as Dr. Keeley has been, for we now offer you a complete full formula of the famous Chloride of Gold Cure and at a moderate sum. Our idea in charging a price for this formula is to prevent its falling into the hands of unreliable practitioners and others who might use it to the detriment of humanity rather than a benefit, while at the same time we have endeavored to make the price so very reasonable for so very valuable a secret, that it is within the reach of all reputable physicians.

By this plan the number of patients treated will be infinitely increased, as there are thousands who would take advantage of this treatment, but will not face the publicity of treatment at an institute; such would consider it a Godsend to be treated privately at home by their own physicians. We expect the returns from the number of patients cured to be ample compensation, it being an acknowledged fact that the number of patients cured by the Chloride of Gold treatment is about 99 per cent.; as figures can't lie, you can readily see that much of the talk against this famous remedy has been made by people jealous of the success of others.

For the good of suffering humanity, we want this formula to be used only by physicians of good repute, and as we know you to be such, we take pleasure in offering you the formula for the famous Chloride of Gold Cure for one hundred ($100.00) dollars cash, and a royalty of five ($5.00) dollars for each patient cured by the use of Chloride of Gold during two years from date of acceptance of contract.

We bind you in no way, more than the signing of the enclosed simple contract, depending upon your known good character for the fulfilment of the same.

There is not only a fortune within your grasp, but an opportunity to make yourself an additional blessing to humanity.

Should you desire an exclusive territory, we can make arrangements for the same, but if you don't

wish to take advantage of this considerate offer, kindly let us know at once, that we may make other arrangements.

Trusting you will give this your earliest attention, we are,

Fraternally yours,

———— ———— ———— ————.

JAUNDICE.

ONE by one the distinctions that apparently separate jaundice into two forms have been dissipated. As long as it was contended that bilirubin, the coloring-matter of the bile, was not formed, but only separated in the liver, or that it could be formed elsewhere, and especially in the blood, the distinction between hematogenous and hepatogenous jaundice could be reasonably maintained. Now, however, that investigation has demonstrated the fact that bilirubin is created by the hepatic parenchyma out of materials brought to the liver by the blood, the distinction becomes invalid and only a hepatogenous form of jaundice can be recognized. It is admitted that hematoidin (which occurs in old blood-extravasations) and bilirubin are identical, but the former is never present in quantities large enough to occasion the manifestations of icterus. The absorption of hematoidin may be followed by increased production of biliary coloring-matter or by discoloration of the urine, but neither nor both of these conditions constitute jaundice.

The hepatogenous character of jaundice dependent upon evident obstruction of the biliary passages is capable of ready explanation. Bile is secreted under blood-pressure so low that but little diminution of the pressure or but little resistance to the discharge of bile is necessary to bring about resorption, the pigment being deposited in the various textures of the body and giving rise to jaundice. The difficulty was encountered in endeavoring to explain the mechanism of the jaundice that occurs, for instance, in acute yellow atrophy of the liver, in phosphorus-poisoning, in yellow fever, in so-called Weil's disease, and in other constitutional affections. In these no cause of biliary obstruction was apparent, and, in the absence of other recognizable cause, the jaundice was dubbed hematogenous. It now appears, however, that even in these the jaundice is actually obstructive. By careful experiments carried on with wonderful persistence for a long period of years, STADELMANN (*Der Icterus und seine verschiedene Formen*, etc., FERD. ENKE, Stuttgart, 1891) has succeeded in demonstrating that in many of the conditions in which jaundice exists without apparent obstruction there is really a catarrhal condition of the ultimate biliary radicles, so that the process is one of resorption, and hence hepatogenous.

Under certain conditions, especially such as are attended with disintegration of the blood and hemoglobinemia and hemoglobinuria, it may happen that the biliary coloring-matter is secreted in excess, a state known as polychromia or pleiochromia resulting, in consequence of which jaundice may develop. The mechanism in these cases is, as in the others, really hepatogenous or resorptive. If bile is secreted in excess the condition is known as polycholia. This, however, is not necessarily attended with jaundice.

Some of the symptoms associated with jaundice are dependent upon the absence of bile from the intestine. Among these are the deficient peristalsis and constipation; the fermentative changes in the intestinal contents, which, in consequence, are more than usually offensive in odor and which sometimes occasion diarrhea; the stools are pale in a degree proportionate to the completeness of the interference with the entrance of bile into the intestine. Other symptoms, like the depression of the temperature, the slowing of the heart, the itching of the skin, are attributable to the presence of the biliary acids in the circulation. In the cases in which more profound and especially cerebral symptoms are present, these may be ascribed to the primary factor in the development of the jaundice, be that infection or intoxication.

SELECTIONS.

STATE AID FOR THE PAN-AMERICAN MEDICAL CONGRESS.

IN the previous issue of the *Medical Record* will be found the circular of information of the Pan-American Medical Congress, issued March 17th, which we advise all our readers not only to peruse but also to keep for reference. If they do not keep it the chances are that, as the time for the meeting approaches, they will wish to recall some of the provisions there laid down, and then they will remember our advice and wish they had acted upon it.

As is there stated, the Congress has been incorporated under the laws of the State of Ohio. This we cannot but regard as a very wise and useful measure, although we believe the American Medical Association has existed for a number of years without having been made a corporate body. The incorporation was at the instance of

a well-known statesman, who recognized the public and political (not partisan) importance of such a drawing together of men of science from the two Americas, and who believed that the general Government would aid the undertaking in a substantial way were there a body corporate legally empowered to receive and disburse money.

Concerning the propriety of Congress making an appropriation to meet the needs of this meeting there can be, it seems to us, no question. It is an unfortunate fact that the Southern Republics and ourselves have been too great strangers to each other. We are of different races, and hitherto the only bond of union between us was that of a common sentiment in favor of liberty—an abstract idea, and one good for orators to declaim about, but really a pretty fragile bond to unite two such dissimilar peoples. The only way in which true friendship and mutual respect and liking can be promoted between the different nations of this continent is by mutual exchange of visits and consequent personal contact of the individual members of these nations. Nothing is so likely to bring about such acquaintance and promote reciprocal good feeling as a Congress of this kind, where all meet on the neutral ground of science, political animosities and social prejudices being laid aside and forgotten. It will not only benefit medicine, but it will directly benefit this whole country, and every other country in America which may send delegates to Washington.

It is, therefore, no more than just that the National Congress should aid the physicians who have undertaken this work. We should be in a condition to receive our guests in a becoming manner and to do them honor. As is seen in the regulations, the foreign members are to be charged no fee for registration, the total expense falling upon members residing in this country. It cannot therefore be said that the physicians in the United States are seeking to throw the entire burden upon the country. But as the nation will benefit by the holding of this Congress in 1893, it is but right and just that it should also contribute to make the Congress a success in every way, financially and socially, as well as scientifically.—*The Medical Record.*

DRUG MANUFACTURERS AS MEDICAL TEACHERS.

There is a legitimate field for manufacturing pharmacy, and with regard to it we have naught but words of praise. It is legitimate, it is necessary, that there shall be special workers to supply in the purest quality, and in the best forms, the substances which clinical and scientific research have shown to be useful in the management of disease. But these substances must wait the demand for them. For a manufacturer to attempt to create a fictitious demand for his products by assuming the rôle of medical instructor, is an insult to the profession and a special insult to each individual practitioner to whom he sends his circular. As we see, such men do not hesitate to manufacture explanations of pathological conditions which will apparently favor the use of their remedies.

How absurd it is for men engaged in commercial pursuits to attempt to solve the great and intricate problems of medicine, and how criminal it is to permit the statements of such interested parties to have the slightest weight in deciding questions of treatment.

These are the firms who send drummers out to assist physicians in their work. There is nothing more aggravating than the representative from such houses. He is frequently a doctor who has failed in his own profession, or who has not yet entered upon it, or else a drug clerk, or a man who has already proven himself successful in selling new lines of stoves, or boots and shoes. And yet these very men attempt to instruct medical men on physiological and pathological points, and means of treatment, when they have once succeeded in forcing themselves upon their attention.—*Journ. Am. Med. Assoc.*

CORRESPONDENCE.

NEW YORK.

Looking back over the work of the medical societies here during the past winter, I recall the fact that the important subject of urinary analysis has received attention in two important discussions. The first occurred before the Post-graduate Clinical Society in the early part of the season; the second took place only a few days ago at the last stated meeting of the Academy of Medicine.

On the former occasion, the discussion was opened with an elaborate paper by Dr. W. H. Porter, giving extensive original studies in physiologic chemistry. The general opinion expressed by those who followed in the discussion, was that it was unsafe to look lightly upon the occurrence of albuminuria, for, while admitting that this condition was produced by extremes of heat and cold, and by various derangements of the circulatory system, it should ordinarily be looked upon as a "danger signal."

Granular casts, according to Dr. F. R. Sturgis, mean granular degeneration not only in the epithelium, but in the kidney. When the training of athletes was less thoroughly understood than now, it was not uncommon to find numerous hyaline casts in the urine of those undergoing the training, until they had become inured to its hardships, yet this was apparently only a very evanescent condition, and left no subsequent traces of its presence.

Dr. C. L. Dana had found the urine of neurasthenics usually voided in large quantities, it had a low specific gravity, and contained an increased proportion of the earthy phosphates. He had carefully studied the fluctuations in the quantity of chlorides present in cases of pneumonia, and while he acknowledged their general relation to the inflammatory process, he thought the other clinical phenomena much more trustworthy guides.

Having read and heard so much about the value of the gonococcus as a means of differential diagnosis between a simple and a specific urethritis, I was surprised to hear such eminent men as Dr. R. W. Taylor, Dr. F. R. Sturgis, and Dr. F. Ferguson unite in denying that this organism had any such value; and they argued in support of their position, that five other microörganisms had been found present in the gonorrheal discharge, and careful experiments had

shown that in the urethræ of children or of those who had never had gonorrhea, the so-called gonococcus was present. In short, they considered that the position assumed by Neisser and his followers, that the presence of this organism in a discharge brands it as of gonorrheal origin, was likely to prove unjust and injurious to many innocent persons, and would eventually place the medical profession in a ridiculous light.

In the recent meeting at the Academy, Dr. Andrew H. Smith spoke of a reaction between ether and urine, which he thought was entirely new and opened up a promising field for study. He had accidentally observed the reaction in the course of some experiments that he had made with the object of differentiating serum-albumin from other forms of albumin in the urine. When sulphuric ether is very thoroughly mixed in a test-tube with most specimens of urine, the whole mass becomes foamy, and if the tube be well corked, and set aside for some hours, it will be found that the tube contains a firm, opalescent, gelatinous plug. From the fact that this reaction is usually absent only in the urine of persons who have been fasting for many hours or who have been on a restricted diet, such as a milk-diet, it seemed probable that this material separated from the urine by the ether represented the excess of proteids taken into the blood. If the urine be albuminous, the reaction with ether is still obtained, provided the person be on a liberal diet; but if not, it will only appear when the albumin is removed by heat and nitric acid, and the filtrate tested with the ether. Dr. Smith suggested possible explanation, founded on the knowledge obtained by this reaction, of the occurrence of anuria after prolonged etherization, viz., that if the operation be performed a number of hours after a meal, or, in other words, at a time when the blood contains a maximum quantity of the products of digestion, the ether, as it is excreted from the kidneys, may cause a plugging up of the uriniferous tubules with this gelatinous material.

Another important discussion was that before the Section on Pediatrics of the Academy, on the Therapeutics of Diphtheria. It requires almost as much patience and forbearance to attend a discussion nowadays on this subject as to attend one on the treatment of tuberculosis, but nevertheless your correspondent felt fully repaid for his effort on this occasion, for besides hearing an expression of opinion from a number of those whose experience and judgment add weight to what they say, there were a few little kernels garnered from the usual amount of chaff that seemed, in the writer's humble opinion, to have a positive practical value.

Dr. Joseph E. Winters advocated irrigation with large quantities of *weak* disinfectant solutions, special care being taken to avoid irritating the adjacent tissues, and so rendering them vulnerable to the onslaught of the Loeffler bacillus, and also to carry out the washing in such a manner as to cause the minimum amount of discomfort and exhaustion to the patient. His method consists in using a Davidson syringe with a nasal tip, and injecting, preferably, in most cases, through the nose, a saturated solution of boric acid or a ten per cent. solution of hydrogen dioxide, from a half to one pint of solution being used each time. In very severe cases, when it seemed advisable to wash out the mouth, he attached to the syringe a rubber tube or soft catheter, which was then passed as far back as the last molar tooth. The patient could be placed on the side, and the bedding be protected with a rubber cloth, arranged so as to carry off the fluid. He believed also in inhalation of steam, and for this purpose nothing was better than the ordinary Arnold steam-sterilizer with the croup-kettle attachment; but whatever form of kettle be employed, it is absolutely necessary that two or three feet of large rubber *hose* be used to conduct the steam from the kettle to the patient. He recommended adding two drams of oil of eucalyptus and two ounces of turpentine to the water in the kettle. He laid great stress on the advantage to be derived from the inhalation of the fumes of burning sulphur, and stated that it relieved the inflammatory swelling, the dryness of the throat, and the painful deglutition, much better than did either steam or cocaine. One remarkable feature of this treatment is that the patient often experiences great relief when the air of the sick-chamber is so laden with sulphurous acid as to make it unbearable for the attendants.

Dr. H. D. Chapin spoke of the obstacles that are encountered in endeavoring to carry out proper disinfection and quarantine in limited apartments, and he said that almost incalculable good would follow the establishment by the municipal authorities of stations or places of refuge for the well children in families stricken with the disease. He advised that the attendant should have an outer garment to wear only in the sick-room, that all rags soiled with secretions should be burned, and that after the termination of the case, pillows, comforters, and like articles, should be thoroughly beaten on the roof, and exposed for many hours to the sunlight and fresh air. Floors and ceilings should be washed with a 1 : 1000 solution of corrosive sublimate, and papered walls wiped down with stale bread-crumbs.

Dr. C. W. Allen called attention to the very prudent practice in vogue in Europe, of interposing a glass plate between the physician's face and the patient while local applications or examinations are being made, thus avoiding the lodgment of particles of secretion in the physician's eyes, or upon his face or beard, and so not only protecting him, but diminishing the chances of his carrying the disease to others.

Dr. L. Emmett Holt said that sick children were most commonly over-fed and over-stimulated. Milk, beef-juice, mutton-broth, wine-whey, oatmeal and barley gruels furnish a sufficiently varied dietary, and these articles are much less likely to disagree with the stomach than ice-cream or wine-jellies. When forced feeding becomes necessary, the rectum cannot be depended upon; it is better to use a soft-rubber catheter introduced through the nose and attached to a funnel.

Dr. Abraham Jacobi again declared his steadfast belief in the efficacy of the mercuric chloride treatment, and dwelt upon the importance of recognizing the first flutterings of the pulse that predict the occurrence of dangerous heart-failure unless the practitioner heeds the warning, and without delay resorts to the bold but judicious use of cardiac stimulants.

While the usual amount of good scientific work has been done in the Academy of Medicine this season, the even tenor of its way has been somewhat disturbed by murmuring and dissension. It began with an arraignment by Dr. R. W. Amidon, in a public letter, of the

methods pursued by the officers of the Academy, particularly in regard to the manner of conducting the discussions. He complained that to the announcement of the reading of an important paper, or the occurrence of a special discussion, were appended the names of several gentlemen who were to participate in the discussion, and that not only were so many members thus assigned to take certain parts in the discussion that there was practically no time left for others to join it, but usually the same gentlemen figured in this way for every important discussion in the branch with which they were especially identified. While anyone who is a constant attendant at the meetings of the Academy and of its Sections knows this to be true, the remedy is not so apparent, for the object of assigning certain members to certain topics is to prevent prolix and irrelevant discussion. It has certainly done away with much loose and ill-considered debate, but it has not disposed of irrelevant talk, as those invited to "open" the discussion come with papers already prepared, and deal with many points not directly bearing upon the subject in hand. There seems to be no doubt but that this plan, which has been in vogue for some years past, draws out a larger attendance and a more valuable discussion; but, on the other hand, it does not give a proper opportunity for the young blood to assert itself.

The present policy of the authorities is probably the wisest under the circumstances, namely, to continue to assign certain men to "open" the discussion, but to limit this number so as to give ample opportunity for others to take part. There have been other troubles, chiefly in regard to the increase in the annual dues, but this is hardly a matter of sufficient general interest to warrant a place here.

I recently heard an amusing incident illustrating the wonderful delicacy of a blind person's sense of touch. In a large dispensary patronized by many Italians, and consequently where those whose duty it is to take the money are constantly on the alert for counterfeits, an exceedingly clever counterfeit dime was accepted as genuine, and later on was given out in change to one of the dispensary physicians, who also failed to notice that it was a spurious coin. Curiously enough, however, when this physician handed out the dime to a blind paper-dealer, the latter instantly returned it with the remark, "It's no good;" and careful examination showed that the poor blind man was correct.

DETROIT.

The Coming Meeting of the American Medical Association—The City ready for its Visitors—The Michigan State Medical Society—The St. Mary's Hospital—The late Dr. C. B. Gilbert—A Single Fare to Detroit.

DETROIT, which was recently described by a New York medical journal as "a beautiful city of 100,000 inhabitants, situated on Lake Erie," is just now the cynosure of medical eyes. The city is beautiful enough—none more so—but its population is 250,000, and it is situated on the Detroit River, a broad, expansive strait, which connects Lake Erie with Lake St. Clair. It derives its present medical importance from the fact that early next month the American Medical Association will hold its annual meeting here. Visitors from the East and South will be much delighted with the appearance of our city in the month of June, for Detroit at this time of the year is an ideal summer residence. The capacious steamers that ply up and down the stately stream that flanks its southern boundary will, no doubt, during the evenings of the week of the meeting, be crowded with physicians, who will doubly appreciate the invigorating breezes and picturesque scenery after the toils of the day spent in the sections of the Association.

Everything is ready for the reception of our medical visitors. The Committee of Arrangements is jubilant with the prospects of success. "We have the ships, we have the men, and we have the money too." The ships will be used for excursion purposes, and it is hoped that every visitor will be given the opportunity of visiting one of the river-resorts and feasting on the chickens and frogs that flourish so bountifully hereabout. The men will be on hand in the sections of the Association. A full and complete program is assured. Indeed, the Detroit meeting will be an epoch-marking one for the Association. For the first time in its history two working sessions will be in force, and at these sessions papers will be read and demonstrations made by some of the most eminent and renowned men in the country. The American Medical Association will show itself in its highest and best form—as a congress of specialists bound together by fraternal and professional ties.

The Michigan State Medical Society held its twenty-seventh annual meeting in Flint, May 5th and 6th. The weather was exceptionally bad, and this somewhat affected the attendance. The Society, however, has an inherent vitality of its own that no such trivial cause as bad weather can depress. The sections were well represented and more real scientific work was accomplished than ever before in the history of the Society. The *Transactions* of the Michigan State Medical Society has been pronounced a credit to the State by so competent a judge of such matters as THE MEDICAL NEWS.

The St. Mary's Hospital, which has recently opened a new wing, has been benefited financially by the profits accruing from a flower-show, which was held last week.

The local profession has recently sustained a loss in the death of Dr. Caleb B. Gilbert. Dr. Gilbert was an able and successful practitioner, and a scholarly and refined gentleman. His "Metaphysics" will be long remembered.

The single fare, which has been secured from the railroads for delegates to the American Medical Association, ought to supply an economic motive—if that were needed—sufficient to induce Eastern physicians to visit Detroit. There are many other inducements, and it is hoped that not the least of these will be the sincere and hospitable welcome the profession wishes to extend to all its coming guests.

NEWS ITEMS.

Program of the Section on Surgery and Anatomy of the American Medical Association.—

Tuesday, June 7th.—Afternoon Session.

1. Address of the Chairman. "Surgery of the Gall-bladder and Ducts," by J. McFadden Gaston, Atlanta,

Ga. 2. "Obstruction of the Cystic Duct, with a Case," by W. H. Myers, Fort Wayne, Ind. 3. "Peritonitis from Gall-stones," by W. E. B. Davis, Rome, Ga. Discussion opened by A. Vander Veer, Albany, N. Y.; F. W. Ross, Toronto. 4. "Gunshot Wound of the Liver and Stomach; Laparotomy; Recovery," by James T. Jelks, Hot Springs, Ark. 5. "Eight Cases of Esophageal Stricture," by D. S. Campbell, Detroit.

Wednesday, June 8th.—Morning Session.

6. "Intestinal Obstruction," by Dudley P. Allen, Cleveland, O. 7. "Intestinal Obstruction and its Treatment," by H. H. Mudd, St. Louis, Mo. 8. "Comparative Test of Anastomotic Devices," by John D. S. Davis, Birmingham, Ala. 9. "A Clinical Contribution to the Operative Treatment of Acute Intestinal Obstruction," by Nicholas Senn, Chicago, Ill. Discussion opened by S. McMurtry, Louisville.

Afternoon Session.

10. The Comparative Methods of Inguinal and Rectal Colotomy," by J. M. Mathews, Louisville, Ky. 11. "Intestinal Lesions in Abdominal Surgery," by Joseph Price, Philadelphia, Pa. 12. "On the Treatment of Injuries of the Abdomen not requiring Surgical Operations," by J. Schenck, Mt. Carmel, Ill. 13. "Emergency Work in Abdominal Surgery," by Mordecai Price, Philadelphia, Pa. 14. "Herniæ: Operable and Inoperable," by T. H. Manley, New York, N. Y. 15. "A Few Points in the Management of Strangulated Hernia," by W. B. DeGarmo, New York, N. Y. 16. "Illustrations of Methods of Operating in Hernia," by H. O. Marcy, Boston, Mass.

Thursday, June 9th.—Morning Session.

17. "The Cremasteric Reflex in Varicocele," by T. A. McGraw, Detroit, Mich. 18. "Experimental Researches in the Implantation of the Ureters into the Rectum," by R. Harvey Reed, Mansfield, Ohio. 19. "Visceral Phlebotomy," by George Harley, London, Eng. 20. "Advances in Aseptic Surgery," by F. J. Thornbury, Buffalo, N. Y.

Afternoon Session.

21. "Operative Procedures at the Base of the Brain," by Ernest Laplace, Philadelphia, Pa. 22. "Gunshot Wounds of the Cerebrum," by C. E. Ruth, Muscatine, Ia. 23. "Air in the Veins," by Edward Martin, Philadelphia, Pa. 24. "Total Excision of the Lower Jaw for Malignant Disease," by C. B. Nancrede, Ann Arbor, Mich. 25. "Cosmetic Surgery of the Nose," by J. B. Roberts, Philadelphia, Pa. 26. "Notes on the Diagnosis and Treatment of Lepers," W. T. Corlett, Cleveland, O. 27. "The Treatment of Infected Wounds of the Extremities by Continuous Immersion," by F. Jenner Hodges, Anderson, Ind.

Friday, June 10th.—Morning Session.

28. "Neurectomy of Great Sciatic Nerve; Removal of Astragalus for Talipes Equino-varus; Removal of Salivary Calculus; Amputation of Scrotum and Prepuce for Abnormal Condition of the Skin," by R. Merill Ricketts, Cincinnati, O. 29. "Tracheotomy in Reference to Foreign Bodies in the Air-passages," by W. F. Westmoreland, Atlanta, Ga. 30. "Forced Respiration; Fell Method of Face-mask and Tracheotomy in Diphtheria; Report of Case," by George E. Fell, Buffalo, N. Y.

Afternoon Session.

31. "The Modern Treatment of Gonorrhea and its Complications," by J. J. Darby, Columbia, Ala. 32. "A Rational Treatment of Enlarged Prostate, founded upon its Pathology," by Ernest Laplace, Philadelphia, Pa. 33. "Methods of Examination of Diseases of the Joints," by W. R. Townsend. 34. "Treatment of Compound Fractures," by W. H. Myers, Fort Wayne, Ind. 35. "Diseases of the Knee-joint and Hip-joint," by J. C. LeGrand, Anneston, Ala. 36. "Amputations in the Light of Mechanical Science *versus* Prothetical Science, illustrated with artificial limbs," by S. L. McCurdy, Dennison, O. 37. "Antiseptic Physiological Surgery," by John L. Link, Terre Haute, Ind. 38. "The Radical Cure of Hydrocele, by a New Method," by H. O. Walker, Detroit, Mich.

Section of Ophthalmology of the American Medical Association.—The following is a list of the papers promised the Section of Ophthalmology of the American Medical Association, for the meeting at Detroit, June 7, 8, 9, and 10, 1892.

Dr. Dudley S. Reynolds: Gradation of Lenses. Dr. W. Cheatham: Some Peculiar Cases of Astigmatism. Dr. H. V. Würdemann: What May be Considered Normal Corneal Astigmatism, with Results from Keratometric Examination of One Hundred Emmetropic and One Hundred Ametropic Pairs of Eyes. Dr. B. Alexander Randall: A Study of the Eyes of Three Hundred and Fifty-seven Boys in the Penn Charter School, of Philadelphia, with Notes on the Examination of School Children. Dr. Edward Jackson: Latent Hyperopia. Dr. A. E. Prince: The Fourth Degree Prism in the Correction of Hyperphoria. Dr. George T. Stevens: On the Relations of the Motor Muscles of the Eyes to Certain Facial Expressions. Dr. E. J. Gardiner: On the Treatment of the Anomalies of the Ocular Muscles. Dr. C. J. Lundy: Eye-strain and its Relation to Functional Disorders of the Nervous System. Dr. Louis J. Lautenbach: What Rules Shall We Adopt in Prescribing Cylinders for the Relief of Asthenopia? Dr. J. A. White: Immature Cataract and the Best Method for Hastening Maturity. Dr. A. J. Ervin: Treatment of Incipient Cataract. Dr. H. Knapp: Method and Results of Simple Extraction. Dr. A. R. The Medical Guild of Misericordia is a society of medical men, practitioners, and medical students interested in the work of mercy for the sorrowing and suffering. The Guild comprises an order of brothers and associates—the former communicants of the Episcopal Church and the latter members of any Christian denomination. The Misericordia is designed to develop, so far as possible, the invaluable opportunities which exist for extending Christ's kingdom on earth through the aid of medical missionaries. Members of the Guild obligate themselves to engage in any or all of the above works whenever occasion offers, and to consider it their especial duty to watch for opportunities of so doing. In a word, the object of the organization is to impress upon and keep before the minds of its members the duty of doing works of mercy, both spiritual and corporal, whenever it is possible. Wherever there is suffering, there is our opportunity. The Misericordia is designed to promote the spirit that is suggested by the name, and that cannot be put into the form of absolute rules; at the same time it can be made an obligation on the part of its members to be on the lookout for occasions to exercise the virtue of mercy to all who are in suffering or affliction, for Christ's sake. It also aims to afford professional relief in urgent cases to the worthy poor. The Guild desires to have representatives in every city and town, and especially in mining regions, railroad centers, etc., so that in case of sudden and appalling disaster, like that in Johnstown, Pa., the work of relief may be intrusted to the care of members of the Guild, and speedy aid and comfort be thereby attained. It is a noble work, giving emphasis to the life of all medical men, who are so well known for charity the world over. Members of the Misericordia who are qualified practitioners of medicine are requested to offer their services to the clergymen of the parish in which they reside, to look after special cases, and at all times to be ready to give their services as the Church may have need of them; and also to take charge of any needy persons, not necessarily paupers, but such as may be unable to pay fees. When, through tempest, fire, famine, or pestilence, or from other causes, great suffering exists, the members of the Guild nearest to the afflicted community at once report to the proper authorities for duty, and notify, by telegraph or otherwise, the Provost of the Guild. Efforts will then be made at once to secure needed relief. There are no ceremonies in connection with the admission of brethren or associates. Suitable references are required from applicants, and these being satisfactory their names are added to the roll of members. The admission fee is one dollar and the yearly dues one dollar. Contributions to the general relief fund are urgently needed. For further information address W. Thornton Parker, M.D., Provost, P. O. Box 1405, Beverly, Mass.

The American Surgical Association will meet in Boston May 31, and June 1 and 2, 1892. The following preliminary program has been arranged:

Dr. John B. Roberts, of Philadelphia, will read a paper entitled "The Treatment of Uncomplicated Fractures of the Lower End of the Humerus and of the Base of the Radius;" Dr. John Homans, of Boston, a paper on "Fibroid Tumors of the Uterus;" Dr. W. T. Briggs, of Nashville, a paper entitled "Surgical Operations in Persons Suffering from Diseases Not Connected with That Necessitating the Operation, such as Chronic Malarial Poisoning, Diabetes, Organic Heart-disease, etc.;" Dr. N. P. Dandridge, of Cincinnati, a paper entitled "Surgery of the Tongue;" Dr. W. H. Carmalt, of New Haven, Conn., a paper entitled "Conditions Demanding Excision of the Globe of the Eye;" Dr. T. F. Prewitt, of St. Louis, a paper on "Ancient Contractures of the Hip- and Knee-joints;" Dr. A. T. Cabot, of Boston, a paper entitled "Report of Operations upon Spina Bifida and Encephalocele, with Remarks."

Dr. Cohen's Case of Excision of the Larynx.—We are informed that at the next meeting of the Philadelphia County Medical Society Dr. J. Solis-Cohen will exhibit a patient from whom he recently excised the larynx and first ring of the trachea, and that he will utilize the case in disproval of some recent theories as to the manner in which the air of respiration receives its moisture.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment, provided that the request for reprints be noted by the author at the top of the manuscript. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,
1004 WALNUT STREET,
PHILADELPHIA.

ORIGINAL ARTICLES.

MISCONCEPTIONS AND MISNOMERS REVEALED BY MODERN GASTRIC RESEARCH.[1]

BY CHARLES G. STOCKTON, M.D.,
PROFESSOR OF MEDICINE, MEDICAL DEPARTMENT OF THE UNIVERSITY OF BUFFALO.

IT is now twenty years since Murchison described the condition that we still know as lithemia or latent gout. The late Dr. Fagge in England and Dr. Draper in this country have emphasized the importance of the disease, and the latter has given us a theory, which practice often seems to confirm, and which by many is believed to explain the relation that evidently exists between the character of the food taken and the lithemic state.

It is needless to recall the teaching that, owing to the facility with which the carbo-hydrates appropriate the lessened amount of oxygen going to the liver, there remains too little for the proper oxidation of the nitrogenous substances, the waste of which, as a result, passes into the circulation as uric acid. It will be remembered, that for this reason it is recommended that carbo-hydrates be withheld in cases of lithemia, and that the diet be restricted to nitrogenous substances. A complete withdrawal of carbo-hydrates is advised in aggravated cases. Now the more aggravated the case, according to this contention, the more it approaches typical gout; so that but a single step is needed to bring one to the position of advising an albuminoid diet in gout. Indeed, this is the present attitude of some adherents of the belief. From this position, viz., that meats constitute the proper diet for typical gout, let us retrace our steps to the question of a typical gout and the proper diet for it.

Gout, all will acknowledge, is common in England—not merely typical gout, with occasional severe paroxysms, with arthropathies and all the train—but gout manifesting itself in a variety of ways, as, for instance, in severe and persistent headaches; but in England, instead of allowing meats to these sufferers, they are placed upon an almost non-nitrogenous diet, and it is found that the more liberal the allowance of azotized substances the worse becomes the patient.

How is it that meats disagree with the gouty in England and agree in America? Observation teaches me that this difference is owing to a misconception; and that in the great majority of cases, in point of fact, an albuminoid diet is an improper diet in gout, whether it be typical or latent; but at the same time I am prepared to admit the signal benefit derived from prescribing this diet for many so-called lithemics in this country. In plainer language it is suggested that gout, although becoming more frequent, is still an uncommon affection in America; but, on the other hand, there is scarcely a disorder so often presenting itself to the city practitioner as that which so persistently has been called lithemia. Wherever mental strain, "nerve-tire," and imperfect oxygenation are seen, there is witnessed that group of phenomena that is here denominated lithemia. In all modesty let me aver that this is not gout, and that it is what Murchison described as *lithemia* may well be doubted.

All that make careful study of such cases must be impressed with the frequency of complaint as to the primary digestion, and, if the study be thorough, this association of digestive trouble with lithemia will be found invariable. Of course, this has not been overlooked, but the fault has been attributed to the liver. Now, habitual and painstaking examination of the stomach-contents alone is necessary to change one's belief in this matter, inconsistent as this may be with views that I held in 1885.[1]

It is maintained, then, that the condition in question is a toxemia of gastric origin, the result of wrong living, and particularly of wear and tear of the nervous system, and not the atypical expression of a mysterious, hereditary disease with its joints, its tophi, its arteries, and its kidneys.

To Leube's method of gastric aspiration we owe most of our precise knowledge of disorders of digestion, and following its use it was but natural to expect a mass of conflicting ideas as to the nature of these disturbances. Yet from this indiscriminate mass we have now some well-assured facts. We know that the normal gastric chemistry is often perverted, and that fermentable substances are capable not only of interrupting their own proper digestion, but of interfering with the digestion of substances of other kinds, of throwing upon the

[1] Read at the seventh annual meeting of the Association of American Physicians, held in Washington, May 24, 25, and 26, 1892.

[1] "Nutrition in Lithemia," Trans. N. Y. State Medical Association, 1885.

liver the task of oxidizing materials but partly and wrongly prepared. Following this excessive demand for oxygen come imperfect assimilation, toxemia, uricacidemia, and lithuria (Gouley).

What then, is the natural indication? It would seem to be the correction of the primary digestion. Experience proves that this is not too great an assumption. Correct digestion and you correct the toxemia. For the reason that meats are not likely to ferment, the albuminoid diet often affords at least temporary relief in these cases—relief of digestion and relief of toxemia.

This appears to be a reasonable explanation of the contradictory opinions held as to the proper diet in so-called lithemia, and why the albuminoid diet has received so great support from the practitioners in this country as compared with that from those in England; but the albuminoid diet often fails in these cases—its adoption is followed in some by immediate aggravation of symptoms, and in others not until a certain lapse of time.

This is readily explained by the systematic study of the gastric contents, for it will be seen that those that are subject to hypo-hydrochloric acid secretion are unable to digest meats satisfactorily, and that these substances, in fact, not infrequently undergo a putrescent decomposition in the stomach, inducing varied disturbances; the exception is when sufficient hydrochloric acid is administered after the meal to make digestion possible.

When, on the other hand, there is hyper-hydrochloric acid secretion (which in the neurotic frequently occurs), the albuminoid diet often affords instant relief, because digestion becomes facilitated; the liver is no longer overtaxed and is better able to convert the proteid waste into urea, and thus the lithemia is diminished. This will not be overcome, however, unless the patient sufficiently exercises and thereby increases oxygenation; but there will be diminished alkalinity of the blood, heightened acidity of the urine, and alkalies will be required for relief.

Undoubtedly, those that suffer from the gouty diathesis become victims of lithiasis more readily than others, but their number is relatively so small that one can say that lithemia is an auto-infection occasioned by imperfect primary digestion, usually arising in the stomach; and the failure of this organ is the result of too feeble innervation in those whose lives are relatively sedentary and whose drafts upon the nervous system are so great as to induce appetites proportionately too large for the physical activity of the organism.

The treatment, to be satisfactory, should be based upon the systematic study of gastric digestion. To resort at once to alkalies or mineral acids is to begin at the wrong end; and to advise indiscriminately an albuminoid diet, while it frequently succeeds temporarily, cannot with safety be long continued and often fails either wholly or in part.

In point of nomenclature it is suggested that the terms lithemia (Murchison), uricemia (Flint), uricacidemia (Von Jaksch), are too limited, for while the uric acid is manifestly a notorious offender, there are doubtless other more subtle and less understood substances that often find their way from the alimentary canal into the circulation, to disturb function and injure structure of various parts. To describe these states the term auto-intoxication (Bouchard) is at least suggestive.

In view of the enthusiastic labors of the French in the inviting realm of gastric chemistry, we may reasonably expect a more exact knowledge of these forms of toxemia in the future. Meantime, clinical study demonstrates their existence and importance.

From my case-books I am prepared to report a sufficient number of instances to justify the statement that neurasthenia, vertigo, persistent headache, insomnia, muscular spasm, and epileptiform convulsions; that naso-pharyngeal catarrh, laryngitis, tracheo-bronchitis, and asthma; that Bouchard's nodules, some cases of so-called arthritis deformans, and other joint-troubles, not to mention a variety of minor conditions and those concerning which there is a reasonable doubt, depend upon gastro-intestinal toxemia. At any rate, so far as space will admit, I shall append the reports of the cases referred to—cases that proved manageable by treatment directed to the digestion, as guided by a study of the gastric contents, and which in most instances had long resisted other lines of treatment.

I am aware that some of these cases are open to criticism. It may be said of some that they were of reflex origin; of others, that additional factors were not excluded, and finally that the general conduct of the cases, rather than the special management, led to the improvement. In reply, it is advanced that all of these objections were considered and for the most part dismissed as untenable.

In 1889, Dr. Garland read before the Association of American Physicians an admirable paper on "Gastric Neurasthenia," in view of which and of the discussion that it provoked, I feel considerable diffidence in advancing the subject of gastric disorder as the cause of neurasthenia. Nevertheless, these cases exist, perhaps more often as the result of gastrectasis.

On this subject Champagnac, in a recent monograph published in Paris, concludes: "1. The coincidence of dilatation of the stomach and prolapse of the right kidney and neurasthenic disturbances is absolutely incontestable. 2. One may, by directing treatment toward the dilated stomach, cure the nervous symptoms that accompany and follow dilatation. 3. This treatment does not cause the dila-

tation to disappear, but prevents the auto-intoxication that is the cause of the neurasthenic symptoms. 4. Although the gastrectasia does not disappear entirely, the patient ceases to be nervous. 5. In the pathogenesis of neurasthenic disturbances we do not admit the theory of Glenard—enteroptosis—but that of Bouchard—the pathogenic importance of dilatation of the stomach."

While not maintaining that the stomach is always responsible for neurasthenia, yet with most of these observations I am in perfect accord, convinced by many such cases as those herewith reported, and including all except those numbered I, II, IV, V, XI, and XII.

Neurologists have long been alive to the importance of attending to the primary digestion in epilepsy. I report two of several cases of epileptiform convulsions that I have seen relieved by treatment of the stomach, and in none of these were dyspeptic symptoms complained of.

The first case is of unusual interest.

G. N., twelve years old, was the only daughter of healthy parents. A cousin of her father was epileptic; a cousin of her mother was insane. The family history was otherwise good. The patient had an enormous appetite, and no symptoms of indigestion save a coated tongue. She had never menstruated. The urine was normal. In September, 1890, during the night, she had her first seizure. There was tonic followed by clonic spasm, which was succeeded by a period of coma. There was no recollection of the attack. The seizures were repeated twice before January, 1891.

Examination showed no physical defect, save gastrectasis and slight hypermetropia (O. D. = 20/XVIII. O. S. = 20/XVIII).

The equilibrium of the ocular muscles was normal. The ophthalmoscope indicated emmetropia. Correcting glasses afforded no relief.

The voracious appetite led to an investigation of the digestive tract. On February 23, 1891, after a test meal, I withdrew the stomach-contents. There were found present berries taken the day before, bread taken eight hours before, an abundance of ropy mucus, and free hydrochloric acid. A restricted diet and lavage secured immediate relief. Treatment was continued until May. From this time the patient seemed perfectly well; the stomach was much smaller; the appetite was natural; and there were no convulsions. One year later the patient was reported well, with no return of her trouble.

The second case occurred in a young woman (Case I). I have seen men similarly affected and relieved.

As to naso-pharyngeal and tracheo-bronchial catarrh, associated with and frequently dependent upon gastric disturbances, the cases are so numerous that they no longer excite special interest. To Dr. F. Whitehill Hinkel I owe thanks for opportunity to study in this direction. One case only is reported, although the list might be made long.

Mr. L., a merchant, forty-five years old, had suffered from catarrh of the upper air-passages for years; he vomited a quantity of mucus each morning; he also had acne rosacea. Local treatment afforded relief, but not cure. Examination of the stomach contents revealed an excess of free hydrochloric acid, with pronounced gastric catarrh. Appropriate diet and treatment relieved all the symptoms. There was sufficient emphysema to keep up gastric congestion. Indiscretion in diet re-established the gastric disturbance, with a renewal of the trouble in the upper air-passages.

The well-known relation existing between asthma (Case IV) and the state of digestion forbids more than mention of the matter here, but the dyspnea attending certain cardiac disturbances in which there may be also incompetency of the kidneys is, to a great extent, dependent upon gastro-intestinal infection, as demonstrated by Huchard and his assistant, Tournier (*Le Bull. Médical*, No. 19, 1892).

As to the causation of headache, it would seem that we should ascribe a larger proportion of cases to the stomach. One is too likely to turn away from this inquiry after having heard that there are no gastric symptoms, when in fact some of the most intractable cases of indigestion conceal themselves behind symptoms referred to remote parts. This is well shown by Westphalen,[1] and also by my own cases reported (Cases II, III, V, VIII, and XV).

Similar statements apply to habitual insomnia (see Cases V, VI, VII, XV, and XVI), and also to grave and mild forms of anemia (see Cases X and XII), a matter that has the support of Pick,[2] of Nothnagel's clinic.

Of late, few subjects in medicine have attracted greater interest than the nature of certain arthropathies. The matter is introduced here because there is reason to believe that, since the joint-troubles of rheumatism, gout, gonorrhea, and scarlatina, not to mention more, depend upon special forms of toxemia, so may still other joint-troubles depend upon toxemiæ not yet so clearly specialized.

Dr. Edward Blake, of London (*Amer. Journal of the Med. Sciences*, 1892, No. 2), reports instances of rheumatoid arthritis depending among other things upon oral sepsis occasioned by a faulty plate of artificial teeth. I have seen a case relieved completely by removal of old fangs and correction of a disturbing plate.

Years ago, Bouchard directed attention to certain nodules appearing upon the phalangeal joints of the hands in victims of dilated stomach. The importance given this matter in Paris may be estimated by

[1] Berlin. klin. Wochenschrift, 1891, No. 37.
[2] Wiener klin. Wochenschrift, 1891, No. 50.

the discussion reported in *Le Bulletin Médical*, 1892, No. 23.

Certainly these joint-troubles are extremely common in chronic dyspeptics, and while they are sometimes found when no symptoms of indigestion are discovered, there is reason for the belief that in these cases the joint-affections depend upon gastric trouble that is past or unrevealed. Pseudo-rheumatisms of infectious origin are seen to be common when searched for, and not rarely, in my opinion, they are gastro-intestinal in source.

The following case is interesting in this connection:

Mrs. H., aged thirty-three years, had always suffered from languor, loss of flesh, and diminished power of endurance. Two years ago, she suffered from what was called an appendicitis. From this she was restored to her usual health. Her blood was found lacking 50 per cent. in hemoglobin. She complained that for years she had experienced fugitive pains in her joints, particularly in the knees, and for several months forced flexion of these joints had been attended with a sensation of crepitation, which not only could be felt, but heard at considerable distance. These joints were somewhat enlarged. Recently the joints of the upper extremities had become stiff, swollen, and moderately painful, especially when moved. The woman's appetite was excellent, and she stated that she had never had the slightest trouble with digestion, although her bowels were not active. The urine showed an abundance of calcium oxalate crystals, but was otherwise negative. Searching for the cause of her anemia, the stomach was found to be too large, and there was marked clapotage. Although vague, there was sufficient evidence of gastro-intestinal disturbance to justify investigation. Accordingly, lavage was practised three hours after a test-meal, and the stomach found to contain no food; but there was present lactic acid in considerable quantity. The intervals between the meals and the aspirations of the stomach were now progressively shortened, but the result was the same until at last, thirty minutes after eating a hearty luncheon, all the food was found present, with an abundance of lactic, but with no hydrochloric acid. It was now determined to administer hydrochloric acid; 1.50 grams of dilute acid, in divided doses, were given after each meal; and gastric faradization was employed.

Immediately thereafter, food was found present; the digestion was slow, but still no hydrochloric acid was discovered. The patient, however, was promptly relieved in every way; the pains ceased, the stiffness of joints disappeared, and there was the most surprising improvement in her appearance. She gained four pounds in weight, her color returned, the bowels became regular, and she declared that she had not felt so well in five years. This state continued for some weeks, but then elapsed a week without treatment, during which the patient had an experience that fatigued her mentally, and she reported that her symptoms had all returned; there were languor and depression of spirits; the joints were again painful and stiff. Naturally, I prophesied that her stomach would be found empty again, and upon examination this proved to be the case; moreover, the lactic acid that had disappeared was again present in quantity.

This case is still progressing and under treatment, but its history is certainly instructive in the highest degree.

A tabular statement of the examinations is introduced here for convenient study:

Date.	Period after meal.	State of stomach and its contents.	Lactic acid.	Hydrochloric acid.
Feb. 29	3 hours	Empty	Present	Absent
March 2	4 hours	"	Present	Absent
March 4	2 h. 30 m.	"	Present	Absent
March 8	2 hours	"	Present	Absent
March 12	30 min.	All food present undigested; general meal.	Present	Absent
March 14	1 hour	Practically empty. Prescribed hydrochloric acid and gastric faradization.	Present	Absent
March 16	1 h. 15 m.	Food present.	Present	Absent
March 19	1 h. 25 m.	Food present.	Present	Absent
March 21	1 h. 15 m.	Food all present. Feels much better. Joint-pains gone	Present	Absent
March 25	4 hours	Food all present. Is better.	Present	Absent
March 28	3 h. 30 m.	Much food present. Has not felt so well in years.	Absent	Absent
April 5	2 h. 30 m.	Food present.	Absent	Absent
April 7	2 hours	Food present.	Absent	Absent
April 25	3 h. 45 m.	Empty. Pain and swelling returned. Feels badly.	Present	Absent

What impresses me most is the frequency with which patients present themselves for relief of anemia, asthma, headache, insomnia, diarrhea, constipation, muddy skin, and irritable kidneys, who make little or no complaint of the stomach, and yet whose troubles arise primarily from the stomach, and who can be relieved by treatment directed to that organ only.

The relations existing between disturbances of the digestive tract and the chronic diseases of those great eliminative organs, the lungs, the liver, and the kidneys, have not received that attention that the future will declare to be imperative. Literature now bristles with contributions thus directed, and in appreciating that the microörganisms that invade our bodies are pathogenic in proportion to the toxines that they develop, we are coming to perceive that very many morbid states hitherto misconceived, and sometimes misnamed, are merely results of auto-intoxication; that the excretory organs that so generally fail and decay would not thus suffer but for the unnecessary strain imposed upon them through the mischief arising in the gastro-intestinal tract.

REPORT OF CASES.

CASE I.—Miss B., aged twenty-five years, had for many years been weak and listless, and had convulsive seizures of an epileptiform character. She had slight astigmatism, which was corrected without benefit to the general health. She complained chiefly of attacks of unconsciousness. Examination disclosed gastrectasia, with excess of hydrochloric acid, catarrh, and variable digestion. Treatment by lavage and the direct application of the interrupted current, with suitable diet and gastric medication, resulted in the disappearance of the convulsions and the restoration of the general health.

CASE II.—Miss R., aged twenty-one years, had severe, frequent, and persistent headache that nothing relieved. Examination of the stomach revealed decided gastrectasia, with hyper-hydrochloric acid secretion. Treatment by lavage and the direct interrupted current for several months, together with proper diet and but little medication, resulted in a cure.

CASE III.—Mrs. G., aged twenty-eight years, had aggravated headaches, vertical and occipital, for many months. Meeting people, conversation, or reading gave her great distress. She was intensely nervous and weak. The eyes had been properly examined and corrected. The pelvic organs were sound. She had tried many things in a search for relief, but without success. Disturbance of vision accompanied the headaches. She complained of slight dyspepsia. Examination disclosed the existence of a dilated stomach—the lower border reaching about four inches below the umbilicus—catarrh, hypo-hydrochloric acid secretion, slow digestion, fermentation, and constipation. Treatment by lavage and the direct interrupted current for some months brought about relief from the headaches and disturbed vision, with quite marked improvement in the general health. The lower border of the stomach rose to the level of the umbilicus, and the patient considers herself well.

CASE IV.—Miss N., aged thirty-three years, complained of flatulency, gastric distress, eructations, and attacks of dyspnea that she called asthma. These last were accompanied by regurgitation of mucus from the esophagus, and a mucous discharge from the trachea, lasting only two or three hours. The paroxysms were sometimes intense and accompanied with great circulatory disturbance. The pulse in the intervals was slow and hard, the left ventricle undergoing hypertrophy. There were also areas of superficial anesthesia. Examination of the stomach revealed gastric hypotony, hypo-hydrochloric acid secretion, and catarrh. Treatment by lavage, restricted diet, predigested foods, and assafetida resulted in cure. She has recently had a recurrence.

CASE V.—Captain B., aged forty-eight years, formerly a shipmaster, now an agent, from leading a sedentary life has suffered from insomnia, with headache and nervous irritability. He has had belching of gas and sour stomach. Examination revealed a somewhat dilated stomach, with slow digestion and fermentation. He was treated by means of lavage and gastric antiseptics. His insomnia was immediately relieved. He improved steadily and completed his recovery by a transatlantic voyage.

CASE VI.—Mr. W., aged fifty-five years, had gastrectasia with hyper-hydrochloric acid secretion and phosphaturia. He was reduced in flesh and strength, had cardiac palpitation, mental restlessness, persistent insomnia, gastric uneasiness, and melancholia with delusions. Treatment by lavage and the faradic current applied directly resulted in marked amelioration of the symptoms and great improvement in sleep. The man was under treatment for three months, after which he was able to return to business; and although not well, his mind was sound and he was every way much better.

CASE VII.—Mrs. W. A., aged thirty-six years, suffered from pain in the left hypochondrium, disturbed sleep, inability to sustain mental or physical effort, and debility. She has a wandering left kidney. She had gastric distress, with fermentation and eructations of gas, but no vomiting. The urine at first showed excess of acid, later an excess of phosphates. Examination of the stomach showed great irregularity in digestive strength and secretions, with extensive catarrh. Digestion was usually slow. There was hypotony. She was treated by means of lavage and the faradic current, sometimes the continuous current. Improvement in the general condition was in ratio to the improvement in the gastric state. She was discharged after four months, improved, but not cured.

CASE VIII.—Miss H. R., aged twenty-one years, has suffered for two years from general debility, occipital headache, depression of spirits, and inability to work. Upon two occasions she has spat blood. The case had been considered tuberculous. No bacilli were found in the sputum. She had few symptoms of gastric disturbance. Examination revealed extensive dilatation, with irregularity of the secretions. Treatment by lavage and gastric faradization was continued for six months, resulting, after a sojourn of two months in the mountains, in a complete cure. She gained fourteen pounds in weight, and particularly showed improvement in the nervous system and in her power of endurance.

CASE IX.—Miss D., aged eighteen years, a farmer's daughter, has suffered for three years from general neurasthenia with headache, fainting spells, and inability to exercise even slightly. She spent most of her time in bed and was despondent, fretful, and peevish. The urine contained an excess of lithic acid and lithates. The bowels were constipated; the skin discolored. The girl regurgitated food, belched gas, and had pyrosis and nausea. Examination showed the stomach to be slightly dilated, and usually with an excess of hydrochloric acid. Lavage was employed for several months, and occasionally the continuous current. She was placed upon an albuminoid diet and occasionally given predigested milk; later, the diet was made more general and tonics were administered. Her improvement began with the advance in her digestive power. After four months she was discharged much improved and has continued gaining during the past year.

CASE X.—Miss B. C., aged twenty-eight years,

suffered from depression of spirits, mental and physical prostration, and profound anemia (the blood contained only 40 per cent. of hemoglobin). She suffered from gastric distress. Examination showed the lower border of the stomach to be four inches below the umbilicus; there were fermentation and extensive gastric catarrh. She was treated by Dr. Allen A. Jones for five months by means of lavage and the faradic current at night. Her stomach returned to its normal size, and digestion became satisfactory. The patient was discharged, recovered, with a disappearance of the nervous symptoms.

CASE XI.—Mrs. D., aged forty years, complained of occipital headaches, with attacks of vomiting, that would last for several days, and were accompanied with great prostration. There was gastrectasis; the lower border of the stomach extended four inches below the umbilicus. There were some catarrh and hypotony (hydrochloric acid was deficient). The woman was treated by means of lavage and internal faradization for three months. There was great improvement in every way, which has continued since the cessation of treatment.

CASE XII.—Mrs. C. B. G., aged twenty-six years, suffers from weakness, anemia, bronzed skin, with occasional chills, followed by elevation of temperature, lasting for several days. She has moderate gastric dilatation and poor and slow digestion, with hypotony. There is an absence of hydrochloric acid and sometimes an excess of lactic and fatty acids. Treatment by lavage, faradization, hydrochloric acid and other digestants, and nux vomica and physostigma, was instituted. Great improvement followed. After two months the patient was sent to Florida and returned well.

CASE XIII.—Mrs. G. S., aged twenty-six years, manifested a condition of neurasthenia, with gastric pain, nausea, and gas. Examination revealed a great excess of hydrochloric acid, with slow digestion of carbo-hydrates. Treatment by diet and antacids, as governed by the examination of the stomach-contents, was adopted. The patient was discharged after six months and is now well, although not particularly strong.

CASE XIV.—Miss E. W., aged twenty-two years, who has a neurotic family history, complains of great fatigue, made worse by mental exertion. She also has headache, and complains of burning in the epigastrium. She was found to have most marked dilatation, with very slow digestion and great excess of hydrochloric acid and some catarrh. She has been under treatment for six months, and has improved, but is not well. She is benefited by strontium bromide and other gastric sedatives. The diet can be regulated only after examination of stomach-contents. The condition is improved by lavage.

CASE XV.—Mrs. S. S., aged twenty-five years, belongs to a family of neurotics, one sister being a complete wreck from neurasthenia. The patient suffers from weakness, insomnia, headache, inability to sustain efforts of any kind, and backache. She is disturbed by light and by sound. She has a stomach of irregular size, sometimes found two or three inches below the umbilicus, while sometimes it is of proper size. The gastric secretions are also irregular. Digestion is sometimes rapid, sometimes slow. After treatment by lavage, electricity, and rest, the improvement in the state of the stomach was rapid and evident, and this was followed by improvement in the general condition. She is now progressing favorably.

CASE XVI.—Miss S., aged forty-two years, has suffered from dyspepsia since she was twenty. She has had two attacks of "exhaustion." She has also had typhoid fever. For the past ten years she has suffered from neurasthenia, showing itself in insomnia, occipital headache, weakness of vision, cold hands and feet, inability to sustain mental or physical efforts, and constipation. Examination shows the stomach to be moderately dilated, digestion to be slow, and accompanied with fermentation and gas. Hydrochloric acid is absent. After treatment by lavage, electricity, diet, and purgatives for three months, the woman was discharged well.

THE TREATMENT OF TYPHOID FEVER BY COLD BATHS.[1]

BY GEORGE WILKINS, M.D.,
PROFESSOR OF MEDICAL JURISPRUDENCE AND LECTURER ON HISTOLOGY, MCGILL UNIVERSITY; PHYSICIAN TO THE MONTREAL GENERAL HOSPITAL.

ON looking over the proceedings of this Association since its commencement, I saw that, as yet, the cold-bath treatment of typhoid fever had not been brought prominently before it. This I considered a sufficient reason for now bringing up the subject on the small number of cases that I have had to report, and of eliciting the views of this Association on such an important subject.

The advantages of the application of cold water have been very ably treated of by Dr. Porcher, at our first meeting, but my success in the use of cold baths has so convinced me of their superiority, in suitable cases, over all other methods, that I feel it my duty to add my testimony to that of many others who have, with such forcible arguments in their favor, advocated this method of treatment.

I am quite well aware that many members of this Association are as ardent supporters of the use of the cold bath as I am; several I know have so expressed themselves at previous meetings, and they have had greater experience in its application; indeed, it was owing to the very enthusiastic manner in which Dr. J. C. Wilson spoke of it to me, and the recorded history of his cases that I saw at Philadelphia, that determined me to give it a trial.

I feel quite satisfied that, as a result of that trial, I have saved some lives that I fear I could not have saved with any other treatment. I form this opinion partly from the average mortality from the use of the

[1] Read at the meeting of the Association of American Physicians, held in Washington, D. C., May 24, 25, and 26, 1892.

other most successful methods of treatment, as well as from the individual characteristics of some of the very bad cases that yielded to the cold-bath treatment. The total number of cases upon which this paper is founded is thirty-nine,[1] with two deaths. Of this number, seventeen were under the care of my colleague, Dr. Stewart, who has kindly permitted me to make use of them, and who, I may say, is quite as warm an advocate of the baths as I am.

There are very few physicians, I think, who carry out this treatment properly, who would feel justified in relying upon any other, especially in serious cases, unless certain contra-indications are present. Yet we see that in England—which may justly be called the birthplace of the cold-bath treatment—there are very few physicians who systematically make use of it. It is over one hundred years since Currie so strongly advocated its use there. It evidently died with him, as we have no record of its continuance. As almost every medical student knows, it is to the teachings of Liebermeister, Ziemssen, and Brand, especially the latter, that we are indebted for its re-introduction into therapeutics.

Liebermeister suggested that written instructions should be given to the nurse, as follows: A bath is to be given if the temperature is 104° or above, between 7 P.M. and 11 P.M.; if 103° or above, between 12 M. and 3 A.M.; if 102° or above, between 4 A.M. and 7 A.M. He advises that the temperature be taken about every two hours in the night-time, and sometimes even more frequently. During the day-time he seldom orders the bath unless the temperature rises above 105°. In cases in which the cold bath fails to reduce the temperature, or in which contra-indications exist, he administers antipyretics.

Brand advises the bath to be given whenever the rectal temperature reaches 102.2°, without regard to the time of day. He advises placing the patient in water at a temperature of 68°, keeping him there for fifteen minutes, making cold applications to the head, and using friction over the body. At Lyons this treatment of typhoid fever seems very popular, both in hospital and private practice. Bouveret, one of the hospital staff there, suggests trying the bath with the water at a higher temperature, say from 80° to 85°, and, if that is not successful, using the colder bath of Brand. By this method of treatment, and the occasional use of antipyretics, he has been able to reduce the mortality to 7.3 per cent.

Dr. Hare, of Brisbane Hospital, who seems to have had a very large number of cases, by adhering strictly to Brand's rules, in one report of 1173 cases has had a mortality of 7.8 per cent.[1]

During the first six months in which I made use of the cold baths I adopted Liebermeister's method. Since then I have adhered to Brand's method, with slight modifications. In the first place, I very seldom keep the patient in the bath longer than ten or twelve minutes, and place him there only when the temperature in the mouth reaches 102.6°. Secondly, if the patient comes under my care late in the disease, or if there are any marked symptoms of weak heart, I place him in a bath of 80°, and lower the temperature with ice to 68°.

In the cases in which I make use of the bath I proceed as follows: With respect to hospital practice, as I very seldom have more than two or three patients at a time requiring bath-treatment, I have one bath-tub filled for each patient, the same water, as a rule, being good for twenty-four hours. The bath-tub is wheeled alongside the patient's bed and kept there, a rubber air-pillow being placed in it to support the patient's head. Ordinary bathing-trunks are placed on him, and in most cases he is lifted into the tub. It has so happened that we have had patients weighing over two hundred pounds requiring this treatment, and necessity has compelled us to allow them to assist in getting into the bath. Whilst in it, cold-water compresses are placed on, or the water is poured over, the head, and at the same time another assistant applies friction to the surface of the body. Sometimes, while in the bath or just before it, from half an ounce to an ounce of whiskey is given in either milk or water. The patient is kept in the water a length of time corresponding to the fall of the temperature, as after he is in the bath five minutes the temperature is taken. If the temperature falls rapidly, he is taken out as soon as that is observed.

In the thirty-ninth case, already referred to, the temperature, on one occasion, within the five minutes, fell from 103° to 97.4°. Of course, he was removed at once. In another case—that of a fat woman weighing over two hundred pounds—the cold bath seemed to have very little effect, even a bath of twenty minutes' duration; this she had several times, the temperature falling less than one degree, until after she had received eight or nine baths, when it fell two or more degrees on each occasion. This woman was one of the rare cases in which a patient seemed really to enjoy the bath treatment. Although the temperature in the early stage of the disease fell only a fraction of a degree, she always expressed herself as feeling much better.

When the patient is considered to have been sufficiently long in the bath, he is lifted out and placed on a dry blanket, and his trunks removed;

[1] The thirty-ninth case, which was fatal, occurred after I had commenced the preparation of this paper.

[1] Practitioner, March, 1891, p. 170.

he is covered up and left for half an hour, when he is wiped dry and his temperature taken. This is almost always found to be from two to four degrees below what it was previously to the bath. The exceptions to the rule are very rare; in only two cases of the thirty-nine considered in this paper did such a reduction fail to occur. Of this number twenty-one were treated by placing the patient in water at a temperature of 68°; in the other cases the temperature of the water was 80°, reduced to 68° whilst the patient was in the bath.

The immediate effect of the bath was an average reduction of temperature of 1° in one case; of about 2° in two cases; of between 2° and 3° in nine cases; of between 3° and 4° in twenty-six cases; and of over 4° in one case. The last case was one in which the patient came under my care with a badly damaged heart and a dicrotic pulse, on the sixteenth day of the fever. He had but seven baths, all of short duration. The pulse seemed to improve slightly, notwithstanding which he died of syncope on the seventh day after admission. In 95 per cent. of the occasions on which the bath was used, the pulse fell within half an hour after the patient was removed from the bath, sometimes only two or three beats, but usually more, on some occasions as many as eighteen beats.

Unfortunately, I have not been able to get a reliable record of the amount of sleep in most of the cases or of the amount of urine secreted; but, whether the patient slept or not, the almost universal rule was that he rested quietly when previously he had been restless; and, in those cases in which notes had been taken regarding sleep, it was found that in most of them there had been sound and refreshing sleep, probably of short duration, but always invigorating.

In those cases in which, according to the rules, the baths were stopped on account of the fever temperature not being sufficiently high to require bathing, the patients very rarely rested as well, notwithstanding that sponging with cold water was made use of. In the nurses' notes of the progress of these cases a common observation is: "Patient not resting quite so well," and it is also a point to which they have frequently drawn my attention.

Although the refreshing effects of the bath are usually present, it is very rare indeed to find any patients who like the treatment. They often object—sometimes very vigorously. That occurred twice last summer. One of the cases was that of a man whose temperature kept very high, requiring numerous baths. He had seventeen in three days. On one of these days the temperature was several times over 104°, so that he had eight baths during one space of twenty-four hours. On each occasion the temperature was brought down to between 100° and 101°. After fourteen out of the seventeen baths he had a refreshing sleep varying in time from half an hour to two hours and a half. Notwithstanding this, he commenced to object at about the fourteenth bath, and during the time that the seventeenth bath was given him he growled and complained so bitterly and with so much noise that I was obliged to order the bathing to be stopped and to substitute sponging. Even to this he objected. After the discontinuance, he still continued to improve. His temperature only touched normal on the nineteenth day after the last bath. During the whole of this time he was much more restless than while having the baths. Another patient, who was delirious, resisted the first bath so violently that it was not attempted again. Both of these cases did well.

The only fatal case that I have had so far, besides the one referred to in the earlier part of this paper, was that of a man twenty-one years of age, who was said to have been ill only four days previously to entering the hospital, but who must have been ill for a longer time. There was then found to be present double broncho-pneumonia with albuminuria. Both pulse and respiration were very rapid. Nervous symptoms early made their appearance. Twenty-four hours after admission the man was delirious, and twelve hours later subsultus tendinum was present. The temperature, which was 104.4°, was brought down to 103° by the bath, but rapidly rose again. The baths were repeated on seven different occasions during four days without much apparent relief. The patient died on the fourth day.

I have been rather skeptical about the possibility of aborting a case of typhoid fever. Even yet, I am not convinced that such a thing can be done, but in a family in which I had three other well-marked cases, during my absence from town one child—at that time the second case—became ill with fever, headache, diarrhea, etc. The father of the child, to whom I had related my success in the use of cold water in hospital practice, and as I had been contemplating its use in the first case, took upon himself the responsibility of putting into practice in his family the method of which I had been speaking to him. This he did with the consent of the physician temporarily in attendance. He adhered strictly to the rules of Brand, with the result of complete subsidence of the fever in seven days. The development of two other cases in the same family, all of which had been subjected to the same source of infection—well-water in a country place—considerably strengthened my suspicions of this so-called aborted case being also one of typhoid fever. The three other cases averaged about six weeks' illness each, although they all had baths—the one that had most baths having had two serious and prolonged relapses.

So far, the greatest number of baths that I have given any one patient is thirty-five. This was in the case of a child nine years old. The entire number were given within ten days. In one period of twenty-four hours eight baths were made use of. The child used to sleep tranquilly nearly the whole time between the baths, but when his temperature fell below the standard requiring them he was much more restless.

I have not yet adopted the routine of treating every case of typhoid fever by cold baths. During the period in which these thirty-nine cases were treated I had nine others of a mild type under my care, the temperature not being persistently high; these were successfully treated on the expectant plan. I am not yet convinced of the advisability of treating every case of typhoid fever with cold baths, although last summer I had one case that for the first fourteen days appeared to be one of the mildest type, and subsequently proved one of the most serious under my care, except that she ultimately recovered. I believe now that had I used the cold baths in her case the serious symptoms might have been averted. When they appeared it was with the contra-indications of the bath. The case was that of a girl, nineteen years of age, whose temperature for the first fourteen days never rose above 102.2°, the lowest limit requiring the bath. There were no indications of any serious disturbance of the digestive tract. Her general condition was remarkably good in every respect, until the appearance of an alarming hemorrhage on the fifteenth day. After this time the temperature rose considerably above the bath-limit, at times reaching 104°, being associated with a weak and rapid pulse, and also several subsequent alarming hemorrhages. With this condition it was now too late to commence the bath-treatment. Nervous symptoms subsequently became a prominent feature in her case. Paralysis of the pillars of the pharynx, paresis of both lower limbs, and loss of the deep reflexes were observed. In the eighth week her symptoms, in many respects, resembled the pareses following diphtheria. It was only after the tenth week of the fever that these symptoms began to improve. As already stated, it is more than possible that the cold-bath treatment in this at first mild case might have so modified the nutrition of the ulcerated patches as to have prevented the hemorrhages.

The question naturally arises, How is the tendency to hemorrhage affected by the cold bath?

Hare, to whom I have already referred, who has written a very instructive and now well-known article in the *Practitioner*, states that, in the large number of cases (1173) in which he made use of the cold bath, while the actual mortality from hemorrhage was somewhat less than that of those treated on the expectant plan, the occurrence of hemorrhage was "as frequent (though not more so) under the bath-treatment." The experience of most of the German authorities is somewhat more favorable, as with them the occurrence of hemorrhage has been less frequent. Theoretically, it seems to me that it ought to be so. We know that fever always interferes with the processes of nutrition and repair in all the organs of the body—in some it causes actual waste, while in others it simply modifies their functions. The capability to resist the bacillary invasion of the bacilli of typhoid fever and the consequent sloughing of portions of the affected areas in the bowel is seriously impaired by the high temperature. When we lower the temperature, although we do not destroy the bacilli, which may have been actively at work in the earlier stages of the disease, we place the affected areas of the bowel in a much better condition to resist the effects of extensive sloughing. When the nutritive processes are not embarrassed by the abnormal temperature, the defensive struggle of the tissues against the bacilli is more effectual, and the bacilli, although probably gaining ground during the first few days, do so only by a truly ulcerative process—*i. e.*, molecular necrosis—in which *vis medicatrix naturæ* manifests itself by protecting with granulation-tissue the elements in the immediate vicinity of the ulcer.

To put my meaning in fewer words: With continued high temperature we should expect larger sloughs, with exposure of vessels; with intermittent elevations of temperature the necrosis is molecular, and the vessels stand a better chance of being protected by granulation-tissue. The cold bath almost invariably reduces the temperature from two to four degrees; this reduction frequently means a normal temperature. In that case we produce an intermittent fever. True, this intermission is usually of but short duration, but the more perfectly intermittent we cause the fever to be, so far as temperature is concerned, the less likely are the secondary effects of the fever, which constitute the real danger, to make their appearance. Continued high temperature, as is well known, besides causing degenerative changes in the heart and voluntary muscles, affects also the parenchyma of the glandular organs.

Nor does the central nervous system escape being profoundly affected by these high temperatures. We have ample evidences of this by the continuous headache, stupor, delirium, and, what is of even greater significance than these, the blunted sensibility of the various reflex nerve-centers. In some of these conditions time is all-important. Two or three hours less of a high temperature constitute an enormous saving to the patient. We all know that three or four hours' duration of a temperature of, say, 104° or over, has a much more serious effect than a temperature of, say, two degrees lower lasting three or four times as long. Here we see the markedly beneficial effect

of the cold bath. Frequently have I seen a patient with a temperature of 104°, with a dull, heavy expression, dry and brown tongue, weak heart and rapid pulse, and with slightly increased frequency of respiration, after a bath of 68°, resting quietly in sound, natural sleep, with a temperature reduced to 99°, and a pulse nearly always reduced in frequency, often as many as fifteen beats, and also increased in volume. Of course, the temperature will rise again, sometimes shortly and at other times after a longer duration, but the patient has had an interval of rest that is of inestimable advantage to him. Now there is no other remedy with which I am acquainted that will produce such an improvement in all of the symptoms. True, many of the antipyretics will reduce the temperature quite as much as the bath, but none of them will do so as rapidly and as certainly. The use of all is attended with some more or less objectionable features.

My experience has been that almost invariably the patients sleep for a short time after the bath. If not sleeping, they are quietly resting. One of our graduates of this year, who had typhoid fever last January and was under the care of my colleague Dr. Stewart, was treated both with phenacetin and other antipyretic drugs and the cold baths, at different times, and is most enthusiastic in speaking of the soothing effect following the bath. Like most patients, he dreaded the bath on account of its immediate effect, but says that there is no comparison between the after-effects of the two methods of treatment. He says that phenacetin, whilst reducing the temperature sometimes as much as the bath, did not give as much relief, nor did he experience as much relief from restlessness and anxiety. He found the bath decidedly refreshing and invigorating.

It is a popular belief amongst the laity, in which I fear many physicians shared until very recent years, that the cold bath tends to produce mischief in the respiratory apparatus, *i. e.*, the patient will "take cold." As most of us now know, quite the reverse is the case. Liebermeister draws particular attention to his experience in this respect. With him, in the cold-bath treatment, the percentage of cases presenting respiratory complications was much less than in any other method of treatment, while *the mortality* among those with pulmonary complication was also much lower than usual. Dr. Hare's experience was still more favorable than that recorded by Liebermeister. Fatal cases occurred with him in only one-fourth of the number of those fatal under treatment by the so-called expectant method, which included cold sponging and the occasional administration of antipyretics. These different results may be accounted for by the slightly different methods of treatment. Hare followed strictly the rules laid down by Brand, whereas Liebermeister adhered to the method mentioned in the early part of this paper. In the commencement of my cold-bath treatment I followed the suggestions of Liebermeister, but since then I have adhered more closely to Brand's instructions, with apparently better success.

In the early part of last month a patient was brought into hospital under my care, apparently on about the eighteenth day of the disease, suffering from diarrhea and a slight cough. His tongue was very dry and brown; his pulse was weak and rapid; and he had broncho-pneumonia affecting both lungs; there was marked dulness behind in the left infra-scapular region; the urine was diminished in amount and contained a large proportion of albumin. I rather dreaded trying the bath-treatment, and for four days tried quinine, phenacetin, and salol, with free use of stimulants. Notwithstanding this, the temperature continued to rise, the urine to diminish in quantity, and the physical evidence of lung-complications to increase. The combination of these three symptoms, with the absence of cough corresponding to the extent of lesion, determined me to try the cold or rather cool bath. I had the patient placed in water at a temperature of 80° and reduced with ice to 68°. Whilst in the bath, friction was used. Placing him in the water at once started vigorous coughing, with free expectoration. His temperature fell to 99°, the pulse-rate to 88. This treatment was repeated every time the temperature rose to 102.4°, with the result that the amount of urine was increased in twenty-four hours from twelve ounces to twenty-four in the first twenty-four hours, and to thirty-eight on the following day—more than double what it had been during the previous six days he was in hospital. The albumin diminished in quantity. The lung-symptoms at once commenced to improve. Gradually the bronchi became emptied of the mucus and the air-vesicles cleared up rapidly. The tongue commenced to lose its glazed appearance. After the sixth bath the temperature kept below 102°, and within ten days he began to convalesce and is now well.

In this case during the four days that the patient was in the hospital before the bath-treatment was commenced, his temperature never went below 101.8°, nor was his pulse-rate below 100, although he was sponged every four hours. A detailed statement of the effect of the few baths he had may be of interest, and may be taken as an example of their effects in nearly all the other cases:

Before bath.	Temp.	Resp.	Pulse.	Duration of bath.	30 minutes after bath.		
					Temp.	Resp.	Pulse.
				min.			
April 11, 6 P.M.	103.4°	24	112	13	99°	28	88
8 P.M.	105.2	32	124	12	101	28	94
April 12, 11 A.M.	102.8	32	108	12	98.2	28	108
2 P.M.	103.8	34	124	10	100.2	32	108
6 P.M.	102.8	30	110	10	99	26	92
8 P.M.	103.0	28	110	11	98.3	24	90

During the following ten days the temperature kept below 102.4°, hence sponge-baths only were required. The temperature remained normal after the tenth day.

Whilst writing these notes (May 12th) I have convalescing a case of pneumonia treated only by cold baths. I may be excused mentioning it here, as I think it has a direct bearing on the benefits of the bath in high temperature from any cause.

The patient, a young man, came under my care two days after the initial rigor, and when I saw him first his temperature was over 104°. I will refer to the bath-treatment so far only as the fever, respiration, and pulse-rate are concerned.

Before bath.	Temp.	Resp.	Pulse.	Duration of bath.	30 minutes after bath.		
					Temp.	Resp.	Pulse.
				min.			
May 7, 2.30 P.M.	104.2°	32	100	12	99°	24	84
May 8, 9.30 A.M.	104	36	116	11	99.4	32	88
2 P.M.	104.8	40	100	12	100.5	26	88
6 P.M.	104	28	120	12	99.8	28	78
May 9, 10.15 A.M.	104	30	100	12	99.8	26	90
May 10, 6 P.M.	104	32	92	13	98	26	78

No more baths were given after this, as the crisis occurred on the following morning, with improvement in all the physical signs.

To quite understand the rationale of these events we must consider the cause of the respiratory troubles in typhoid fever. This is not very far to seek in the weak heart, which may produce very varied conditions. That the central nervous system is affected we have ample evidence. Amongst others, the activity of the vasomotor system is impaired. The degenerating heart-muscle pumps blood with enfeebled power into both systems. The impaired vasomotor activity manifests itself in the lungs in a two-fold manner. It affects both the bronchial and pulmonary vessels; the blood circulates slowly in the relaxed vessels. In the bronchial arteries we have evidence of this sluggish movement of the blood in the catarrhal condition of the bronchi and bronchioles, as a result of which they may ultimately become choked up. A blunted sensibility of the nervous system, with probably weak respiratory muscles, prevents mucus being expectorated, with a resulting collapse of that portion of the lung; or, the right side of the heart may be at fault, with a resulting congested state of the branches of the pulmonary vessels in the alveoli of the lungs, developing probably a fatal pneumonia. Usually, both sides of the heart are involved in the respiratory troubles, producing a more or less complete broncho-pneumonia. Now, as was shown in the case I have just related, and in many somewhat similar cases, the bath, instead of being injurious, is especially suitable. The contact with the cold water invariably produces deep respirations, thus avoiding the tendency to collapse of the lung.

Coughing is induced, the mucous plugs are expectorated, and the over-strained heart is relieved; and, what is more, the heart itself is directly stimulated. These facts I consider as of great importance in showing how closely the nerve-centers are related to many of the more serious symptoms present in the fever. There can be no doubt but that high temperatures alone seriously impair the nutrition of the centers; hence the serious complication just named.

That the cold bath has a local cooling effect is self-evident. That local effect is soon transmitted to the internal organs, as after the first effect of contact with the cold medium the vessels that were contracted become widely dilated, and expose much more of the blood to the cooling influence of the water. The effect of the application of the cold water to the surface of the body is observed in another way. As is well known to every one, as just stated, it causes contraction of the bloodvessels. This means a temporary increase of the blood-pressure, and thus a stimulation of the heart to increased work. As a consequence, the blood that has been lazily coursing through the internal organs, crowding the venous system and interfering with their functions, is forced to move on, thus relieving the tendency to congestion. This, I think there can be little doubt, accounts for the increase of the urinary secretion almost always observed in these cases, as was the case also in the one just related. I think we have here a very plausible explanation of the continued fall of temperature after removal from the bath. The diminished secretion of urine during the febrile state must mean retention of poisonous material in the blood, as the result of the bacillary invasion. A restoration of this secretion is probably, therefore, one of the factors in the elimination of the toxines produced by the bacilli. That typhoid fever is a complex febrile state is demonstrated by the range of temperature. In the earlier stages we have the regular rise produced by the bacillary growth, followed by the irregular temperatures, the result of absorption of the products of the bacilli, *i. e.*, the toxines produced by the suppurative micrococci that accumulate to a greater extent in proportion to the diminished secretion of urine.

With respect to contra-indications, the most important are those accidents that may arise in the course of the disease, and which require rest as one of the means of treatment. This applies to hemorrhage from the bowels and also peritonitis. A very weak heart with a dicrotic pulse will require great

caution. If there has been long-continued high temperature there is almost certain to be a degenerative condition of the muscular structure of the heart, and consequently the sudden determination of blood to that organ as the result of the first contact with the water may so embarrass it as to cause serious or alarming symptoms. These occurred in one case that, however, did well ultimately, the patient becoming unconscious in the bath, but on immediate removal being much improved by it. This patient had a number of baths subsequently, with no unpleasant results.

This paper really represents a mortality of two out of forty eight cases, of which number thirty-nine had been treated by cold baths; the remaining nine were of a milder type than those treated by the bath, except the one case in which there were hemorrhages, to which I have referred at length.

I have not attempted to go into statistics, as the number of cases that I have had is not sufficiently large to be of service, nor have I attempted to give a systematic treatment of typhoid fever. I simply wish to add my testimony to that of the many other members of this Association who on previous occasions have incidentally in their discussions advocated the employment of the cold bath or referred to its advantages.

It is a fact that cannot be denied that in about 90 per cent. of conditions of pyrexia, in which the cold bath is systematically used, it will reduce the temperature, lessen the pulse-rate and frequency of respiration, and increase the daily amount of urine secreted, besides promoting, if not actually causing, sleep.

I venture to submit that there is no other remedy in our materia medica, the use of which will as surely and as quickly yield all of these favorable and most desirable results.

MEDICAL PROGRESS.

Diabetes Mellitus of Unusual Course.—HOLSTI (*Zeitschr. f. klin. Medicin*, 1892, xx, 3, p. 272) has reported the case of a man, forty-one years old, who, two months after an attack of influenza, had a recurrence of pain in the arms and legs, and one month later suddenly began to experience great thirst, at the same time passing large quantities of urine. The urine examined a month later responded to tests for sugar. Thirty-six pounds had been lost in weight. The right lower extremity was edematous. At a subsequent examination, the urine had a specific gravity of 1039 and contained 8.8 per cent. of sugar. More than five pints was passed in twenty-four hours. The patient was directed to partake only of meat, cheese, and eggs, and to drink only carbonated waters. In the course of a few days, sugar could not be detected in the urine, although the specific gravity was yet high. The sugar did not again appear, and the specific gravity gradually became lower, although ordinary diet was again resumed.

The Therapeutic Value of Suppuration.—FOCHIER has observed that in some cases of puerperal infection, when there is no important appreciable lesion, a sudden amelioration not rarely takes place coincidently with the appearance of a focus of suppuration in the iliac fossa, in the breast, in the subcutaneous cellular tissue, or about a joint. The thought suggested itself that in suitable cases the establishment of suppuration by the subcutaneous injection of essence of turpentine might be a rational procedure; and in a number of cases, successful results were by this means obtained. Governed by the same principle, LEPINE and DIEULAFOY each employed the injections in a desperate case of pneumonia, with a fortunate termination. About fifteen minims were injected in each situation selected. Suppuration took place in the course of a few days, but it was unattended with elevation of temperature, and the pus was aseptic. —*L'Union Médicale*, No. 39, 1892, p. 465.

Scarlatiniform Erythema.—ROSSIGNEUX (*Lyon Méd.*, March 27, 1892) reports a case in which, after counter-irritation of the chest in the treatment of bronchitis, a diffuse red rash appeared, with constitutional symptoms, mild angina and fever, followed in five days by desquamation. A year later, after an application of tincture of iodine to the chest, a similar attack occurred. After the lapse of another year, symptoms of irritation appeared in the left eye, the lid became swollen, and an intense, generalized red rash, accompanied by pruritus, developed, together with malaise and headache and swelling of the tonsils. In the course of a few days desquamation took place. The condition is considered as neither scarlatina or exfoliative dermatitis, but a scarlatiniform erythema probably of rheumatic origin.—*Rev. Gén. de Clin. et de Thér.*, 1892, No. 14, p. 216.

General Symptoms from Accumulations of Cerumen in the Auditory Canal.—AITKEN (*British Medical Journal*, No. 1630, p. 652) records three interesting observations in which general symptoms disappeared after the removal of accumulations of cerumen in the auditory canal. In a little girl, eight years of age, with incessant cough, bad nights, frequent night-terrors, loss of appetite, and emaciation, without physical signs of pulmonary disease, one of the ears was found blocked with wax. In a man, eighty-one years of age, with restlessness, tremor, derangement of digestion, and deafness, the ears were found filled with large masses of hardened wax. A girl, eleven years of age, with a tuberculous family history, presented elevation of temperature, frequency and irregularity of pulse, but without other signs of organic disease. An accumulation of wax was found in the ear.

Sudden Death in Pleurisy without Effusion.—TALAMON (*La Médecine Moderne*, No. 15, 1892, p. 217) records two cases of sudden death in the course of chronic adhesive pleurisy. He maintains that while sudden death is to be feared when an effusion exists, it may take place under other conditions, and is usually dependent upon thrombosis of the pulmonary artery, in conjunction with deranged action of the right heart.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,
1004 WALNUT STREET,
PHILADELPHIA.

Subscription Price, Including Postage in North America.

PER ANNUM, IN ADVANCE . . . . . $4.00.
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,

PHILADELPHIA.

SATURDAY, MAY 28, 1892.

KEELEY, TALMAGE & CO. (UNLIMITED), DEALERS IN MEDICO-RELIGIOUS HUMBUG.

THERE have been many enemies of modern popular Christianity, and some have inflicted upon it powerful and grievous injury, but when the whole history shall have been written, it will be found that by no agency has it been so vitally wounded as by its present-day unholy alliance with quackery. An ancient libel upon medicine has been crystallized into an old Latin proverb, meaning that two out of every three physicians are atheists. This, of course, is a lie, because no body of men is made up of more reverent and—in a true and essential sense—religious minds, than is the medical profession.

It is a lie—but a certain class of modern religious clowns and caricatures are trying their best to make it true. If the simile may be pardoned, nothing would more effectually make a scientific mind vomit up the whole good dinner of religion than the nauseating stench of flatus so freely vented by these pseudo-religious demagogues.

For instance, we read (*New York Herald*, May 16th) as follows:

> The REV. DR. T. DE WITT TALMAGE stood on the platform of the Brooklyn Tabernacle last night with DR. LESLIE E. KEELEY, of Dwight, Ill., and helped to advertise that gentleman's institutions for the cure of drunkenness.
>
> Several members of the congregation walked out of the church before the meeting was over.
>
> DR. KEELEY, accompanied by his wife, went to Brooklyn in the afternoon, and after dining with DR. TALMAGE went to the Tabernacle. REV. DR. I. K. FUNK offered prayer, in which he called down the blessings of heaven on DR. KEELEY, who, he said, was "the glory of the nineteenth century." The congregation sang "Hold the Fort," and then DR. TALMAGE introduced the lecturer, who, he said, would live on in centuries, and would eventually drive drunkenness and morphine off the face of the earth.
>
> The lecture itself was uninteresting, and at its close DR. TALMAGE announced that he would ask DR. KEELEY a few questions that had been given to him by prominent clergymen and physicians. He read the questions from a slip of paper which he held over a hymn-book. Here are some of them:
>
> Q. Now, DR. KEELEY, tell this assembled multitude if there are any poisons in your cure.—A. There is nothing deleterious, inimical, or hurtful in my cure. A child could drink a barrel of it and it would not do any harm.
>
> Q. Does the temptation to strong drink pass away after a person has been through your treatment?—A. A man never has any desire to drink again after being treated by me. My cure destroys all desire. If he goes back to drinking he does it deliberately because he wants to lead the old life, and not because he has any desire for strong drink.
>
> Q. How many persons under GOD have you been permitted to cure?—A. Something over 60,000. Of this number, 95 per cent. have been permanently cured, and only 5 per cent. have relapsed.
>
> DR. KEELEY went on to explain, in answer to further questions by DR. TALMAGE, that no analysis had ever been made of his remedy. He said that he defied analysis, and that no chemist on earth could tell what it is. He had been experimenting for thirty years, and could cure the opium or morphine habit just as easily as the drinking habit. He added that it was a mistake to call his cure the bichloride of gold. That name was given to it erroneously because of the gold clubs that had been organized throughout the country. He insisted that bichloride of gold is a chemical impossibility.
>
> "What are your reasons for keeping your cure a secret?"
>
> "It is a system. Drunkenness must be treated systematically. We could not hand it over to the doctors, because they would not handle it properly. I look upon my cure as belonging to the women and children of the country. If I gave out the formula the quacks would destroy it in a very short time. There are only three persons in the world who know the secret, and no one else will ever know it."

We have quoted at some length from this report, and for several reasons. We wish our readers to remember carefully several points contained in it, notably these:

1. KEELEY's early advertising pamphlets and circulars expressly stated that the medicinal agent was bichloride of gold. THE MEDICAL NEWS at once (November 14, 1891) pointed out the fact that a solution of bichloride of gold is a chemical impossibility. Then the later circulars and pamphlets changed the tune to "chloride of gold and sodium." The third change of attitude is indicated in the foregoing, in the remarkable admission that a child could drink a barrel of it without injury. Now, the dullest comprehension can at once see that a medicinal agent capable of producing such profound changes in the human system as the injection is alleged to produce must, in barrel doses, be somewhat injurious to children. Reference to any work on materia medica will hardly authorize the maximum dose of any auric or aurous salt as a barrelful.

In other words, by KEELEY'S express admission, there is no gold in the injection, however much there may be in the business.

This self confessed *reductio ad absurdum* of the whole fraud will be confirmed. Suppose that a "jabber" of one of the institutes, one of the so-called physicians, should have the injecting material analyzed by an expert chemist, in order to set up a rival institute, and suppose that, as a result of that analysis, it should be found that in the injecting material used in the KEELEY institutes there is no chlorine, no chloride or bichloride of anything, nor any gold whatever. This would confirm KEELEY'S remarkable hedging admission, that after having invented a bichloride of gold cure, and then a chloride of gold and sodium cure, there is no gold salt whatever in a barrel of it. The gold is in KEELEY'S pocket, put there by his dupes, and especially by his religious co-partners.

2. Note that the original claims made were that there were no relapses whatever. The "Glory of the Nineteenth Century" now admits 5 per cent. How far this is from the sad truth will be seen by and by.

3. THE GLORY also "defies analysis of his remedy," and says that "no chemist on earth could tell what it is." Will our readers bear this in mind?

4. The statement of reasons by THE GLORY for not giving the remedy to "the doctors" would make an Egyptian mummy laugh. Alas! that the VERY REVEREND DRS. FUNK and TALMAGE are devoid of a trace of humor.

The advertising pamphlet of "The National Bichloride of Gold Institute of Chicago" lies before us, and contains process portraits of the following Reverend Doctors of Divinity as its endorsers and advertisers:

BISHOP SAMUEL FALLOWS, D.D.
REV. F. A. NOBLE, D.D.
REV. J. WOLFENDEN, D.D.
REV. W. T. MELOY, D.D.

Other representatives of modern Christianity, mentioned in the pamphlet as enlisted in the holy cause of KEELEYISM, are G. B. WILCOX, D.D., J. L. WITHROW, D.D., REV. HARRY TAYLOR, D.D., and clergymen galore! MISS WILLARD and the W. C. T. U. are with THE GLORY also.

But, it is not only the genuine original fraud that has the support of the reverend D.D.'s, and the religious folk. These, indeed, seem almost to prefer the fraudulent imitations of the fraud. For example, a correspondent writes us that in *The Voice* of New York of May 5th, there is a "three-column ad." of a certain GARTEN'S "Terchloride of Gold Remedy," endorsed by the leaders of the W. C. T. U., by FUNK and WAGNALLS," etc. etc.

In the thousandfold advertisements of a certain unsafe cure, the most frequently quoted and most enthusiastic commendations come from doctors of divinity, bishops beloved, pastors dear, and pious clergymen. It would almost seem as if "the Church" had gone into the patent-medicine business. In whatever newspaper you please to look the letters of "religious" teachers are paraded, endorsing the most damnable of the quacks' concoctions. It has become proverbial that such advertisers well know both the ease of entrance to the columns—advertising, reading, or editorial—of what is known as the religious newspaper, and also the paying value of such "ads."

Protestants have for centuries amused themselves by sneering at Catholics for the simple faith that believed in the medical miracles wrought by saintly relics, etc., but in all Catholicism there is nothing so rotten, morally and intellectually, as the support given by Protestant clergymen to the robbery and debauchery of their parishioners by the modern quack.

The workings of the demagogic or sham religious conscience it is impossible for the medical psychologist to trace. His own religion is neither gush, nor zealotry, nor humbug. It is modest, real, and genuine. His simple reasoning is likely to be that if these endorsers get pay for their endorsements, they are the most purple-gilled of sinners; if they do not get pay they are the most long-eared of asses, because the proprietors are making huge fortunes by means of these, their most pliant and compliant tools.

The one lesson that stands forth with glaring clearness is that the modest, sensible, and genuinely religious teachers and leaders of the Church would better quit for an hour the splitting of theologic hairs, and turn their attention to their asinine associates, who in striking hands with opera-bouffe medicine and Mephistophelian quackery, turn the stomachs not only of the medical profession, but of what that profession is both prophet and representative—the coming civilization of science and of common-sense.

BEDSIDE INSTRUCTION IN HOSPITALS.

Interest in the question of bedside instruction in hospitals has recently been vividly aroused in Philadelphia by a newspaper report that such instruction was hereafter to be prohibited at the Philadelphia Hospital. Inquiry into the facts shows, however, that this report is not correct. It is probably the intention of the Bureau of Charities and Correction, after due consultation with the Medical Staff of the Philadelphia Hospital, to formulate such wise regulations as may prevent the use of patients for bedside instruction in a legitimate manner by the authorized Staff of the Hospital from degenerating into an abuse of the patients by unauthorized persons.

Quite apart from local considerations, or the regulations that may or may not be enforced at any particular institution, the broad question as to how far the wards of hospitals should be utilized for teaching purposes is one that demands serious consideration. There can be no doubt that the primary purpose of a hospital is to care for the sick; but if, while carrying out this primary object of rendering service to suffering individuals, there can also be fulfilled the supremely important function of affording students of medicine the opportunity to become practically familiar with disease in its varied aspects, and to observe the effect of remedial measures, an additional service will be rendered to mankind at large.

All men are heir to the ills of flesh. All men at some period in their lives seek medical assistance. It is, therefore, to the interest of all men that those to whom they will apply for such assistance shall be qualified in the highest possible degree. Real qualification for the physician's duties is not to be gained in the study, in the laboratory, or in the lecture-room. The man who can pass the most brilliant examination for his degree is not always the best physician. Theory must be married with practice. The instruction gained from books, from experiments, from the living word of the teacher as he explains principles, summarizes medical history, and relates his own rich experience, must be reinforced and made fruitful by actual contact with disease and with patients at the bedside. Either this fructifying contact of theory with practice must be gained under the direction and supervision of experienced teachers, upon whom shall rest the responsibility for the diagnosis of the cases and for measures adopted for the relief of the patients; or it will be gained only at the cost of much perplexity to the practitioner, and more or less suffering and risk to the patient, after the practically unqualified student enters upon the duties of his profession.

One reason why the country doctor — even if less richly cultured from a literary or scientific standpoint than his brother of the city—is often superior to the latter in the readiness with which he meets emergencies, and in the soundness of his judgment under trying circumstances, is that the country practitioner, as a rule, has been bred to practical medicine by constant association in the work of his preceptor.

It has long been a reproach to our American colleges that they would grant degrees to men who had come no nearer to a patient than might be necessary to look upon him from the benches of the clinical amphitheater. In Great Britain and on the Continent of Europe medical teaching has always been largely done in the hospitals, and the tendency to magnify the importance of such teaching and to increase the opportunities therefor that has recently developed in American schools, is from the standpoint of medical education a most desirable step in advance. It is manifestly to the interest of the community to encourage this tendency and to enlarge the facilities at the disposal of the colleges.

But, the question has been asked, is it to the interest of the patients utilized for teaching-purposes that they be handled by scores of inexperienced men, or that their rest be disturbed, in order to exhibit them to students? Is it just to the poor man in a hospital to subject him to intrusions and disturbances from which the rich man is free?

These questions, however, would not be propounded by those who have watched the conscientious hospital teacher on his rounds. To those who have not had the opportunity for such observation it may be said that the attending physician bestows upon the patients entrusted to his care in hospitals the same thoughtful consideration as is extended to those otherwise situated under the most favorable worldly conditions. The very fact that a patient is to be utilized for demonstration ensures an additional amount of care in thoroughness of observation, in accuracy of conclusion, and in application of therapeutic measures, so that the lesson taught may be truly and deeply impressed. The physician would be unworthy of his trust if, by reason of his zeal as a teacher, he interfered with the progress of

his case, or in any way jeoparded its successful issue; and no man should be made a hospital physician unless he can be confidently depended upon to protect the interests of those entrusted to his care.

SOCIETY PROCEEDINGS.

THE MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

Forty-second Annual Session, held at Harrisburg, May 17, 18, 19, and 20, 1892.

FIRST DAY—MAY 17TH.

ADDRESSES of welcome were delivered by Governor R. E. Pattison, Mayor J. A. Fritchey, M.D., and Dr. W. T. Bishop, Chairman of the Committee of Arrangements.

An invitation to send delegates to the Pan-American Medical Congress, to be held in Washington, D. C., in September, 1893, was referred to the Committee on Nominations.

DR. W. D. KEARNS, of Pittsburg, read a paper upon "The Injurious Effects of the Current Methods of Averaging Pupils in the Public School to Determine their Position in their Classes." On motion of Dr. Sibbet, the subject was referred to a committee of three to report at this session. Dr. R. L. Sibbet, Dr. W. S. Foster, and Dr. W. D. Kearns were appointed members of the committee.

DR. THEODORE DILLER, of Pittsburg, read a paper entitled "A Plea for Special State Provision for Epileptics," in which he said that epileptics are a particularly unfortunate class in the community, because of the nature and uncertainty of their disease. They have difficulty in getting employment, and are constant causes of distress to their families, besides being great drains on them. There are 615 epileptics in the State asylums and other State institutions. These patients are unsuitable for these institutions, and are a constant source of hindrance to the other patients. A separate hospital or colony, somewhat similar to that of Bielefeld, in Germany, should be established by the State to provide for indigent epileptics. Here, special hygiene, occupation, and classification could be provided in a way not now possible, in the State asylums. By this plan the epileptics would be better cared for, and the State asylums relieved of a great burden. The full text of the paper is to appear in a subsequent number of THE NEWS.

On motion, Dr. F. H. Edsall, Dr. Curwen, and Dr. Kerlin were appointed a committee to consider the subject of the State Care of Epileptics, and were instructed to report to the Society.

DR. G. R. ROHRER, of Lancaster, read the "Address in Otology." It contained practical hints for daily work. Careful examination is imperatively required in every ear case. A reflector, a head-mirror, and good light are necessary. The speculum should be introduced with care and gentleness. Impacted cerumen is often present. For its removal, the syringe is the best agency. Warm water thrown in the meatus softens the accumulation, and it is readily washed out. A flat probe should be used to press the wax from the walls, when it can be gently removed with the forceps. Eczematous inflammation is very common in the external ear. It should be treated as acute eczema is treated anywhere else. It should be washed but little, and no soap should be used. When the condition becomes chronic, from a two to four per cent. ointment of ammoniated mercury should be employed. When furuncles are present, and the condition is acute, leeches may be applied in front of the ear, followed by the hot douche and black wash. If necessary, an incision should be made, and hydrogen dioxide freely applied. The great point in all ear-troubles is to faithfully keep the part clean when a discharge is present.

DR. EDWARD JACKSON, of Philadelphia, read a paper on "The Mechanical Treatment of Trachoma." He stated that the astringent plan requires a long time and much persistency. The mechanical treatment is preferable, in the form of expression. Knapp's method consists in the employment of a roller forceps. It must be employed with care; the secretions should be thoroughly removed. The rollers should be well centered, should move freely, and not drag, and should not be flattened. The vicinity of the commissures should be thoroughly cleansed. Edema and swelling of the lids follow, but soon disappear; and it is wonderful how quickly a cure will follow. Often no other or after-treatment is required. The application is best made under anesthesia.

DR. J. M. BATTEN, of Pittsburg, read a paper on "Diphtheria." He related the history of two cases of diphtheritic croup successfully treated with calomel. He dwelt on the point that certain forms of diphtheria do best under treatment with the tincture of chloride of iron, potassium chlorate, and whiskey, while other forms do best with calomel or other mercurial. Attention was directed to the importance of local treatment, and the enforcement of a proper prophylaxis was strongly urged.

DR. FREY expressed the belief that diphtheria and membranous croup are not identical.

DR. H. G. MCCORMICK, of Williamsport, stated that he used locally the bichloride spray, and at once gets the disease under control. In seventy-four consecutive cases he had not failed once. He used a solution of 1 : 1500 every hour, for forty-eight hours. As a result, a line of demarcation formed. There appeared to be no need of potassium chlorate and iron. Post-nasal diphtheria is the most difficult of treatment. Dr. McCormick stated that he only used whiskey occasionally as a tonic.

DR. W. B. ULRICH, of Chester, reported that he had given to a moribund child two years old, twenty grains of calomel every two hours until two hundred grains had been taken, with recovery in twenty-seven hours. Diphtheria is a constitutional disease. Dr. Ulrich stated that he had never had bad effects from potassium chlorate, although he had given large doses. He maintained that there is no identity between diphtheria and croup.

DR. PHILLIPS stated that he had utterly failed with mercury.

DR. T. C. DUNN, of West Chester, reported that he had used hydrogen dioxide. He experienced the best effects at once. The agent deodorizes and dissolves the membrane.

DR. BAUER, of Philadelphia, related that he had good success with calomel.

DR. I. C. GABLE, of York, stated that he regarded

diphtheria and croup as one disease. All cases are isolated. He employs alcohol in large doses, practically intoxicating the child, if he can. Locally, equal parts of tincture of iron and glycerin are applied.

Dr. Hiram Corson, of Conshohocken, expressed the view that the two diseases are distinct. Since 1850 he has used ice to the throat and internally. Everything else has failed in his hands. He objected to the employment of whiskey as wrong in every way.

Dr. H. A. Hare, of Philadelphia, endeavored to harmonize the different views by explaining that the various modes of treatment were useful at different stages of the same disease. The difference is one of degree. The disease is both local and constitutional. Hence mercury acts well in the early stage; it eliminates the plastic exudation. After that it is more dangerous than useful, and tincture of chloride of iron and whiskey are best. All cases should be isolated.

Dr. Alexander, of Center County, insisted that diphtheria and croup are two diseases. He stated that he does not isolate cases of croup, and never saw a second case in a family.

Dr. J. Aulde, of Philadelphila, expressed his belief in the identity of the diseases. Local in the incipiency, the local manifestations should be treated early and the multiplication of bacilli prevented. The best agent is hydrogen dioxide, in spray, as a gargle, and internally. Dr. Aulde stated that he used mercury, tincture of iron, and the chlorates. The best of these remedies is mercuric iodide. Calomel acts on the liver and plays the part of an eliminant.

Dr. Dercum, of Philadelphia, stated that he regarded diphtheria and croup as essentially identical. The differences between them depend upon the anatomy of the parts.

Dr. Sibbet, of Carlisle, expressed his belief in the efficacy of the ice-treatment.

Dr. Hull objected that the blood is too commonly saturated with alcohol.

Second Day—May 18th.

Dr. H. C. Wood, of Philadelphia, read a paper entitled "Neuropathic Insanity in Relation to Crime." He made two groups of cases. In one, delusions existed, or a condition of paranoia. In the other, delusions are wanting, or are not evident—a condition of reasoning insanity. Religious belief often runs into religious insanity. Persons so affected are dominated by an idea that they know to be false, but they cannot shake it off. The impulse may be controlled, but it may at any time lead to harm. Others are unable to control it. The reasoning insane are the most to be dreaded. They cannot rely upon their own integrity. Hysteria is not a madness, but it may become such. Dipsomania is a normal human attribute, the basis of many cases of insanity, generally easily controlled at first; but the continuance of the vice alters the nerve-centers. If these cases could be controlled by law, they could be cured. Unfortunately, the law will not allow such control. A nervous criminal cannot be reformed. He has no fear of punishment. Society must protect itself. Cases of this kind, when recognized, should be isolated and made to earn a living. It is proper that all such that are useless and a burden to society should be destroyed, if necessary. They are only a tax on others.

Dr. Hiram Corson expressed himself as in full accord with Dr. Wood.

Dr. Dercum, of Philadelphia, expressed the belief that drunkenness could be cured by legal restraint. The knowledge that repeated crime will bring an enduring punishment would act to restrain drunkards. Such a course would be better than temporary imprisonment, followed by dismissal and an opportunity again to commit crime. There should be a State Inebriate Asylum, in which such patients should be kept, as are other insane patients.

Dr. H. A. Hare read a paper entitled "Some New Medicaments." He had found camphoric acid, given in capsule or in tablets (as it is insoluble in water), twenty grains three times a day, to be of great value in night-sweats of any form. Piperazine had not given as good results in gout or rheumatism as had been expected. It had failed in the cases in which it was employed. The dose is fifteen grains in twenty-four hours. Dr. Hare stated that codeine is not used in diabetes mellitus as it deserved to be. From one to three grains should be administered three times daily, the dose to be increased until it produces drowsiness, when it is to be reduced. He cited cases in which it had been of great value. Croton chloral is an analgesic of special value in facial neuralgia, given in doses of from five to twenty grains three times daily. It generally acts at once.

The strontium salts, bromide, phosphate, lactate, are of value. The bromide acts without causing cutaneous eruptions or gastric irritation, as other bromides so surely do. From ten to thirty grains may be given three times a day. The lactate is of considerable value in albuminuria. It decreases the quantity of albumin in the urine, but this is likely again to increase if the remedy is withdrawn. The dose for this purpose is thirty grains, repeated as seems necessary. It was stated that creasote often fails in pulmonary tuberculosis, and does not act as it was expected from the reports that it would. Two drops are at first given three times a day, the dose being gradually increased until the stomach becomes irritable. Dr. Hare had employed doses as large as from ninety to one hundred drops, but had failed. The remedy is best given in milk. In chronic bronchitis it is of singular advantage, taken until the urine becomes smoky, and then decreased. Given thus, it generally cures.

Dr. H. C. Wood expressed the belief that codeine gives diverse results. Much of its effect, he thought, is due to the contaminating presence of morphine. It fails as often as it succeeds. It is, without doubt, the diet that does the good, and not the drug. Croton chloral is no better than the chloral.

Dr. Hare, in closing, said that in the cases referred to, tincture of opium had failed, but codeine had at once produced good results. Appropriate diet had been tried, but failed.

Dr. X. O. Werder, of Pittsburg, read a "Report of Fifty Laparotomies."

The following officers were unanimously elected:

President.—Dr. H. L. Orth, of Dauphin County.

Vice-Presidents.—Dr. J. B. Roberts, of Philadelphia; Dr. W. B. Ulrich, of Delaware County; J. J. Finerty, of Erie County, and L. S. Gaddis, of Fayette County.

Permanent Secretary.—Dr. W. B. Atkinson, of Philadelphia.

Assistant Secretary.—Dr. J. P. Connelly, of Lycoming County.

Treasurer.—Dr. G. B. Dunmire, of Philadelphia.

For the next place of meeting, Williamsport was selected.

DR. A. A. WOODS, of Erie, read the "Address in Hygiene." He made a plea for better sanitation. After giving certain data, he demanded more extended powers for the State Board of Health and a larger grant of money with which to do the work. The Board had no quarantine powers, though the act creating it required quarantine to prevent the spread of contagion. Pennsylvania is about the lowest on the list of States as to appropriation.

DR. MURDOCH, for Dr. Davis, of Pittsburg, read the "Address in Surgery." He spoke of the many reports of operations, and of the tendency to excess in the performance of certain operations, as laparotomy, gastrotomy, etc. The tide now drifts to operations on the spine and lungs. Antisepsis is used, but coupled with gross carelessness. Ovariotomy is too much resorted to. Suturing of intestinal wounds is a great success. Excision of the esophagus should be preceded by an effort to obtain relief by dilatation by the use of the bougie. Dr. Murdoch alluded to the urgent need of more care in the selling of concentrated lye, as so much injury results from the unintentional taking into the mouth, etc., of the cauterant. The vermiform appendix is useless, and causes much trouble. For the inflammatory affections of the appendix laparotomy is the operation, as it also is for the removal of gall-stones, etc. Supra-pubic lithotomy is more commonly performed than formerly, and is the best operation in suitable cases. Anesthetics are still under discussion. One merits special allusion, *i. e.*, the A. C. E. mixture. The alcohol and the ether modify the action of the chloroform. The mixture is the safest anesthetic.

The discussion was participated in by Dr. John H. Packard, Dr. H. C. Wood, and others.

The paper of DR. W. L. ESTES, on "Some Points in Surgery," was read by title.

DR. M. PRICE, of Philadelphia, read a paper on "Amputation Below the Knee." He took the ground that amputations below the knee should be performed some five inches below the joint, so as to permit of the use of an artificial leg with comfort.

The paper was discussed by Dr. Packard, Dr. Murdoch, and Dr. H. A. Wilson.

The paper by DR. JOSEPH LEIDY, on "Insanity Following Surgery," was read by title.

On motion of DR. S. SOLIS-COHEN, of Philadelphia, it was

Resolved, That the Medical Society of Pennsylvania hereby expresses its highest disapprobation of the practice of giving certificates or testimonials to secret preparations alleged to be of medicinal virtue, and calls the attention of the affiliated county societies to the fact that such action on the part of members of the said societies is in derogation of the dignity of the profession and in violation of the letter and the spirit of the Code of Ethics of the American Medical Association and of this Society.

Resolved, That this Society likewise expresses its disapprobation of the practice of inserting advertisements of secret preparations in the columns of medical journals, such action being an insult to the intelligence of the profession and a degradation of journals indulging therein to the level of the patent-medicine almanac. Especially to be condemned is the action of the *Journal of the American Medical Association* in admitting such advertisements.

Resolved, That copies of these resolutions, duly attested by the Permanent Secretary, be sent to all county societies in affiliation with this Society, to the American Medical Association, to State medical societies in affiliation therewith, and to the publishers and editors of American medical journals.

These resolutions were discussed by a number of members and unanimously adopted.

DR. J. A. LIPPINCOTT, of Pittsburg, presented a report on "Contagious Diseases in Orphan Asylums."

THIRD DAY—MAY 19TH.

DR. J. H. MUSSER, of Philadelphia, read the "Address in Medicine." He said that functional disorders are infrequent as compared with organic. All specialists find cases of organic disease to constitute the greater part of their work. Next in frequency come specific and infectious diseases. Dr. Musser alluded to the usefulness of antisepsis, but maintained that asepsis is even more urgently necessary. If in a given case antisepsis were instituted at once, 90 per cent. of the sequelæ and mortality would be saved. "Colds" need to be treated on the same principles. If a coryza were treated in its incipiency by means of antiseptics, by washing the nasal passases, etc., many additional attacks in the same house would be prevented; for "colds" are contagious and infectious. Chronic infections, such as tuberculosis, imperatively demand antisepsis. Then, rest, less wear and tear, diet and bathing, occupy an important place in treatment. So with renal diseases. In dyspepsia, we may wash out the stomach and regulate the diet, but we must be careful not to overdiet or to overtreat, as with bismuth, etc. General measures are best, and tonics, such as nux vomica, in increasing doses, are especially useful. So with other affections. In fever, the only true antipyretic is cold.

A paper by DR. J. C. WILSON, of Philadelphia, on "The Death-rate of Enteric Fever," was read by title.

A paper by DR. T. J. MAYS, of Philadelphia, on "The Hospital Treatment of Consumption," was also read by title.

DR. E. LAPLACE, of Philadelphia, read a paper entitled "Causes of Failure in the Treatment of Appendicitis." A common cause of failure depends upon tardy treatment. A good deal can be expected from appropriate treatment, such as intestinal drainage, induced by the free use of salines; then, if relief does not follow, the surgeon must act. The indication is to ligate and remove the appendix. Delay here is another cause of failure. Sepsis must be prevented; drainage must be maintained; neglect of these conditions may result in failure. Engorgement is subsequently to be removed by salines.

In the absence of DR. H. G. MCCORMICK, of Williamsport, DR. MONTGOMERY read the "Address in

Obstetrics." It was stated that childbirth and its management are topics important both to physician and patient. Strict antisepsis is imperative. Absorption of microbes is to be prevented, and elimination of noxious matters in the system is to be encouraged. All lacerations should be closed at once, and all débris of placenta, etc., removed with extreme care. Mercuric chloride is best used in a strength of 1 : 4000. It should be employed until the temperature falls. Drainage by means of iodoform gauze should be provided for. Creolin is much less valuable than mercuric chloride. Ergot should be employed to cause closure of the cavity of the uterus. When puerperal infection has begun, all these agencies, with whiskey, are to be energetically employed. The puerpera bears stimulation well. Stimulants should thus be used early and unsparingly. Quinine may be employed as a tonic, not an antithermic. Pilocarpin, hypodermatically, causes lowering of the temperature. The patient must not be starved, but her resources should be husbanded.

DR. TYSON, of Philadelphia, stated that we are often misled by the absence of elevation of temperature, both in peritonitis and in perforation during typhoid fever. Suggestive symptoms are increased frequency of pulse and increased rapidity of breathing.

DR. DUFF, of Pittsburg, expressed faith in asepsis, etc., but he felt that not enough stress is laid on the care of the woman prior to delivery.

DR. ULRICH, of Chester, believed in cleanliness, but not so much in antisepsis. He contended that if we close the uterus we imprison débris. In many thousand cases, without special antisepsis, save cleanliness, he had not had a single death. Labor is healthy ; there is no need of washing out the uterus, unless some special cause has arisen. Too much is done ; there is too much interference with natural labor.

DR. MONTGOMERY said that in regard to labor, cities differ greatly from country places, where perhaps the dangers of septic infection are not so likely.

On motion of DR. A. B. BRUMBAUGH, of Huntingdon, it was unanimously

Resolved, That in view of the great national and even universal importance of the subject of hygiene and public health, the State of Pennsylvania, through its Medical Society, may express its appreciation of, and join in, the petition of the American Medical Association, as presented by its committee of thirty, appointed at its meeting in Washington, D. C., in May, 1891, "to memorialize Congress to create a cabinet officer, to be known as a Medical Secretary of Public Health" ; therefore the Medical Society of the State of Pennsylvania warmly commends the movement, and hereby petitions the Congress of the United States to create a Department of Public Health, the head of which shall be a member of the Cabinet of the President. Believing that the creating of such an officer, of equal rank with the secretaries of other departments of the Government, would greatly stimulate and strengthen the efforts of State Boards of Health in their endeavors to promote and disseminate correct knowledge of sanitation and sanitary subjects, so vital to the well-being of the whole people, all members of the State Medical Society are hereby earnestly urged to use their personal and united influence with their several Congressmen to secure favorable action and the enactment of the law contemplated.

On motion of DR. HAMILTON, of Harrisburg, it was

Resolved, That ten members of the society (no two from one county) be appointed by the president as representatives in the Pan-American Medical Congress, and also the appointment of five members from each county medical society to this Congress be recommended.

On motion of DR. C. W. DULLES, of Philadelphia, it was

Resolved, That the president be authorized to appoint a committee of five, to be known as the Committee on Scientific Business, to coöperate with the Committee of Arrangements and Credentials in securing for the next annual meeting scientific papers and discussions.

DR. P. J. ROEBUCK, of Lititz, offered the following :

Whereas, It is the desire of the Pennsylvania Pharmaceutical Association to offer an amendment repealing Section 11 of the Pharmacy Law, which permits physicians to carry on the retail drug-business without examination ; therefore, be it

Resolved, That it is the sense of the Medical Society of the State of Pennsylvania that no physician should be permitted to carry on the retail drug-business, without proper qualifications, as determined by an examination in practical pharmacy.

Resolved, Further, that it is also the sense of the Society that the Pennsylvania Pharmaceutical Association should use its best efforts in securing action prohibiting druggists, who are not registered physicians, from prescribing for diseases.

After a spirited discussion the resolutions were adopted.

An amendment offered by DR. DULLES and others providing for a scientific committee to aid the Committee of Arrangements was laid over until the next annual session.

DR. H. A. KELLY, of Baltimore, Md., read a paper on "Operation for the Relief of Relaxation of the Vaginal Outlet," illustrated by a series of photographs displayed on a screen. He alluded (1) to the commoner important injuries of the vaginal outlet resulting from parturition ; (2) the clinical characteristics of the complete tear ; (3) simple partial tears ; (4) tears extending up within the vaginal canal, resulting secondarily in relaxation of the vaginal outlet ; (5) the importance of this form of injury ; (6) the treatment of relaxation of the vaginal outlet. Each slide showed a step in the operation.

DR. E. E. MONTGOMERY, of Philadelphia, read a paper entitled "A Consideration of the Relative Advantages of Colotomy and Sacral Resection for the Formation of an Artificial Anus." He reported three cases, one of lumbar colotomy, one of inguinal colotomy, and one of sacral resection. He asserted that the necessity of performing lumbar colotomy is no longer apparent, for the reason that later methods of abdominal surgery had rendered the increase of danger from opening the peritoneal cavity so slight that the mortality was no longer to the advantage of the lumbar operation.

Certainly the difficulty of caring for the discharges was much greater than when the operation was done anteriorly. There is a certain class of cases in which

colotomy is the only plan of procedure to which we can resort, as the disease is situated so high up that the gut cannot be reached through the pelvis. In all cases in which the disease, however, is confined to the rectum, sacral resection presents the best method of procedure, for by it we are not only enabled to establish an artificial anus, but are afforded the best method of procedure in the removal of diseased tissue. An anus situated in this region offers the advantages of being better under control in the wearing of a pad to prevent clothing and person from being soiled; secondly, the patient is not required to assume an unnatural attitude in order to accomplish the evacuation.

DR. J. M. BALDY, of Philadelphia, read a paper on "Chronic Endometritis." He has found the condition to be common. The causes are septic and specific infection. Gonorrhea is largely its cause. The acute form soon becomes chronic. The best treatment comprises cervical dilatation under ether, thorough curetting, washing out, applying tincture of iodine and packing with iodoform gauze. After a week, ergot is given if there be hemorrhage, or if the uterus is relaxed, say half a dram of the fluid extract three or four times a day; and iodine is applied locally twice a week.

DR. F. LEMOYNE read a paper entitled "Suggestions for Operation in Laceration of the Perineum in Labor." He detailed a case of primary operation for laceration illustrating the advantage of thorough drainage of the vagina, and offered some suggestions for the satisfactory accomplishment of that indication.

DR. I. N. KERLIN, of Elwyn, offered the following, which was unanimously adopted:

Whereas, The State of Pennsylvania in common with the most advanced States of the Union, has for more than thirty years made special provision for the training and protection of idiotic and feeble-minded children; and

Whereas, This provision has been very limited, extending to not more than one-tenth of those whose infirmities need it; therefore

Resolved, That the Legislature of Pennsylvania be petitioned by this body, the Pennsylvania State Medical Society, assembled at Harrisburg, May 19, 1892, to establish a second institution for idiotic and feeble-minded persons, in the western part of our State, to meet the necessities of our western population, so that the overburdened Pennsylvania Training School for Feeble-minded Children at Elwyn be so relieved that it may minister to the great demands made upon it from the eastern tier of counties.

Resolved, That the secretaries of the county medical societies of Western Pennsylvania are hereby constituted a committee to carry out the intent of these resolutions.

It was agreed that a memorial page to the late Dr. D. Hayes Agnew should be placed in the next volume.

The paper of DR. C. P. NOBLE, of Philadelphia, on "Anterior Displacement of the Uterus," was read by title.

The Society adjourned, to meet on May 18, 1893, at Williamsport.

Adolph Jarisch has been made Professor-extraordinary of Dermatology and Syphilis at Gratz.

ASSOCIATION OF AMERICAN PHYSICIANS.

Seventh Annual Meeting, held at Washington, May 24, 25, 26, 1892.

FIRST DAY—MAY 24.

DR. HENRY M. LYMAN, of Chicago, delivered the "President's Address." He paid glowing tribute to the memory of Dr. Francis Donaldson and Dr. Henry Ingersoll Bowditch, members of the Association who had died since the previous meeting.

The past year has not been particularly fruitful in brilliant discoveries within the field of medicine. Medical progress can advance only as the allied sciences pave the way by discoveries that can be utilized for the explanation of physiologic and pathologic phenomena, thus rendering possible new investigations in therapeutics. For these reasons, it is highly important to carefully follow the course of research in all departments of scientific investigation. Great activity has characterized the workers in those departments; during the past year a number of beliefs that were previously held upon hypothetic grounds, have been subjected to the final test of experimental evidence, thus enlarging the field in which the uniform operation of the laws of physics and chemistry has been demonstrated. A good deal has recently been accomplished in the realm of astronomy by the aid of photography and the spectroscope. To physicians, the principal interest lies in the demonstration thus afforded of the unity of type and method in all the cosmic movements of matter, enabling us to read in the language of the stars the past history and the future course not only of our own solar system, but of the planet upon which we dwell.

The experiments in electricity that were announced three years ago by Professor Hertz, of Karlsruhe, have continued to bear fruit during the past year. It may now be assumed as experimentally demonstrated that electricity, as well as light and heat, is what it has long been supposed to be—a mode of motion in an all-pervasive ether. By this demonstration we are brought one step nearer toward the complete definition of the antithesis between mind and matter.

Among the biologists, during the past year, research has been particularly occupied with the investigation of the elementary composition and attributes of protoplasm. In connection with the questions that bear upon the subject of heredity, many interesting observations have been published; the investigations of Strasburger, Flemming, Guignard, and Fol have thrown new light upon the phenomena of fecundation and reproduction, giving reason to hope that in no very distant future, the problems of heredity may receive a satisfactory solution. Another important question regarding the ultimate organization of protoplasm itself is gradually approaching its solution. Two rival hypotheses at present occupy the field. Altman, Straus and Vogt are of the opinion that cell-protoplasm is to be considered as an aggregation of coördinated elementary organisms that bear to the animal or vegetable cell a relation not unlike that of independent microbes. The constituent cells of the tissues, according to this hypothesis, are supposed to be made up of aggregations of a microzoic or microphytic nature, which differ from ordinary bacteria and protozoa

only by their smaller dimensions and their capacity for coördinate activity. The bearing of such speculations upon the facts of infection and of fecundation is quite obvious. On the other hand, Bütschli maintains that it is entirely unnecessary to assume the existence of any special coördinating force, and is of the opinion that all the phenomena that are exhibited by protoplasm may be produced by the operation of ordinary chemic and physical forces.

The past year has been distinguished by the completion of the new edition of Eichhorst's great work on *Internal Medicine*, and by the appearance of the first two volumes of the French *Traité de Médecine*. In the United States, Osler, a member of our Association, has laid upon the medical profession a debt of gratitude for his admirable volume on the *Practice of Medicine*. The profession is to be congratulated upon these epoch-making achievements, especially since they indicate the complete recuperation of the French school of medicine from the stunning shock of the Franco-Prussian war. The consecutive volumes of Eichhorst remind one of the invincible German infantry—ponderous, thoroughly trained and invincible, but war-worn and weather-stained to the last degree. Turning from these serried ranks to the French side of the line, we find all the pomp and circumstance of war, all the glitter of gold, the splendor of apparel, the *élan* and *esprit* that have always characterized the French nation. Judging from the already published volumes, the new *Traité de Médecine* will be, when completed, the most valuable contribution to the literature of internal medicine that has been yet produced. The world certainly cannot yet dispense with the services of the French any more than it can do without the Germans.

The paper of Dr. Pepper, of Philadelphia, entitled "Report of a Case of Glanders, with Results of Bacteriological Study," was read by title. The case was that of a white man, aged fifty-five years, a shoemaker who had been healthy until eighteen days before entrance into the hospital. He was a moderate drinker. His illness began with the appearance of two indurated nodules under the skin, painful at first, but later only tender on pressure. At the same time there were malaise, diarrhea, excessive frequency of micturition and slight fever. On entrance into the hospital, eighteen days later, similar subcutaneous nodules were found in several localities; the patient was weak and stupid; the pulse was rapid and the respiration hurried. The skin over the nodules was in some places healthy, in others dark red, and subsequently ulcerated. The patient's condition grew worse and worse with the appearance of new nodules, and after a period of complete stupor with subsultus tendinum and other nervous manifestations, he died. Careful examination of the blood was made repeatedly during life, for the purpose of determining the presence of bacteria, but none were found. The blood contained 4,800,000 red corpuscles to the cubic millimeter, all of normal appearance at the first examination, and there was mild leukocytosis. On post-mortem examination numerous bullous vesicles were found on the anterior surface of the face, trunk, and extremities, with a few patches of more extensive excavation and necrosis. The lungs contained numerous areas of lobular pneumonia, some of which had become cheesy in the center. Similar nodes were seen in the larynx, in the liver, and in the muscles of the extremities; and in the latter two situations there were also small abscess-cavities, formed by the breaking down of the nodules. Microscopically, the nodules showed the histology of glanders, and in some instances, notably in the skin and pulmonary lesions, glanders-bacilli were found in moderate numbers.

Typical cultures of glanders-bacilli were obtained from the pus of subcutaneous nodules, and guinea-pigs were successfully inoculated. By accidental abrasion and inoculation the hand of the experimenter became infected, and the nodule that developed and was subsequently removed showed a structure similar to that of those of the original patient and the guinea-pigs.

There is no evidence to show the mode of infection of the patient, since his occupation and life had not brought him into association with horses. He worked with leather, but only such as had been thoroughly tanned.

Dr. Wilkins, of Montreal, read a paper on "The Cold Water Treatment of Typhoid Fever," which is published in the current number of The Medical News.

In the discussion Dr. Osler, of Baltimore, gave the statistics of the treatment of typhoid fever at Johns Hopkins Hospital. Under symptomatic treatment the mortality was high, while under the Brand treatment the mortality was about 7 per cent.

Dr. Pepper, of Philadelphia, gave credit to Dr. J. C. Wilson for his early advocacy of the cold-bath treatment. He advised the use of the portable tub in private practice, and expressed his conviction of the great value of the method generally in a vast majority of cases. It should be begun in the early stages of the disease. A highly important part of the treatment is the friction during the bath.

Dr. Atkinson alluded to the large number of cases in which the temperature never reached 102° or 103°. He asked concerning the use of the cold bath in these cases.

Dr. Tyson, of Philadelphia, doubted the great value of the friction.

Dr. Stockton, of Buffalo, thought that patients with temperatures under 102° or 103° were often benefited by the bath, and that, therefore, the good effects of the bath are not limited solely to a lowering of the temperature.

In reply, Dr. Wilkins agreed that friction was advantageous, and thought its omission constituted an objection to the pack alone. High temperature has a paralytic effect on the vasomotor system, and hence the value of friction to keep up the elasticity of the capillaries. He did not think the bath was contra-indicated by the fact of menstruation. He also saw no objection to the bath if the temperature should be low.

Dr. Victor C. Vaughan, of Ann Arbor, presented an interesting paper entitled "A Bacteriological Study of Drinking-water," reporting the results obtained by chemic and bacteriologic examination of one hundred and forty-eight samples of drinking-water that had been sent to the Hygienic Laboratory of Michigan University by health-officers. From these, thirty-one kinds of bacteria have been isolated and studied sufficiently to admit of identification. Of these thirty-one species, twenty-four fail to grow at a temperature of 38° C., and consequently

cannot cause disease. Of the seven remaining species, three are without effect upon rats, guinea-pigs, rabbits, and mice, while four are toxicogenic to these animals. The toxicogenic species differ morphologically from one another and from the bacillus described by Eberth as the cause of typhoid fever, but all produce practically the same effects upon animals, the difference being in degree rather than in kind. Of the five (the four toxigenic germs and that of Eberth), the bacillus venenosus is the most virulent. It was first found in the water of a well on the premises of a milkman whose patrons were prostrated with typhoid fever. It was also found in the milk. This germ is much shorter and thicker than that of Eberth as obtained from the Hygienic Institute of Berlin. As taken from the water, it forms a heavy, yellowish-white growth on potato, but when taken from the spleen of a guinea-pig that has survived inoculation for some days, it forms an almost invisible growth.

Each of the thirty-one germs was described in detail, and the results of a large number of inoculation-experiments with the toxicogenic germs were given.

The full text of the paper is to appear in the *American Journal of the Medical Sciences.*

In the discussion DR. STERNBERG spoke of the difficulty of differentiating the distinctive characteristics of the bacillus of typhoid fever, because the organism varies so greatly according to the media and methods of cultivation.

DR. WELCH alluded to a lack of clearness in Dr. Vaughan's distinction between what he called toxicogenic and pathogenic bacteria, and also emphasized the difficulty of determining the distinctions between the different varieties of typhoid bacilli, according to their sources, etc. The secondary lesion, due to the invasion of the bacillus coli communis, he also thought had often been mistaken for the work of the typhoid bacillus, the lesions thus often misinterpreted resulting in a serious confounding of the two germs and their effects.

In reply, DR. VAUGHAN alluded to the decided advantage it would have been to his own study if he could have had the spleens (as well as the samples of drinking-water) of the persons dying of typhoid fever.

As to the words toxicogenic and pathogenic, he wished, in differentiating their uses, to keep the latter word for a definite meaning, leaving the former large and vague in significance. Dr. Vaughan contended that typhoid fever may originate without traceable preëxisting infection from previous cases, and that different germs or varieties of one family may set up the disease. He does not believe in an origin *de novo;* the disease is always due to microorganismal agency, but a number of different and widely-existing germs may cause it. Tolerance to these germs is easily secured in animals, and, just so, man may acquire a tolerance for one germ and tolerance for one variety; thus, the bacillus of Eberth insures a tolerance for others of a similar pathogenic action.

DR. THOMAS S. LATIMER, of Baltimore, read a paper entitled "A Brief Summary of the Clinical History and Treatment of Two Thousand and Twelve Cases of Alcoholism, of which Eighty-seven were Maniacal." He contended that the clinical phenomena attending excesses in the use of alcohol are the direct result of overstimulation, and are not due to the abrupt withdrawal of the stimulus. Though the ability to swallow and to retain stimulants is frequently wanting, the desire for them almost uniformly persists. Alcohol in any form or quantity is unnecessary in the treatment of such cases, and is usually hurtful. The absolute and immediate withdrawal of alcohol is of the first importance in the treatment of all the symptoms due to its excessive use, even in cases characterized by great feebleness and inability to partake of food. Forced feeding is rarely necessary, and is of doubtful utility in most cases. For the protection of the patient no kind of bonds is called for, and when necessary for the protection of others, or for the contents of the room, they injuriously affect the mental state of the patient.

The full text of the paper is to appear in a subsequent number of THE MEDICAL NEWS.

DR. GEORGE M. STERNBERG, Lieut.-Col. and Surgeon U.S.A., read a paper entitled "Practical Results of Bacteriological Researches." He contended that science does not demand practical results, but investigates for the purpose of establishing facts and explaining phenomena. Medicine, however, is eminently practical in its aims, and practising physicians, as well as intelligent laymen, meet every announcement of a new discovery in pathology with the question, "Does it aid in the cure of disease?"

Heretofore, the bacteriologist has been compelled to admit that the discovery of the specific cause in a considerable number of infectious diseases has not resulted in the discovery of a specific treatment for these diseases.

Recently, however, experimental evidence has been obtained that leads to the belief that, in a number of infectious diseases, at least, the toxic bacterial products, which give rise to the morbid phenomena characterizing these diseases, may be neutralized in the infected individuals by the administration of anti-toxines obtained from the blood of immune animals.

The practical results of bacteriologic researches in the field of preventive medicine were also briefly referred to.

The establishment of aseptic surgery on a scientific basis also depends on bacteriologic researches relating to the pyogenic micrococci commonly concerned in wound-infection. The treatment of localized infectious processes, when these are accessible to local treatment, has been favorably influenced by the exact knowledge relating to antiseptic and germicidal agents obtained by the researches of bacteriologists.

Reference was made to the recent experimental evidence relating to anti-toxines in the blood of animals that have acquired immunity to virulent cultures of the bacillus of tetanus, the micrococcus of croupous pneumonia, the bacillus of diphtheria, the bacillus of tuberculosis, and to the virus of rabies; also to the recent experiments of Ehrlich showing that animals may acquire immunity to the pathogenic action of certain vegetable toxalbumins—*ricin* from the castor oil bean, and *abrin* from the jequirity bean.

Finally, an account was given of experiments recently made by Dr. Sternberg, in Brooklyn, which show that the blood of a calf that has been vaccinated, and consequently is immune to vaccinia, contains a substance that neutralizes the specific virulence of vaccine lymph, either bovine or humanized.

Dr. Sternberg closed his paper by stating that it is his intention to follow up this line of investigation, and to endeavor to isolate the anti-toxine of vaccinia; also to test the question of its possible specific action in neutralizing the smallpox virus in infected individuals before or after the development of the disease.

The paper will be published in full in the July number of *The American Journal of the Medical Sciences.*

In the ensuing discussion DR. WELCH spoke of Kitasato's conclusions as to immunization, the law seeming to be that the more originally susceptible the animal is to the disease the greater is the power of immunization conferred by the blood of the immune animal. He also had doubts as to the striking results said to have been secured by certain investigators in securing immunization of man by means of the serum of the blood of animals.

DR. VAUGHAN also advised conservatism in drawing conclusions as to immunity in animals. It is easy to render animals immune, but the immunity is *temporary* and lasts but a few months, as in Dr. Sewall's experiments in pigeons and rattlesnake poison. Dr. Vaughan thinks the agent must be of the nature of a ferment. It is not necessary that the substance shall be *per se* poisonous.

DR. LYMAN also emphasized the fact of the transient character of the protection conferred by immunization-experiments.

In the absence of DR. E. L. TRUDEAU, of Saranac Lake, his paper entitled "The Treatment of Experimental Tuberculosis by Koch's Tuberculin, Hunter's Modifications and other Products of the Tubercle-bacillus," was read by DR. W. H. WELCH, of Baltimore. The objects of the research were to determine: (1) whether or not Koch's tuberculin has any curative influence in inoculated guinea-pigs; (2) the curative value and dangers of Hunter's modifications of tuberculin in experimental tuberculosis; (3) whether the remedial element of liquid cultures of the tubercle-bacillus resides in the bacterio-proteïn of which the bacilli are composed or in the soluble albumoses and toxines produced in artificial culture-media, as the result of their life-history.

The first part of the paper was devoted to a consideration of the effects of Koch's tuberculin and of Hunter's modifications, the conclusions reached being: (1) that Koch's tuberculin does not cure experimental tuberculosis in the guinea-pig, although its specific influence on the primary lesions is indisputable; (2) Hunter's modification, C B, contains less of the remedial principle than does tuberculin, and is quite as dangerous; (3) modification B is as efficacious as tuberculin, and is free from some of its dangers.

In the second part of the paper were described experiments made to determine whether the curative substance in liquid cultures of the tubercle-bacillus resides in the bacilli (bacterio-proteïn) or in the beef-broth in which they have grown.

The most instructive evidence was obtained by treating rabbits inoculated in the anterior chamber of the eye.

The following conclusions were based on these studies: (1) solutions of bacterio-proteïn have a doubtful and at best a feeble remedial influence on experimental tuberculosis; (2) they produce suppuration and serious constitutional impairment, which may occasionally result in organic disease and death; (3) the liquid culture-medium in which tubercle-bacilli have developed, but from which they have been removed by filtration, contains the elements that bring about reaction and cure in tuberculous tissue; (4) experimental tuberculosis in the rabbit's eye can be cured by injections of this filtrate of liquid culture; (5) the permanency of the cure has not yet been determined.

Photographs and living animals illustrating the effects of the treatment and the entire restoration of the inoculated eyes under treatment with the liquid of filtered cultures were shown.

DR. KINNICUTT spoke eulogistically of the great value of Dr. Trudeau's work, and made the interesting statement that by mutual agreement, but without any knowledge of the results of each other, while Dr. Trudeau had been experimentally working with Koch's tuberculin and Hunter's modification, he himself had been proceeding clinically on the same lines. Not until today had he known of Dr. Trudeau's conclusions. His own clinical results went to show that tuberculin *does* contain a remedial principle. Trudeau's second conclusion has been proved absolutely true by his experience at St. Luke's Hospital. The third proposition also conforms with his own clinical experience. In two of seven well-marked cases of pulmonary tuberculosis no difference in physical signs followed the treatment; in the third case the improvement was "most marked;" in the fourth it was distinct, but less marked; in the fifth, decided; in the sixth, most marked; in the seventh, there was a positive arrest of the disease. The speaker also said that Dr. Trudeau had proved that creasote, even given in enormous doses, had no effect in checking the disease in guinea-pigs.

DR. J. P. CROZER GRIFFITH, of Philadelphia, read a paper entitled "Mid-systolic and Late-systolic Mitral Murmurs." He considered those murmurs that, though having the area of diffusion and the usual general symptoms of mitral regurgitant murmurs, yet do not occur until the middle or latter part of the systolic period. Three cases were reported. The first presented the symptoms of mitral regurgitation. The apex-beat was unattended with a murmur; then, after a pause, came a distinct musical murmur; and then, after another pause, the second sound. The case was thus a typical example of *mid-systolic* murmur.

The second case exhibited a murmur just before the second sound. Its area of diffusion was entirely that of a mitral regurgitant murmur. It was so close to the second sound, and at times so short, that its true nature was at first not certain. This case was therefore a typical instance of the *late-systolic* murmur.

The third case resembled the second in some respects. As in the second case, the murmur ran up to, but did not replace the second sound. Unlike the murmur in the second case, however, the murmur in the third case began earlier in the systolic period. It thus represents a combinaation of the mid-systolic and late-sytolic murmurs.

Murmurs of this sort are rare. But little reference is made to them in medical literature, and generally they are wrongly called "post-systolic." This term would

only be applicable on the theory that the systole lasted only to the beginning of the "short silence," and that the silence was cotemporaneous with relaxation of the ventricle.

It has been maintained by several investigators, who have drawn their conclusions from cardiographic studies, that the closure of the aortic valve does, indeed, occur, not at the beginning of the diastole, but at a slightly later period. This view, however, presupposes the existence of a physiologic aortic regurgitation. The recent studies of Martius, together with the older experiments of Ceradini, show that no such regurgitation takes place. The blood continues to stream from the ventricle until a very short period of time before the second sound is heard. During this period the ventricle maintains its contracted state, a backward whirl of blood in the aorta brings the leaflets in apposition, and then the actual recoil, taking place with the beginning of the diastole, simply puts the closed leaflets on the stretch and produces the second sound. This theory, so well sustained by the studies of the investigators named, renders it impossible that a murmur heard just before the second sound occurs could be due to friction of blood on the roughened aorta during its recoil upon the aortic valve—this being the opinion advanced by Skoda and others after him. Such a murmur is physiologically impossible.

The last two cases reported bear out this view from a clinical standpoint. The murmurs lasted quite up to the second sound, yet the cases were clearly instances of mitral regurgitation. The fact that the murmurs did continue so closely up to the second sound is also a proof that the "persistence time" of Martius, during which the ventricle simply remains contracted, must be of exceedingly short duration, as, indeed, this author admits. The very brief interval between the two parts of a double aortic murmur is also evidence of the briefness of this period.

The murmurs in all three cases varied considerably at different times. It would seem, then, very probable that regurgitation was taking place during nearly the whole of the systolic period, but that for some reason it only became evident as a murmur at certain portions of the period. In this respect the murmur is exactly analogous to the potential pre-systolic mitral murmur described by Bristowe.

The full text of the paper is to be published in the *American Journal of the Medical Sciences*.

SECOND DAY—MAY 25TH.

DR. W. T. COUNCILMAN, of Baltimore, opened the discussion upon "Dysentery." He considered the Etiology and Pathology, presenting the results of a study of thirty-four cases. He divided dysentery into three forms: (1) diphtheritic, (2) catarrhal, and (3) amebic. Diphtheritic dysentery is characterized by necrosis of the intestinal epithelium and a fibrinous exudation. It is the form usually encountered in acute epidemics. It may also appear in the course of a number of diseases, and may be produced by a number of causes. There is nothing in the anatomic lesions by which the action of a definite pathogenetic agent may be distinguished.

Catarrhal dysentery is characterized by an inflammation of the mucous surface of the intestine, leading to the production of shallow ulcers. Affections of the lymph-follicles are more common in catarrhal than in the other forms of dysentery. The statements made in connection with diphtheritic dysentery also apply to catarrhal dysentery. In both forms, abscess of the liver may appear, but is very rare.

Amebic dysentery is characterized by definite lesions in the large intestine and elsewhere. Eight of the thirty-four cases were instances of this kind. Four types of ulcers were described. The lesions always have the same character, and in them can be recognized the action of a common agent. There are extensive ulcerations of the intestines, which, in contradistinction to those of the other two forms, appear to be produced, not by extension downward, from the surface, but by a primary infiltration of the submucosa, with subsequent destruction of the overlying mucous membrane. The number of amebæ found is directly proportionate to the activity of the process. Clinically, the disease is characterized by remissions and great chronicity.

Abscess of the liver and lung is more frequent in amebic dysentery than in the other forms.

The disease is caused by the ameba dysenteriæ.

It forms the most of the cases of tropical dysentery.

DR. A. BRAYTON BALL, of New York, considered the "Symptoms, Complications, and Treatment of Dysentery." He first took up the differential symptomatology of (1) catarrhal colitis, (2) diphtheritic colitis, (3) amebic colitis, (4) secondary colitis. The most-marked characteristic of amebic dysentery is the absence of uniformity of the symptoms. The duration of the disease is longer than is that of the other forms of dysentery, chronicity being a marked feature. Dysenteric paralyses have been observed. Paraplegia is the most common. The palsies usually develop rapidly, but function is soon restored. Exceptionally, the palsy is more protracted. In some cases, no doubt, other causes than the dysentery have been operative, such as multiple neuritis, for instance. Dysentery seems to predispose to the development of anemia. A malarial complication is common. The febrile symptoms then usually display intermittency. The arthropathies sometimes observed in connection with dysentery may be considered as allied to other arthropathies of septic origin.

The treatment of dysentery is yet and must remain symptomatic. Ipecac has been extensively employed in India, and has reduced the mortality from 50 per cent. to 15 per cent. The drug must be given in heroic doses. The treatment has not been largely adopted in the United States, where smaller doses are usually employed. The administration of large doses of opium is illogical and inadvisable. The cure of dysentery does not consist in a suppression of the symptoms. Calomel is no longer recommended. The reaction against calomel, however, has, perhaps, gone too far. Corrosive sublimate may be given in small doses. Treatment by the rectum is growing in favor. Suppositories of ice, or of cocaine, or containing astringents have proved beneficial. The methods of rectal irrigation were described. In one case, Dr. Ball successfully employed large injections of quinine in conjunction with bismuth subnitrate. The possibility of damage to, or rupture of, the colon should lead to caution. A full meat diet is to be recommended. The nutrition must be sustained.

DR. W. W. JOHNSTON, of Washington, discussed "The

Treatment of Acute Dysentery by Antiseptic Colon and Rectal Irrigation." He first took up the method of irrigation with cold and warm water, giving Kent, of Bladensburg, credit for being the first to employ ice-water in this way in dysentery. Subsequently, O'Brien stated that in dysentery "the chief curative indication should be to pass up the gum-elastic tube and introduce it into the sigmoid flexure, in order to give exit to the accumulated and pent-up contents of the cecum and colon." Antiseptic irrigation has been recommended for more than a century. Among the agents thus used are Peruvian bark, chamomile flowers, calumba, charcoal, calcium chloride, sodium hyposulphite, creasote, carbolic acid, sodium salicylate, sodium borate. Two causes have coöperated to draw renewed attention to rectal and colon antisepsis: one is the growing belief in the specific and contagious nature, with the recent discovery of the ameba, of dysentery; the other is the dissatisfaction with other methods and the effort to find in this disease a direct, rational and successful treatment. The strong arguments for the superior advantages of antiseptic irrigation are found in the complete and successful manner in which it meets the peculiar pathologic conditions of dysentery.

Dysentery presents one noteworthy feature—the rectum and colon form a distensible cavity, closed below by the sphincter. This cavity, especially its sacculated and most-dilated lower portion, becomes distended with the products of the inflammatory process and of digestion, the whole being the seat of multiplying bacteria and undergoing disintegration. The sphincter becomes irritable, relaxes frequently but irregularly and spasmodically, and contracts abruptly and violently, closing the orifice before the rectum is completely emptied. Thus the rectum becomes like an acutely inflamed bladder. A portion of its contents is expelled; a residuum is always left — sometimes small, sometimes large, but always in a state of active decomposition. The first indication, then, is to empty the rectum; the second, to wash out the cavity and keep it empty and clean. The routine treatment of dysentery tends to aggravate the retention of noxious material; opium-suppositories paralyze the expulsive muscles, but do not relax the sphincter; the number of movements is lessened and they are smaller, but the dangers are increased in proportion to the apparent success of the treatment, and the more severe the case and the more energetic the treatment, the greater is the danger. In the earlier methods of rectal and colon treatment, water was thrown into the bowel, retained for a certain time, and then expelled. The procedure is objectionable when the disease is acute, and is better adapted to subacute or chronic cases. The process is not strictly one of irrigation. The only procedure worthy of this designation is that in which there is *free* and *immediate* escape of the fluid thrown in. To wash out the rectum a double, in-and-out, hard-rubber tube, passed into the bowel for from five or six to eight inches, may be employed. Through this is passed a current of water from a fountain-syringe. Two soft-rubber tubes, passed side by side, the larger for the escape-current, are better and more comfortable. The colon cannot be distended with water or be irrigated with the same facility as can the rectum. Water can be made to pass through the sigmoid flexure, but the passage of a tube is difficult. A partially flexible tube should never be used; nor does a small tube pass as readily as one that more nearly fills the bowel. Distending the rectum with water as the tube advances does not favor the passage as much as leaving the bowel empty. The tube finds its way better along the mucus-covered intestinal wall. On account of the difficulties to be overcome, irrigation of the colon must be practised with one tube. A half-pint or a pint of fluid is forced into the colon, and is at once permitted to escape.

Rectal irrigation is indicated in cases of catarrhal dysentery, the stools being small and containing blood and mucus; and in all cases in which the general and local symptoms are relieved by the treatment. If fever, delirium, restlessness, or symptoms of general infection continue, or if the stools are large, thin, with a gangrenous odor, containing blood, mucus, and shreds of tissue, then an attempt should be made to pass the tube into the sigmoid flexure for higher injection. The danger of perforating an ulcer should alway be borne in mind. The quantity of water employed varies; as a rule, the water should pass in and out until it returns perfectly clear. Provision must be made for the escape of all of the fluid injected. The frequency of irrigation depends upon the number of stools, the state of decomposition in the bowel, and other conditions. A good rule is to try to prevent the patient from having any stools at all. The bowel should be emptied only through the introduced tube; at first once in three hours, later three times a day. The rule is to keep the rectum clean. The irrigating fluid may consist of water only, hot or cold, or a non-irritating antiseptic may be added. Mercuric chloride, in solutions of 1 : 5000, has been successfully employed. Tannic acid, salicylic acid, thymol, aseptol, creolin, zinc sulpho-carbolate, alum, hydrochloric acid, carbolic acid, boric acid, the sulphites, and hyposulphites have all been employed.

Dr. W. C. Dabney, of Charlottesville, Va., presented "A Contribution to the Study of Hepatic Abscess," based upon 108 cases collected from various sources. He indicated that suppuration may be induced in the liver by bacteria or their products brought by the bloodvessels. Infection through the hepatic artery and vein are extremely rare; the portal system of vessels is the most common channel of infection, especially in connection with ulcerative disease of some associated organ. In a considerable proportion of cases, however, there is no history of previous disease of the intestine or of any organ connected with the portal system. The individual diseases and injuries of the organs connected with the portal system to which hepatic abscess has been attributed are: dysentery; appendicitis; gastric and duodenal ulceration; operations on, or diseases of, the rectum; typhoid fever; suppuration of the umbilical vein in infants; ulceration of the cervix uteri; peri-uterine inflammation; suppurating ovarian cysts; lithotomy operations. Tuberculous ulceration of the intestinal seems not to lead to abscess of the liver. The ulceration of typhoid fever is a rare source of such abscess. Ulceration of the bowel, which often causes dysenteric symptoms, and is spoken of as dysentery, has been considered the most common cause of hepatic abscess, but it has been observed that the dysentery associated with abscess was unlike the common form and

was often mild in character. It appears that the development of abscess of the liver is not due to the character of the intestinal ulceration, but to that of the substances formed in the ulcer and carried thence to the liver. Abscess of the liver may develop as early as two weeks after the commencement of an attack of dysentery, but the usual interval is from four to twelve weeks. It is almost impossible to state how long a time must elapse after apparent recovery from dysentery before the patient can be considered free from the danger of hepatic abscess. Ulceration may long persist in the absence of symptoms. Hepatic abscess may remain latent for an indefinite time. Dysentery may recur one or several times in the same person, at intervals of several months or even years.

The entrance of pyogenic substances into the liver by the lymphatics is of questionable occurrence. It is possible for the suppuration in the liver to extend to the adjacent pleura and lung through the lymphatic vessels of the liver. Suppuration may occur around the bile-ducts and lead to abscess-formation from : (1) retention of bile, (2) the presence of gall-stones, (3) the entrance of intestinal worms into the ducts, (4) probably, also, from a cholangitis of unknown origin. The extension of suppurative inflammation from adjacent parts or organs may occasionally induce hepatic abscess. Injuries to the liver lead to hepatic abscess in a large number of cases. These injuries may be penetrating wounds, simple contusions without external injury, or they may be causes of fracture of the ribs, and lead to hepatic abscess, and possibly cause hepatic abscess secondarily.

Certain general local conditions are favorable to the development of hepatic abscess. A hot climate is usually considered a potent factor. Heat alone, however, is probably not the active agent; most likely it furnishes one of the conditions requisite for the growth and development of amebæ, so that it is probable that the abscesses that are greatly influenced by climatic conditions are amebic in character. Chilling of the overheated body is thought to be a cause, and it is claimed that horseback riding is likely to induce hepatic abscess. The weight of evidence seems to be clearly against the influence of malaria as a cause of abscess. It is possible that the real connection between malaria and hepatic abscess resides in the fact that the same conditions are favorable for the development of the plasmodium malariæ and the ameba of dysentery. Malaria may possibly weaken the resisting-power of the liver, and thus act as a cause. Intemperance is universally recognized as a predisposing cause of hepatic abscess in India, and it is probable that it is so elsewhere. In India even moderate drinkers are liable to hepatic abscess. Adult males are far more liable to abscess than are children and women. Young people, however, are by no means exempt.

Abscesses are usually situated in the right lobe of the liver. Even when there are multiple abscesses the right lobe is chiefly involved. It would, furthermore, seem that the upper part of the right lobe is involved rather more frequently than is the lower part.

The number of abscesses is variable. In cases of pyemic origin the abscesses are, in most cases, multiple and small. In cases dependent upon other causes, the abscesses are usually few. In thirty-one cases of dysentery or diarrhea, or in which ulceration of the large bowel was found at the autopsy, there were multiple abscesses in fifteen cases. In fourteen cases there was but one abscess. When multiple abscesses exist, the longer the case lasts the greater is the probability that the adjacent abscesses will communicate with one another. This, however, does not justify delay in surgical treatment, because the longer the duration the greater, as a rule, is the destruction of hepatic tissue, and the greater is the danger from exhaustion or from rupture of the abscess in some unfavorable direction.

The contents of hepatic abscesses sometimes undergo a caseous change that results in increased viscidity. Frequently the contents are sterile. The presence of liver-cells is not common. Their presence would be diagnostic.

The condition of the walls of the abscess and of the surrounding hepatic tissue will in a great measure depend upon the duration of the abscess. In the early stages there is no sharp line of demarcation, but later on the walls are distinct and ragged, and still later they may be thick and fibrous. The surrounding tissue is often sound, but it may be fatty. Adhesions with neighboring parts may or may not form.

The symptoms of hepatic abscess are usually well marked, but sometimes they are obscure and occasionally are entirely wanting. The onset of symptoms is usually gradual, but occasionally sudden. Of the usual symptoms of pus-formation, rigors, fever and sweating, fever is present in a very large proportion of cases. Jaundice seems to be present more commonly than is usually supposed. An earthy tint of the skin is regarded as of common occurrence. In some cases ascites is present. This may depend upon portal phlebitis or upon dense adhesions. The digestive symptoms are variable. There is usually complete loss of appetite, but occasionally the appetite remains good. Nausea and vomiting are present in some cases. Diarrhea is present in a considerable number. There is little disturbance of the nervous system and of the circulatory system. Disturbances of the respiratory system, such as dyspnea, cough, bronchial râles, and pleuritic friction-sounds, are quite common. Disturbances of the respiratory system may depend upon pain occasioned by breathing; upon pressure of the abscess upward toward the lung; by the bursting of the abscess into the pleural cavity, and by the existence of pleurisy as a complication. Disturbances of the urinary system are uncommon. Emaciation is probably present in a greater or less degree in nearly all cases.

Important evidence is furnished by physical examination of the liver. Pain and tenderness are common. Enlargement of the liver is present in almost all cases. Fluctuation may sometimes be detected. Aspiration may afford diagnostic evidence. Hepatic abscesses may be complicated by localized peritonitis, by adhesions, by hemorrhage into the bowel, by pleurisy, by pneumonia, by infarction of the spleen, by meningitis, by caries of the ribs. It is said that absorption of the contents of hepatic abscess may occur, but such a result is extremely doubtful. Rupture of the abscess is comparatively common. This may occur into a bronchus; into the pleura; into the colon; into the stomach; into the ab-

dominal cavity; outward through the abdominal walls, and into the pericardium.

Caseation and calcification of the contents of hepatic abscesses are rare terminations. In a large proportion of cases death is a direct result of hepatic abscess.

The causes of death are exhaustion, septic infection, peritonitis, destruction of a large amount of hepatic tissue, and complications of other kinds than peritonitis.

The duration of fatal cases may be from a few days to six months. The mean is from six weeks to three months. The treatment is distinctly surgical. The methods that have been proposed are: Aspiration alone; aspiration and subsequent washing out of the cavity with some antiseptic solution through the aspirator-needle; the use of a large trocar and canula alone, the canula being subsequently left in to secure drainage; incision; incision and drainage; incision and washing out with some antiseptic solution with or without subsequent drainage. Practically, the treatment may be reduced to aspiration; incision and drainage; the use of antiseptic washes.

The following are the officers elected for the ensuing year:

President.—Alfred L. Loomis.

Vice-President.—Reginald H. Fitz.

Treasurer.—William W. Johnston.

Secretary.—Henry Hun.

Recorder.—I. Minis Hays.

New Member of Council.—A. Brayton Ball.

Representative in Council of Congress of American Physicians and Surgeons.—William Pepper.

(To be concluded.)

NEWS ITEMS.

Program of the Section of Neurology and Medical Jurisprudence of the American Medical Association.—

Tuesday, June 7th.—Afternoon Session.

1. Address of the Chairman. "Organization and Work of the Section of Neurology and Medical Jurisprudence," Harold N. Moyer, Chicago.

2. "The Relation of Physical Violence to Hernial Protrusion through the Abdominal Walls, and its Medico-legal Aspect," Thomas H. Manley, New York, N. Y.

3. "Consent in Medicine and Surgery," Clark Gapen, Omaha, Neb.

4. "Responsibility in Will-making," Henry A. Chaney, Detroit, Mich.

5. "Aphasia," Philip Zenner, Cincinnati, O.

6. "Hysterical Concomitants of Organic Nervous Disease," C. H. Hughes, St. Louis, Mo.

7. "Infantile Hemiplegia with Aphasia," Joseph Eichberg, Cincinnati, O.

8. "Retinal Excitation of Cortical Origin in Visual Hallucination," C. G. Chaddock, Traverse City, Mich.

Wednesday, June 8th.—Morning Session.

1. "Electrical Execution," A. D. Rockwell, New York, N. Y.

2. "The Electrodes and their Application in Electrocution," George E. Fell, Buffalo, N. Y.

3. "The Reflex Theory in Nervous Disease," L. Bremer, St. Louis, Mo.

4. "Reflex Genito-urinary Neuroses," G. Frank Lydston, Chicago, Ill.

5. "Three Phases of Para-myoclonus and the Use of Phonograph in a Case," Clark Gapen, Omaha, Neb.

6. "Nerve Regeneration after Suture," W. H. Howell, Ann Arbor, Mich.

Afternoon Session.

1. "Syringomyelia: Our Present Knowledge of It," Landon Carter Gray, New York, N. Y.

2. "A Case of Syringomyelia," William C. Krauss, Buffalo, N. Y.

3. "Spinal Localization," Archibald Church, Chicago, Ill.

4. "Lateral Sclerosis, and Its Treatment," W. H. Walling, Philadelphia, Pa.

5. "Heredity in Primary Degeneration of the Nervous System," Sanger Brown, Chicago, Ill.

6. "Surgical Interference with Cerebral Diseases of Childhood," Frank P. Norbury, Jacksonville, Ill.

7. "A Case of Tumor of the Pons in which Tapping of the Lateral Ventricles was done for the Relief of Intra-cranial Pressure," Theodore Diller, Pittsburg, Pa.

8. "Neuralgia of the Abdominal Sympathetic," Harold N. Moyer, Chicago, Ill.

Thursday, June 9th.—Morning Session.

1. "The Relation of our Social Organization to Insanity," David Inglis, Detroit, Mich.

2. "Psychiatric Demography in Chicago," James G. Kierman, Chicago, Ill.

3. "Insanity and Neuroses in Fiction," H. C. B. Alexander, Chicago, Ill.

4. "The Relation of the Paranoiac to Society, and the Responsibility of the Civil Authorities for the Harm He Does," H. A. Tomlinson, St. Peter, Minn.

5. "A Case of Transitory Mania, with Peculiar Sequelæ," G. R. Trowbridge, Danville, Pa.

Afternoon Session.

1. "The Law of Periodicity in Inebriety," T. D. Crothers, Hartford, Conn.

2. "Insanity Following the Keeley Treatment for Inebriety," Richard Dewey, Kankakee, Ill.

3. "Additional Evidences of the Somatic Origin of Inebriety," Eugene S. Talbot, Chicago, Ill.

4. "The Successful Management of the Alcohol Habit," C. H. Hughes, St. Louis, Mo.

5. "On Recent Judicial Evolution as to the Criminal Responsibility of Inebriates," Clark Bell, New York, N. Y.

6. "Delusions as to Locality; a Frequent and Prominent Mental Symptom in Alcoholic Dementia," L. D. Mason, Boston, Mass.

7. "Some Recent Researches and Possible Investigations Regarding the Establishment of Personal Identity," Irving C. Rosse, Washington, D. C.

8. "Angina Pectoris," C. B. Mayberry, Danville, Pa.

Friday, June 10th.—Morning Session.

1. "A Healthy Brain is Necessary to a Free Will," C. G. Comegys, Cincinnati, O.

2. "Moral Insanity and Insane Morality," O. Everts, College Hill, O.

3. "Feigned Insanity," F. W. Harmon, Carthage, O.

4. "How Shall Responsibility be Measured in Criminal Cases," A. B. Richardson, Cincinnati, O.

5. "Some Characteristics of the Human Mind when Placed at a Disadvantage; a Psychological Study," T. L. Wright, Bellefontaine, O.

Program of the Section of Medicine of the American Medical Association.—

Tuesday, June 7th.—Afternoon Session.

1. "A Healthy Brain is Necessary to a Free Will," by C. G. Comegys, M.D., Cincinnati, Ohio. 2. "Epilepsy," by M. M. Leahy, M.D., Chicago, Ill. 3. "Etiology of Specific Disease," by R. French Stone, M.D., Indianapolis, Ind. 4. "Recent Investigations of the Etiology of Diabetes Mellitus," by S. P. Kramer, M.D., Cincinnati, Ohio. 5. "La Grippe," by John E. Link, M.D., Terre Haute, Ind. 6. "A Modified Form of Continued Fever Following the Epidemic La Grippe," by John H. Hollister, M.D., Chicago, Ill. 7. "Positive and Negative Medication," by Bedford Brown, M.D., Alexandria, Va.

Wednesday, June 8th.—Afternoon Session.

8. Address of the Chairman. "Relations of Bacteriochemical Results to Prophylaxis and Therapeutics," by R. T. Edes, M.D., Jamaica Plains, Mass. 9. "Catarrhal Gastritis," by Harold N. Moyer, M.D., Chicago, Ill. 10. "A Case of Amebic Dysentery," by E. P. Gerry, M.D., Jamaica Plains, Mass. 11. "Retained Feces," by Walter S. Christopher, M.D., Chicago, Ill. 12. "Transmission and Behavior of Typhoid Poison as Observed in Country Practice," by Lewis M. Davis, M.D., Farmland, Ind. 13. "A Case of Fermentive Poisoning," by J. T. Axtell, M.D., Hartford, Conn.

Thursday, June 9th.—Morning Session.

14. "Some Non-valvular Heart Murmurs," by N. S. Davis, Jr., M.D., Chicago, Ill. 15. "The Vertigo of Arterio-sclerosis," by Archibald Church, M.D., Chicago, Ill. 16. "The Importance of Position in Examination for Diseases of the Heart," by O. B. Campbell, M.D., Ovid, Mich.

Afternoon Session.

17. "Rheumatic Pleuritis," by E. L. Shurly, M.D., Detroit, Mich. 18. "Conditions of the Pulse and Heart in Phthisis," by N. S. Davis, Jr., M.D., Chicago, Ill. 18. "The Genesis of Pneumonia," by W. W. Pennell, M.D., Fredericktown, O. 19. "The Cardiac Indications in the Treatment of Pneumonia," by J. M. Anders, M.D., Philadelphia, Pa. 20. "Diet and Regimen in Pulmonary Consumption," by Edward F. Wells, M.D., Chicago, Ill. 21. "Additional Evidences of the Value of Forced Respiration, Fell Method, in Opium Narcosis," by George E. Fell, M.D., Cincinnati, O. 22. "A Clinical Note on Rötheln; Period of Incubation," by Charles A. Hough, M.D., Lebanon, O.

Section on Oral and Dental Surgery of the American Medical Association.—The following essayists and essays have been secured:

1. Dr. J. Taft.

2. Dr. H. Gradle, Chicago. "Experiences in Empyema of the Maxillary Sinus."

3. Dr. G. S. Junkerman, Cincinnati. "Oral Manifestations in Metallic Poisonings."

4. Dr. John L. Gish, Jackson, Mich. "Diseases of the Gums."

5. Dr. T. D. Crothers, Hartford, Conn. "On Diseases of the Teeth and Jaws in Inebriates."

6. Dr. J. Smith Dodge, New York. "The Local and General in Dental Pathology."

7. Dr. G. Lenox Curtis, New York. "Restoration of Sight Following Operation for Necrosis of the Sphenoid Bone."

8. Dr. W. C. Barrett, Buffalo, N. Y. "The Condition of the Dentine in Pulpless Teeth."

9. Dr. M. H. Fletcher, Cincinnati. "A Universal Mento-dental Splint, with Report of Case."

10. Dr. E. S. Talbot, Chicago. "Arrest of Development and Decalcification of the Enamel and Dentine."

11. Dr. John S. Marshall, Chicago.

12. Dr. G. W. Weld, New York. "The Treatment of Anemia by a New Preparation of Iron, Illustrated by the Hemoglobinometer."

The Medical Society of New Jersey will hold its next annual meeting at Atlantic City, on June 28 and 29, 1892. A special train will leave Camden on Tuesday at 12.15 P.M. for the accommodation of those who may wish to attend the meeting.

The Mississippi Valley Medical Association will hold its eighteenth annual session at Cincinnati, on October 12, 13, and 14, 1892.

Books and Pamphlets Received.

Orthopedic Surgery as a Specialty, and Diseases of the Hip-joint. By Arthur J. Gillette, M.D. Reprint, 1892.

Medical Orthoepy. By J. F. Oaks, M.D. Reprint, 1892.

Empiricism: Rational Practice, etc. A Lecture to Medical Students. By Charles S. Mack, M.D. Reprint, 1892.

Report of the Wills Eye Hospital for 1891. Philadelphia, 1892.

Ataxia. A Clinical Lecture. By J. T. Eskridge, M.D. Reprint, 1892.

Personal Experience of a Physician. A Review of "Christ and the Temperance Question," in *The Christian Union*. By John Ellis, M.D. Pamphlet. Philadelphia: Hahnemann Publishing House, 1892.

Spectacles and Eye-glasses; Their Forms, Mounting, and Proper Adjustment. By R. J. Phillips, M.D. With 47 Illustrations. Philadelphia: P. Blakiston, Son & Co., 1892.

Eleventh Annual Report of the State Board of Health of Illinois, for the Year ending December 31, 1888. With an Appendix Containing the Official Register of Physicians and Midwives, 1892. Springfield, Illinois, 1892.

Studies upon Injuries of the Kidney, Nephro-lithotomy, and Nephrorrhaphy. By Aug. Schanhuer, M.D. Pamphlet. Louisville, 1892.

The Present Status of Homeopathy, and Its Future. By H. R. Stout, M.D. Reprint, 1892.

The Epidemic of Yellow Fever in Jacksonville, Fla., in 1888. By H. R. Stout, M.D. Reprint, 1890.

The Medical Specialists. By L. H. Taylor, M.D. Reprint, 1892.

Cases and Treatment of Mastoid Disease. By Lewis H. Taylor, M.D. Reprint, 1892.

Lessons of Public Sanitation and Their Historical Development. By Dr. Max Schottelius. Specially Translated by Lewis H. Taylor, M.D. Reprint, 1892.

INFECTIOUS DISEASE IN CITIES; WITH ESPECIAL REFERENCE TO DENVER.

BY HENRY SEWALL, PH.D., M.D.,
ASSISTANT HEALTH COMMISSIONER,
DENVER, COL.

STEP by step science is increasing our knowledge of etiology by adding to the list of microbic diseases. To-day we admit the parasitic origin of maladies that, ten years ago, we thought typically non-parasitic. To-morrow we may include in the microbic list ailments that now give no hint of their infectious nature. A recent writer[1] concludes from his personal researches that, to the list of proven infectious diseases, we must now add articular rheumatism, pharyngitis, tonsillitis, intercostal neuralgia, and some forms of sciatica.

Though science has proven the infectious nature of many diseases, medical art has, in most cases, failed in settling on definite modes of treatment, still less in intelligently annulling the conditions under which these diseases flourish.

In the present state of knowledge, we are justified in stating that all infectious diseases are each caused by a distinct chemic or anatomic entity that enters the body from without. If this morbific agent be kept out of the body, no sickness results; if it be allowed to penetrate the body, the effect, whether simply negative or positive in sickness or death, depends altogether on the relative vital resistance of the invader and the invaded. We can properly go a step further, and declare that the causes of infectious diseases are living microörganisms that, as can be proved by laboratory experiment, need for their development and activity certain conditions of heat, moisture, illumination, and food-supply.

We may generalize still further: It is well known that the processes of putrefaction and fermentation are simply the effects of the development of certain microörganisms, and are the signs of living agents operating on dead matter—as Huxley puts it, "Putrefaction is a concomitant, not of death, but of life." The microörganisms of disease need for their development a food-supply of decomposable or, roughly speaking, putrescible matter. Every community is continually producing quantities of such matter in the animal and vegetable wastes incident to living; in the kitchen garbage and slops, in fecal matter and in urine, in sweat and in the vapors of respiration. It follows that the more completely the soil and the drinking-water of a neighborhood are saturated with these putrescible waste-matters, the more likely it is that disease-germs once dropped upon them will abide and flourish—not that so-called "filth" *creates* infectious diseases, but that it preserves and nurtures them when once they are implanted. This appears a simple and self-evident proposition, yet it is for the practical sanitarian a bulwark of defence that alone stands between him and the assaults of those whose self-interests his duties compel him to disturb.

Filth harbors disease. We must fix on this general fact as the outcome of all human experience. For the more we consider the conclusions of different scientific investigators concerning the special conditions that determine various diseases, the more confused and uncertain must our ideas become in proportion as we give weight to authorities. It is not long since Koch and his corps of assistants, working in Egypt and in India, proved to their own satisfaction that the cholera, endemic there, was produced by organic contamination of drinking-water, and, moreover, that the specific agent of infection was a demonstrable microörganism, the so-called "comma bacillus." On the other hand, Dr. J. M. Cunningham, who for thirty-eight years practised medicine in India, and for twenty years was chief of the Indian Sanitary Bureau, with unequalled advantages for comparative observation, says, in his work on the subject, that no outbreak of cholera in any part of India has been shown to have etiologic relation to the drinking-water, and when such a relation seemed to exist, closer investigation showed the error of the belief.[1]

Again, the opinion is world-wide that there is a causal relation between the condition of the drinking-water and the development of typhoid fever in a community. The evidences and authorities in favor of this belief are almost numberless. Yet for years one of the foremost sanitarians of the age, Von Pettenkofer, of Munich, has declared against the connection between the water ingested and the occurrence of typhoid fever.

Not long ago, Dr. Kratter[2] published the results

[1] E. Reger: Zur Lehre von den Contagiösen Infectionskrankheiten. Berlin, 1890

[1] Quoted from Kratter, "Studien über Trinkwasser u. Typhus." Gratz, 1886.

[2] Kratter: Loc. cit.

of a series of investigations that he had carried on for five years in the town of Gratz, on the connection between the purity of the drinking-water and the development of typhoid fever. Kratter found no such relation; on the contrary, he discovered that the greatest number of cases of typhoid fever developed in neighborhoods supplied with the purest, and the smallest number in districts furnished with the impurest drinking-water. On the other hand, Kratter found that the people living in a part of the city in which the underlying bed-rock rose in a ridge toward the surface, giving a free subsoil drainage, though their habits were ultra-filthy, and though they used the chemically bad drinking-water, were singularly free from typhoid fever. An American hygienist, Professor V. C. Vaughan, of the University of Michigan, after an exhaustive study, chemic and bacteriologic, of a number of specimens of drinking-water that were supposed to have caused typhoid fever, was unable to show in them the presence of any specific element of contagion.

On the other hand, v. Födor, one of the ablest living bacteriologists, working in the city of Budapest, found a close relation between the condition of the drinking-water and the development of cholera, typhoid fever, diarrhea, and smallpox; while no such relation was apparent in the development of intermittent fever, scarlet fever, diphtheria, or mumps.

The apparent discrepancies in the conclusions of advanced scientific workers will all be harmonized in time. In the meanwhile, we may rest secure in the belief that a healthy community in a healthy neighborhood presupposes pure food, pure water, pure air, pure soil; and the best provisional definition of purity is the absence of the waste-matters produced by organized life, and of deleterious chemicals of whatever sort.

Though a closer study of micro-biology shows that every specific pathogenic microörganism grows best under certain definite conditions of heat, food, and moisture, it is a broad fact of inestimable practical value, and one that has been established by the experimental researches of sanitarians in the last two decades, that the sanitary measures that are successful in limiting the spread or preventing the development of any single infectious disease, as, *e. g.*, cholera, are, at the same time, efficacious against all other infectious diseases.[1]

Using this conclusion as a starting-point, we are prepared to enter upon a study of the conditions that determine the existence and spread of infectious disease in Denver—not by theoretic generalizations, but by exact observation of the varied conditions under which flourish individual diseases. In order to carry out such a research, we must have accurate information as to the total number of cases affected with a definite disease, and their distribution in the city. There are only two infectious diseases that are sufficiently common to make them of great importance, and concerning which our imperfect laws are sufficiently stringent to allow us to rely upon a full report of cases—namely, scarlet fever and diphtheria. In some other countries, as in England, probably on account of peculiar meteorologic conditions, whooping-cough stands among the most fatal infectious diseases, but with us it seems to be comparatively unimportant.

The vital statistics of Denver regarding scarlet fever and diphtheria, show that in 1890, with a census population of 106,713, there were reported 276 cases of scarlet fever, with a mortality of 4.7 per cent.; and 695 cases of diphtheria, with a mortality of 31.6 per cent.

In 1891, with an estimated population of 113,874, there were reported 256 cases of scarlet fever, with a mortality of 6.9 per cent., and 440 cases of diphtheria, with a mortality of 32.9 per cent. One is startled at the high mortality due to diphtheria. But the statistics of cases admitted to the hospitals of Paris between 1866 and 1890 show a much higher death-rate;[1] and in a recent epidemic in the town of Heywood, in England, more than 50 per cent. of the cases reported died.

I think it may be taken for granted that absolute accuracy in any table of vital statistics is impossible. Clerical errors are prone to arise in computations involving thousands of complex numerical data; the conclusions presuppose a full report of all cases, and, what will be probably forever hopeless of attainment, a uniform diagnosis of the true nature of maladies.

Thus, in the Paris hospitals, between 1866 and 1890, the absolute mortality from diphtheria increased about fivefold, though the proportion of cases ill with the disease increased nearly tenfold. A somewhat similar increase of diphtheria, within the period mentioned, is recorded throughout France. In England, since the national introduction of definite sanitary measures, especially since 1875, there has been a remarkable diminution in the rate of mortality from infectious diseases, with the exception of diphtheria.

The figures show that, in this disease, there has been both an absolute and relative increase of mortality. A writer in the *Lancet* has recently offered an explanation for this strange result by calling attention to the fact that, with the apparent increase of diphtheria, there was more than a cor-

[1] Revue d'Hygiene, 1891, p. 45.

[1] Idem, 1891, p. 687.

responding decrease in the reported cases of scarlet fever and various throat-affections—leading to the suspicion that, with the more perfect development of the art of diagnosis, or, perhaps, as the result of a change in medical fashion, many diseases now regarded as diphtheria were formerly ascribed to other causes.

The first essential to any intelligent measures for the repression of infectious diseases is an inquiry into the manner of their propagation and dissemination.

We are justified in making the dogmatic assertion that infectious diseases may be distributed in two different ways. First, the disease may be transferred directly from the sick person to the body of one who is well, *i. e.*, through personal infection. Second, the contagium, or disease-germs, cast out by the patient may remain indefinitely in the room or on the clothes, or other articles surrounding him, and, after a longer or shorter time, find entrance into the bodies of persons coming in contact with them. Again, it can hardly be denied that disease-germs cast off from the body of a sick person come at once under conditions that are either favorable or unfavorable to their preservation. Fortunately for the maintenance of our species, the usual conditions in which these germs find themselves on being cast off from their host, are unfavorable to their life. Thus, it is sufficiently proven that sunlight is a powerful germicide; also, oxygen with, in some cases, the assistance of moisture, and, in others, of dryness, destroys the pathogenic organism. Occasionally, however, the disease-germs emanating from the body of the sick fall into an environment favorable to their life, or on a soil suitable to their reproduction. Here, then, the respective disease becomes endemic; and it is of the first importance for us to know the external conditions that favor the multiplication of each micro-organism.

To summarize the statements just made: The disease-germ has two loci of propagation—first, outside of the body, in soil suited to its growth, in which case its effects are invisible to us; second, inside of the body of lowered physiologic resistance, and then disease is the result.

It may be mentioned in passing that all authorities seem to agree that the bacillus of typhoid fever lives best in moist ground, somewhat under the surface, and is quickly killed by desiccation and sunlight; also, what is especially important in this discussion, that the germs of diphtheria live on the surface of the ground, and that moisture seems necessary to their reproduction.

Fecal matter is said to constitute particularly good soil for the preservation and propagation of most disease microörganisms. On the other hand, ordinary soil has extraordinary powers of self-purification, and soon destroys the vast majority of micro-organisms that fall upon it. This is the property made use of in the purification of water by interrupted filtration. It is generally admitted among bacteriologists that the number of microörganisms in the soil diminishes as we dig below the surface, and that at a depth of from eight to ten feet they totally disappear.

Next in importance to the determination of the conditions under which pathogenic organisms are preserved and reproduced, is the question as to the manner and circumstances amid which the infectious principle enters the bodies of its victims. I do not hesitate to assume, again, that the infectious principle is a living microörganism.

We are well within the bounds of proven fact when we assert that each microörganism has a cycle of existence, during the various stages of which it shows differences of resistance to the action of destructive agencies. It is, perhaps, a permissible assumption, that, at certain stages of its development, the pathogenic germ has unusual propagating energy, and it is while in this physiologic condition that it would prove most likely to cause infection.

Apropos of this question, it would be exceedingly interesting to review some conclusions recently expressed in a remarkable work on the dissemination of infectious diseases, by Dr. E. Reger, physician to the Military Training-school at Potsdam, Prussia.[1]

For a number of years Reger has been in a position to make exact clinical observations on the cadets in training at the military school mentioned. The conditions of discipline appear to have been such that the hourly distribution and associations of the cadets were known, so that the path taken by any infectious disease in its progress could be accurately determined. Under these circumstances Reger studied the dissemination of a number of infectious diseases, including diphtheria, scarlet fever, measles, and mumps.

Naturally, as soon as the first symptoms of infectious disease appeared in any cadet, the patient was at once removed to and maintained in the hospital. It was usually found, however, that when a certain cadet became ill with a disease that proved to be infectious, other cases afterward appeared, and always among those who had been in closest personal relation with the original victim.

This is the briefest possible statement of the grounds on which Reger makes the important announcement that "infectious diseases are spread by personal contact with sick persons, and not, usually, by contact with infected articles or places." Moreover, according to Reger, it is either in the period

[1] Op. cit.

of commencement or at the acme of the disease that the patient is most dangerous as a source of infection. In the scaling stage, or declining period of the disease, the danger of infection is comparatively small.

Reger's idea is that the infecting microörganism has most virulent nutritive and propagating powers at only a definite stage in its cycle of existence, and this is when it is actively multiplying at the commencement or height of an infectious attack. The microörganisms contained in the scales of desquamation have already nearly lost their vitality, and but feebly attack any physiologic surface on which they may fall.

This work appears to be an important contribution to the science of epidemiology, and the general conclusions reached are not necessarily invalidated by the exceptions to their truth that will at once suggest themselves to every mind. One other conclusion of Reger's is appropriate to our subject, namely, that in nearly all cases infection is of a mixed type—in other words, in most maladies various pathogenic organisms of different specific natures are active within the body, and only as one or another of them gets decidedly the upper hand in its development can we definitely characterize the disease as diphtheria, scarlet fever, etc. Both at the beginning and at the ending of an epidemic, especially, other microörganisms come more to the foreground, and we have tonsillitis, sore-throat, etc. Only one disease, according to Reger, constantly breeds true and reproduces its like in individual after individual, and that is measles. The course of other infectious diseases, as diphtheria and scarlet fever, in a succession of persons who have serially inoculated each other, is interrupted by diseases that are, in general, similar to them, but by no means have their specific character.

In the foregoing lines I have endeavored to state, though in the merest outline, some general considerations that must be borne in mind in any intelligent attempt to cope with infectious disease.

The first fact to determine, in studying the influences that engender contagious diseases in Denver, is the local distribution of the maladies.

This has been most satisfactorily accomplished by marking on a map of the city the exact location of each case of infectious disease as it is reported. In this way are marked on the same map, in different colors, all reported cases of diphtheria, scarlet fever, and typhoid fever. Separate maps are used to show the distribution of disease for each month, and also for the quarter, half, and full year. A glance at such a map indicates at once a tendency of the diseases to fall into groups or follow certain neighborhoods. The cause of this grouping is one of the most difficult problems with which we have to deal, and its discussion will be, for the present, delayed. It is the present policy of the Health Department to submit all premises on which the presence of infectious disease is announced to thorough sanitary inspection within a month after the case has been reported.

The inspector for this work is a medical man, chosen with especial reference to his tact and address. He is furnished with a note-book having printed on one side of each sheet the following list of questions to which written answers are returned:

No. —. Date —. Name —. Residence —. Number in family —. Habits —. Previous sickness in family —. Disease —. Time of —. Number affected —. History —. House: age —; frame or brick —. Number of floors —. Number of rooms —; living, sleeping —; bath, closet, kitchen sink, connected with —. House heated by —. Rooms ventilated —; dry, damp —. Plumbing —. Cellar: size —; walls —. Floor: damp, dry —; ventilated —. Ventilation under house —. Previous sickness in house —. Premises: number of lots —; proportion covered —. Sewer connection —. Cesspool: leaking, tight —; privy vault: leaking, tight —; hopper, plunger —. Water-supply —. Milk-supply —. Ice-supply —. Disposal of slops —; of garbage —. Adjacent premises: condition —, alley —, ditch —, slope of surface.

On the reverse side of the sheet is a space for a diagram of the premises, and for remarks appropriate to the special case; these are frequently of more value than the answers to the printed questions. Every inspection is numbered and properly listed in a card catalogue so that it may be referred to at a moment's notice. It may be remarked, in passing, that a somewhat similar inspection record-book is in use by the plumbing inspectors, and another appropriate to a full sanitary investigation of the dairies supplying milk to the city.

There have, thus far, since August, 1891, been recorded 500 general sanitary inspections of different premises harboring contagious disease. In 237 cases the inspection was made on account of the occurrence of scarlet fever, and in 263 cases because of diphtheria—that is, 47.4 per cent. were cases of scarlet fever, and 52.6 per cent. of diphtheria.

Any conclusions based on the data thus obtained must be drawn with exceeding care, lest they have to be reversed with the wider knowledge of increased experience.

The first essential to the healthfulness of a household would seem to be cleanliness in the habits of the people. It is believed that a tolerably correct idea of the general mode of life of a family, as affecting its health, can be gained even in the limited time devoted to an official inspection. Con-

cerning the habits of households afflicted with infectious disease our statistics show that, in the case of scarlet fever, 37 per cent. of the families are represented as of good or clean, and 62 per cent. as of bad or filthy habits; while in the diphtheria households only 29 per cent. are good and 70 per cent. bad; that is, on the whole, the better class of people incurs scarlet fever, and the lower class suffers from diphtheria.

The material of which a house is built would seem to have some relation to its sanitary condition. Of the houses harboring scarlet fever we find 79 per cent. brick, 15 per cent. frame, and less than ½ per cent. tents; while in those with diphtheria, 72 per cent. were brick, 25 per cent. frame, and 3 per cent. tents. Tent life affords no protection against disease when, as is usually the case, people living in this way have habits that are ultra-filthy. We are, however, at once struck by the high percentage of frame houses, particularly in cases in which diphtheria has occurred. In the thirty-first sewer district, containing probably as large a proportion of frame houses as any similar area in the city, it has been found by actual count that the frame houses constitute less than 25 per cent. of the total number of dwellings; but more than 25 per cent. of the cases of diphtheria reported occurred in frame buildings. It may be added that diphtheria seems particularly common and especially virulent in cases in which old boards, soaked with moisture, are found either in or about the infected house.

The ventilation of the apartments of a house has a very broad sanitary bearing as determining the physiologic resistance of the occupants against any disease. We find recorded that in the scarlet fever houses the rooms were well ventilated in 41 per cent. and badly ventilated in 58 per cent. of cases; while in the diphtheria houses the ventilation was good in only 32 per cent. and bad in 67 per cent.

From time immemorial, dampness in living and sleeping apartments has been regarded as evidence of insalubrity. In this dry climate, it is a point of especial significance. According to the view of modern science, dampness is necessary to the reproduction of pathogenic organisms, which are, moreover, held in its grasp and prevented from escaping. Of the scarlet fever houses, 73 per cent. are recorded as dry, and 26 per cent. as damp. Of the diphtheria houses only 67 per cent. are dry and 32 per cent. damp.

We now come to a sanitary question that seldom seems to trouble the artistic mind of the architect, and still less disturbs the practical nature of the contractor and builder. Every house set upon the ground acts as a chimney for the gases and vapors in the soil. The heated air of the house in rising sucks from the soil the gases contained in it, and these permeate the rooms of the dwelling to take part in supplying the respiratory needs of its occupants. The means for this communication between the house space and the ground space are abundant. In the lower rooms there can frequently be demonstrated a strong breeze blowing into the rooms from the space beneath the floor through the cracks between the ends of the floor-boards and the side-wall.

This matter will, perhaps, seem of greater importance when reference is made to those influences that cause pollution of the soil beneath a house. In the meanwhile, it is an interesting observation, made by an English hygienist, that, under the best conditions, every house in a large city is enveloped in an atmosphere charged with impurities that are deposited on the neighboring surfaces that can retain or absorb them. In other words, an inhabited house, like a living body, is continually exhaling noxious matters. Evidently the way to avoid breathing this foul and disease-breeding ground-air is to coat the ground and walls under the house with cement, or better, asphalt, impervious to air and moisture, and then to thoroughly ventilate all the space under the ground floor. In the houses noted in our records, there was seldom a cellar under the whole of the house, and the cellar, when present, rarely afforded efficient ventilation for the remaining ground-space.

The *data* are as follows:

In the scarlet fever houses there was no cellar in 18 per cent.; the cellar floor was of dirt in 69 per cent., of cement in 16 per cent., of board or brick in 14 per cent. The cellar was dry in 20 per cent., and damp in 79 per cent. There was no ventilation under the house in 43 per cent.; it was poor in 39 per cent., and good in 17 per cent. In the diphtheria houses the condition was worse, namely: No cellar in 23 per cent.; dirt floor in 68 per cent., cement in 17 per cent., board or brick in 14 per cent.; the cellar was dry in 20 per cent., and damp in 79 per cent.; there was no ventilation under the house in 67 per cent., it was poor in 16 per cent., and good in 16 per cent. In most cases the nature of the surroundings aroused strong suspicions that the dampness was the result of soakage from leaking cesspools or from slops thrown upon the surface; it is common to find a fungous growth upon the cellar walls.

It is manifestly a matter of the very first sanitary importance that the sewage and garbage should be completely removed from the neighborhood of all dwellings. In large communities there seems to be but one efficient mode of disposal of fecal matter and slops, and that is by means of a well-con-

structed system of sewers. The fate of the garbage is largely determined by the habits of the members of the community. It seems impossible to educate the mass of the people to consuming it by fire. Until a short time ago, Denver was very inadequately sewered; but there is excellent prospect that, within a year, only a small portion of the city will lack this means of filth-removal. Even in the sewered parts of the city the proportion of houses connected with the sewer amounted in June, 1891, to considerably less than 25 per cent. For the most part, the house-wastes, when not thrown upon the ground, were conducted to cesspools and privy-vaults, which almost invariably leaked, saturating the ground with the best of germ-propagating food.

As regards sewer-connection, our figures show that, of the scarlet fever houses, 36 per cent. were so connected and 63 per cent. not connected; 33 per cent. had neither cesspools nor sewer-connection; while 30 per cent. had cesspools, of which 91 per cent. leaked. In the diphtheria houses, only 22 per cent. were sewer-connected; 49 per cent. had neither cesspools nor sewer-connection; 28 per cent. had cesspools, of which 94 per cent. leaked. These figures, at least, indicate that there are no virtues in an unsewered district, as such, that protect that district from disease.

It was the first inclination to believe that these data definitely proved the superior sanitary advantages of sewer-connection, but, on comparing with the total number of houses in the thirty-first sewer district the number of those that had been connected with the sewer up to June 1, 1891, it was found that only a little more than 24 per cent. of the houses were so connected; on the other hand, of the houses in the thirty-first district examined on account of the presence of infectious disease, it was found that more than 41 per cent. were connected with the sewer. This result impresses upon us an important corollary to the general sanitary law of waste-removal, and that is, that though efficient sewerage is, for a large community, the best means yet discovered for the disposal of slops and fecal matter, there may be such radical defects in the work of the drain-layer and plumber that the sewer becomes an actual menace to health.

There are two principal ways in which sewer-connection may become a positive danger. The plumbing in a house, unless constructed in a most conscientious manner by workmen possessing a considerable amount of trained knowledge, is almost sure to result in a set of apparatus easily made foul and difficult to clean, and in traps that readily lose their seal and admit into the rooms the gases from the sewer. We hear a great deal about "sewer gas," and it is a most convenient cudgel to arouse the apprehension of householders whose premises need sanitary remodelling; for people are to be convinced by things visible, palpable, and odoriferous, if not by the logic of scientific facts. Yet sewer-gas is, chemically, not a very poisonous agency, and it may be doubted that it often produces serious evils, except when it rises in bubbles from fermenting or agitated sewage and carries with it a spray of moisture containing pathogenic microorganisms. No one can predict when such a catastrophe may arise, and, harmless or not, none but an imbecile would willingly permit the admixture of sewer-gas with the air to be breathed by his household. Probably a more serious defect than insufficient plumbing within the house arises from the leaky condition of the soil-pipes on or under the surface of the ground beneath the house. Nearly all the soil-pipes in Denver that were laid previously to two or three years ago, were constructed of short pieces of tile, cemented together. Sooner or later, such tile-drains begin to leak at their joints, gradually saturating the soil beneath the house with fecal matter that, as already pointed out, is one of the best of all media for the preservation, if not the propagation, of pathogenic organisms, and is the substance that, above all others, is likely to contain them.

Moreover, the soil-pipe often runs very near, or even within, the fresh-air duct of the furnace, through which, in winter, air is supplied to the house for the purposes of warmth and ventilation.

It may be noted, in passing, that a serious menace to the health of many families resides in the structure and position of the channel conveying air to the furnace. This duct often opens on the surface of the ground in such a manner as to become a receptacle for filth, and it is almost invariably so leaky as to permit the free entrance of ground-air from beneath the floor.

As regards the plumbing and drains in and under the houses of Denver, suffice it to say, that not only do they too often exhibit the most glaring sanitary defects, but it is only at the price of eternal vigilance on the part of householders and sanitary officers that we can hope to avoid the repetition and perpetuation of this defective work and workmanship.

This statistical review will be brought to a close by a consideration of the source of the water-supply in the infected premises. Only one fact with regard to the water-supply seems especially significant. Seventeen per cent. of the houses infected with scarlet fever, and not less than 30 per cent. of those infected with diphtheria, depend on wells for their washing and drinking water.

These wells are never driven below bed-rock, and must receive all manner of surface-drainage. When

the sewers were laid in West Denver, it was found that the water in the wells of that section fell to the level of the sewer line. This, taken in connection with the fact that chemic analysis almost invariably shows the presence in well-water of a much higher percentage of chlorides and nitrites, the common result of fecal contamination, than does the city water, sustains the conclusion that well-water is, for the most part, dangerously polluted with the filth of surface-soil.

The foregoing sketch is but an incomplete and preliminary representation of the more salient facts in the sanitary problem of Denver. It nevertheless seems that certain conclusions of importance can safely be drawn from the data recorded. It appears, in the first place, that there is an important distinction between the habits, so to speak, of diphtheria and scarlet fever, in that the former is more fixed and the latter more nomadic in its distribution.

The more fatal disease, diphtheria, clings to certain houses and neighborhoods in which definite investigation has shown the surroundings to include the sum of those conditions that common experience has denominated unsanitary. The worse the sanitary state of the locality (not necessarily the worst to superficial observation) the more numerous are the cases, not only of diphtheria, but of typhoid fever and other infectious diseases.

Notwithstanding the conclusions of a recent writer in THE MEDICAL NEWS,[1] we are justified in still holding to the belief that diphtheria is essentially a filth-disease; its germ abides in, and is nourished by, polluted soil; and with it we have usually found associated the evidences of other infectious diseases.

The milder disease, scarlet fever, appears to be more dependent on actual contact between person and person for its transmission. Though most cases of scarlet fever, like those of diphtheria, occur in localities in bad sanitary condition, a large proportion is distributed in neighborhoods and in houses of which the sanitary condition is, at least, better than the average.

In some years there seems to be a close relation between the number of cases of scarlet fever reported and the duration of the school-term. With regard to diphtheria, however, such an association is by no means so apparent.

In the second place, if we but admit the truth of the sanitary dictum that "filth breeds disease," it can hardly be disputed that the facts recorded in the foregoing statements show abundant explanation of the existence and propagation of infectious disease in Denver.

[1] "Are Diphtheria and Typhoid Fever Filth-Diseases?" Chapin, THE MEDICAL NEWS, 1892, p. 312.

A NATIONAL SYSTEM OF SANATORIA—A PLEA AND A PROPHECY.

BY SAMUEL S. WALLIAN, A.M., M.D.,
OF NEW YORK.

IT ought to be a remarkable assertion that up to this time there is in this country not a single health-institution, invalid-retreat, or sanatorium, founded, constructed, and conducted in full and perfect accord with recent advances in medical and sanitary science; yet it is extremely doubtful whether any intelligent apologist will either contradict or seriously attempt to refute the assertion. Hence, it is impossible to avoid the conviction that, in the light of the fairly revolutionary biologic and etiologic discoveries and demonstrations of the past ten or fifteen years, we shall soon be compelled to radically revise or perhaps totally discard the present system, if system it may be called, of locating, building, and managing sanatoria.

With few exceptions, existing institutions of this kind were built and are conducted on theories and practices, or possibly only on traditions that, with comparatively few and very conservative modifications, have prevailed for generations past. Many of them were built and equipped, and are operated solely from the sordid motive of money-making. Some of them are merely the pronounced and arbitrary exponents of the medical fads and hobbies of physicians who rely on some one special or exclusive treatment, or who expatiate enthusiastically concerning the panacea of climatic influences, or the miraculous virtues of some gushing spring of earth-heated or mineral-tainted water. Others are simply invalid-hostelries, palatially and ostentatiously equipped and appointed structures, in which the fashionably sick, lame and lazy are periodically massed and charged unconscionable rates for the privilege of inhaling each other's breath, exchanging social scandals, or condoling with each other over real or hypochondriacal ailments. Millions are annually spent—for the most part squandered—by the invalid and semi-invalid classes at these resorts, either fashionable or advertisement-famous, the benefits realized being principally from the travel, the change of diet and surroundings, and the consequent mental diversion incurred.

Primarily, even as to location, it is evident that many, perhaps a majority of existing health-institutions were founded at sites selected more on account of the immediate proximity of some traditionally famous "mineral" springs, or with a view to fashionable accessibility and likelihood of popular patronage, than on account of sanatory, climatic, or hygienic considerations. In the matter of their construction and arrangement, the evident aim has been to secure the largest accommodating capacity possible for the amount of capital involved.

True, there is a margin of excuse in the fact that many, in fact nearly all, were built before sanitary science had reached its present status; but there are too many instances in which there has been a palpable disregard of known sanitary laws. In the general plans and arrangement, business expediency has been carefully considered, and commercial necessities have been made to cover a multitude of unsanitary sins. In consequence they are really *hôtels des invalides*, but in no accurate or modern sense are they sanatoria. Their managers are selected, not according to their competency as physicians and sanitarians, but for their natural aptness and tact as landlords. Considering existing standards and the incongruous conditions and demands to which they are obliged to cater, it is surprising to see how relatively well some of them acquit themselves. When they are proprietors they are expected, above all other considerations, to make money for themselves; and, when merely salaried employés, for a mercenary capitalist or some heartless as well as thoughtless stockholders. They must, therefore, trim their sails and shape their courses to meet the whims and vagaries of a fickle and unintelligent popular fashion. It is quite time that this fashion, which is almost never based on real faith or confidence, rarely even on tradition, but usually on some contagious whim, should be intelligently coached and directed, instead of being systematically and annually flattered and fostered.

The divergence of these institutions from hygienic and scientific ideals is more glaringly apparent in the matter of construction than in any other particular. With so few exceptions that they are scarcely worth mention, they are all either hostelries or hospitals. As such they are fairly suited to the temporary entertainment of either guests or patients, but they are not at all adapted for the proper or prolonged treatment of chronic invalids. Hotels and hospitals are both very necessary; but as a hotel is never a legitimate or permanent home, so a hospital can never be made a proper or efficient sanatorium.

If it were necessary to adduce evidence to confirm this assumption, it would suffice to cite the indisputable fact that all recent scientific and hygienic demonstrations unmistakably point in the direction of *segregation* as opposed to *congregation*, in the matter of housing and treating chronic invalids. In the present state of society, hotels and hospitals are indispensable; but it matters not how palatial or well-appointed they may be, both are merely sanitary compromises, since in them the plan of isolating or dissociating patients is not and cannot be made possible.

In the matter of treating chronic invalids, it is now admitted by a growing consensus of authoritative opinion that there are no specifics, that old-time dosing has at best but a very limited province, and that a skilful and scientific adjustment of all salutary natural agencies does most, and often all that is done, or that can be done, toward the relief and betterment of the patient. It must be understood that the term "natural agencies" is very comprehensive, including at once all those forces, influences, and resources of nature now so freely and generally invoked by the modern physician and sanitarian; climate, altitude, nutrition, asepsis, general hygiene, hydrotherapy, electricity, pure air, sunshine, exercise, massage, the moral and social environment, etc.—an almost interminable list.

How many of the existing "health" institutions are either situated or constructed so that the essential details of any such comprehensive or in fact of any rational system of treatment can be even approximately carried into effect? Taking into consideration the system or rather un-system under which they were organized, and the absence, at the time they were built, of some of our present sanitary light, it must be admitted that some existing institutions are doing decidedly creditable work; but it is evident that, hampered by that system and primary drawback, they can never hope to approximate an ideal standard of attainment. And while it is freely admitted that there are painstaking and conscientious workers in this field, none better than they realize their utter but inevitable limitations.

Another very serious drawback to the existing state of things is that individualized institutions, like any other independent organizations, are naturally, and must always remain, competitors. As a consequence they are in a commercial, and altogether too often in a professional, sense antagonistic. Each is duly bound to herald its own claims and asserted advantages as wholly peculiar to itself, and decidedly superior to any found elsewhere. In this imperfect world this spirit inevitably leads to detraction and misrepresentation, fosters professional jealousies, and results in frequent instances in patients being induced to seek climates and locations manifestly unsuited to their individual conditions or circumstances.

Still another considerable objection to the existing system is its relative costliness. "Well-appointed" hostelries necessarily entail heavy expense in the matter of show structures and extravagantly luxurious furnishings and equipments. It follows that so long as so-called sanatoria are virtually patterned after merely high-toned hotels, well adapted to the entertainment of miscellaneous guests, including semi-invalids, social adventurers and malcontents, periodic travellers, and that annually increasing class of the discontented victims of mere *ennui*, whose time and, possibly, money both hang heavily on their hands; in short, until the

newer demands in the matter of construction and arrangement of these institutions shall have been carefully considered and practically met, this item of comparatively needless expense is implied and cannot be avoided.

That existing "health-resorts" are liberally patronized, and that many of them are annually compelled to enlarge their facilities, by no means proves that they are in any sense model institutions, not even that they are passably unobjectionable, hygienically speaking, as popular resorts. Their success is more a matter of advertising tact and fashionable preference than from any valid claims for sanatory merit. This is sufficiently evident from the quite too frequent reports of infectious and easily preventable epidemics that somewhat more than rarely occur at these places. At the same time, the immense patronage annually and eagerly accorded to them, abundantly proves the existence of a persistent and steadily growing demand for properly planned, equipped and conducted sanatoria.

How can the requirements of modern science be met? The first and most important step is unquestionably in the direction of the segregation or semi-isolation of sick people. No set arguments are needed to substantiate this position; every microscopic revelation in the biologic field for the last ten years has reasserted it. The laws of antisepsis, all the discoveries pertaining to the processes of infection, contagion and disinfection corroborate it; the necessity for it has become pronounced and unmistakable. To accomplish it, in any thoroughly practical and effective sense, implies the cottage and dormitory plan of building, both of hospitals and sanatoria. Happily, the sanitary arguments are not the only ones to be adduced in favor of this plan. By this plan the necessity for massive, palatial, excessively ornate—and, therefore, unnecessarily costly—structures is at once obviated. It calls for a central rendezvous and supply-house, which may be very simple in design and yet architecturally tasteful, surrounded at sanitarially safe distances by groups of detached and preferably *portable* cottages, varying in design and finish from the simplest rusticity to the most ornate, to suit the tastes and purses of every grade of patrons; but which, above all else, must be perfectly adapted to the uses and purposes for which they are designed.

It is assumed that the requirements of economy as to original outlay are decidedly in favor of the cottage plan of building; but even if the reverse were shown to be the case, if rational deductions from well-demonstrated and now generally admitted data are to receive practical recognition at the hands of sanitarians and the general profession, it is quite evident that in the light of recently demonstrated sanitary science, the massing of invalids in large single edifices can no longer be tolerated. Furthermore, measured by the question of practical results, the problem of ultimate economy can have but one solution, and that in favor of the cottage plan, no matter what might be indicated by the figures of the original outlay.

Two vitally important questions remain to be considered: First, how to effectually eliminate the disastrous element of undignified and unscrupulous competition. Second, how to formulate a practical business basis on which to organize any implied or proposed "new departure."

As a possible and apparently feasible solution of the first I suggest the organization of *A National System* (or Chain) *of Sanatoria*, the same to be planned and conducted under one coördinate and coöperative management, if the term "coöperative" may be used in its higher sense and without prejudice on account of its much abuse, and if medical politics and professional jealousies can be kept in abeyance sufficiently for the purpose. Can it be that in the latter years of the nineteenth century these are impossible conditions? On the contrary, is it not true that, in all matters pertaining to sanitation and medical practice, whatever is scientifically shown to be necessary can be made practically feasible. From a commercial point of view there need be no hesitation, and certainly the profession must at all times hold itself in readiness to assume any attitude or to make any advance that science may demonstrate to be at once both logical and necessary, as well as ultimately inevitable.

It is not the design of this paper to suggest details, but the plan itself, in outline, palpably involves the location and organization of a considerable number of separate yet associate institutions at the most desirable sites to be found throughout the country; the selection of a central medical board, and of a local auxiliary board in every city and town of any size, these boards to be composed of progressive and representative physicians, who would enter into the spirit of the movement with some degree of professional enthusiasm, and who in their respective localities would act as referees, advisors, and examiners for the system. Such a body of medical experts as could be selected to compose these boards would unquestionably command the respect and unhesitant confidence of the entire community. Their examinations and advice, unbiassed by narrow prejudices or by personal interests and preferences, would be universally accepted, and would serve to prevent the sending of applicants to climates and locations manifestly unsuited to their individual conditions. This latter item of itself would be a great advance over the present practice. In the composition of these boards, if only men of broad culture, liberal

views and genuine professional honor be allowed to acquire influence in connection with the management, and if medico-political cliques can be rigidly avoided, there need be no difficulty in securing the requisite degree of professional harmony.

It can hardly be doubted that such a system of sanatoria, intelligently organized on thorough business principles and directed by good and earnest men—of whom there is no dearth in the profession—would be accorded a patronage unprecedented in the history of medicine, or rather in the history of health-seeking. The country is full of invalids, and doubtless always will be. At present not one in ten of those who ought to be in some well-equipped institution, specially adapted to their conditions, can be persuaded to present himself for treatment, for the very cogent reason that, considering the cost, commensurate results are not sufficiently promising, or because the various and contradictory advice vouchsafed by different authorities is so bewildering that he comes to lose faith in all climates, localities and institutions. On the other hand, under the proposed system, each locality would have its board of three, five or more skilled physicians, before whom applicants could go with every assurance that in giving advice their cases would be fully investigated and their future interests carefully conserved.

Again, under such a systematic and eminently rational arrangement many of those absolutely hopeless cases, now either selfishly or injudiciously sent away from home and friends only to quickly decline and die, would be frankly and considerately advised to spare themselves the risk, fatigue and expense of a worse than fruitless journey. While this course should unquestionably be universally followed for the reason that it is infinitely more humane to all such patients, it would also prove far better for the reputations of sanatory institutions. On the other hand, hundreds of cases unquestionably amenable to systematic treatment at a well-regulated sanatorium, but which, for reasons indicated, do not now seek these institutions, under such advice as has been outlined would eagerly and early apply for care and treatment. Thus, while the patronage would be constantly and substantially increased, its general character would at the same time be materially improved by the exclusion of patients in the last or hopeless stages, as also those afflicted with incurable diseases, cases whose presence in any, except it be a special institution, results in no good to them, while it acts as a serious depressant and menace to others.

Theoretically the foregoing suggestions seem plausible. Can they be made to materialize?

It has passed into a proverb that doctors are neither capitalists nor good business managers; but, as with all such sweeping rules, there must be plenty of exceptions. Capitalists are not presumed to appreciate all the sanitary and scientific arguments adduced; they demand commercial proofs. But if barely one per cent. of the active practitioners of the United States would combine, each contributing his influence and a very modest amount of spare capital, such a promising nucleus would be secured that plenty of capital would soon be found seeking the investment.

If the proposition seems chimerical on account of its implied financial magnitude, what shall we say of the numerous quack medicine schemes that are so readily floated in the stock market, each on the basis of several millions of capital stock?

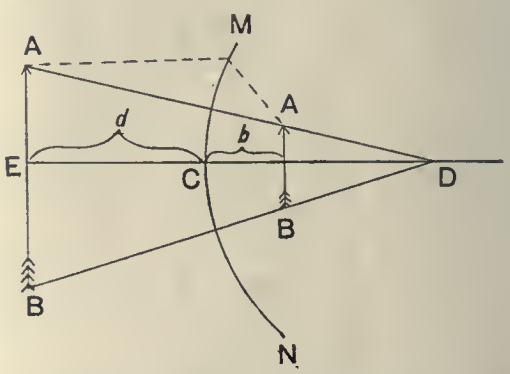
Gentlemen of the profession, are you ready for the question?

A CRITICAL STUDY OF THE MAIN DEFECTS OF JAVAL'S OPHTHALMOMETER.

BY CARL WEILAND, M.D.,
ASSISTANT IN THE EYE DEPARTMENT OF JEFFERSON MEDICAL COLLEGE HOSPITAL, OF PHILADELPHIA.

JAVAL'S ophthalmometer was first brought before the profession about a decade ago with the claim that it enabled the ophthalmologist to determine corneal astigmatism objectively to within a quarter of a diopter. This claim seems now to be conceded by many members of the profession; but I think it will be clear after the following exposition that such a claim is *untenable*, especially according to Javal's own mathematic method, and that it is only by accident (*sit venia verbo!*) that this claim has been partially substantiated in practice.

FIG. 1.



To understand this seemingly paradoxic statement I must ask my readers to glance at a few mathematic formulæ. First, however, let us recall the method of finding the radius of curvature of a convex mirror, such as the anterior part of the cornea is.

If A B (Fig. 1) be the object, at a right angle to the optic axis E D; if M N be the surface of the convex mirror, the center of which lies at D, and

if E C $= d$ and the distance of the image A′ B′ from M N $= b$, then we have

$$(I)\ \frac{1}{d} - \frac{1}{b} = -\frac{2}{r}\ (\text{if } r = \text{C D}),$$

and further,

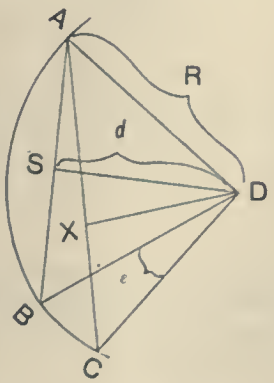
$$(II)\ \frac{\text{A B}}{\text{A}'\text{B}'} = \frac{d+r}{r-b} = \frac{\text{Size of object}}{\text{Size of image}} = \frac{\text{O}}{\text{I}}.$$

If we express r in equation (II) in terms of d and b of (I), we get $\frac{\text{O}}{\text{I}} = \frac{d}{b}$, or expressing here b in terms of d and r by equation (I) we have $\frac{\text{O}}{\text{I}} = \frac{2d+r}{r}$ (III).

Now, here lies the *first inaccuracy of Javal*, for he makes $\frac{\text{O}}{\text{I}} = \frac{2d}{r}$, which is right only if the object lies so far from the mirror that its image falls at the focus of the mirror, which is at $\frac{r}{2}$. Really, Helmholtz did use the formula $\frac{\text{O}}{\text{I}} = \frac{2\,d}{r}$ because he placed his object at 2000 mm. from the cornea, while Javal makes $d =$ only 280 mm. To prove the inaccuracy we have only to remember that Javal's instrument is so constructed that the image, I, always $= 3$ mm. as soon as the two reflectors have been moved so that their two inner images touch. Therefore, $\frac{\text{O}}{\text{I}} = \frac{2\,d}{r}$ becomes $\frac{\text{O}}{3} = \frac{560}{7.8}$, as r, the average radius of curvature of the cornea, equals 7.8 mm. Then O $= 216$, while by using $\frac{\text{O}}{\text{I}} = \frac{2\,d+r}{r}$ we get O $=$ 219 mm., which is a difference of about 1 5 per cent.

Another inaccuracy of Javal's instrument arises from the fact that his reflectors slide on an arc, for

FIG. 2.



this sliding changes d continually, as will be easily seen by the following diagram (Fig. 2). Here A B C is the arc on which the reflectors are moved. Suppose, now, that the one slider has to be moved from B to C to get contact of their images, then d will change also. It will become R cos $\left(\alpha + \frac{\varepsilon}{2}\right)$, if R $=$ A D, or the distance of the arc from the cornea, and α the primary angle A D S, and ε the angle between B D and C D. Javal, however, makes $d =$ R cos α a constant quantity all through his calculation. One may object to this criticism as being very trivial, and, indeed, numerically it does not amount to much; but it must be mentioned here, because it can be so easily remedied that it is astonishing that it escaped Javal's mind.

The *main error of Javal*, however, lies in the following: In his own description of his instrument he states that f, the focal distance of the cornea, $= \frac{r}{n-1}$, if r is the radius of the cornea and n the index of refraction of the cornea and aqueous humor. Now, as we want to find the refractive power of the cornea for rays coming from the outer world, it is undoubtedly true that f can only $= \frac{r\,n}{n-1}$, for this alone tells us how far back from the anterior surface of the cornea parallel rays from distant objects would meet. Or, if we express it in diopters, then we must say, the refractive power of the cornea $\text{D} = \frac{1000}{f} = \frac{1000\,(n-1)}{r\,n}$. *This* is the right formula, and *not Javal's*, whose expression for D is $\text{D} = \frac{1000\,(n-1)}{r}$. The following table will illustrate the difference:

43.1 D of Javal ought to be	32.3 D for $r =$	7.8 mm.
40.5 D " " "	30.3 D for $r =$	8.3 mm.
37.1 D " " "	27.7 D for $r =$	8.8 mm.
30 D " " "	22 5 D for $r =$	11.2 mm., etc.

Now, it may be said that the question is not so much as to the absolute refractive power of the cornea, but the difference between those powers in the different meridians, or the amount of astigmatism. But it must be replied that the amount of astigmatism is affected also, as is shown by the following examples:

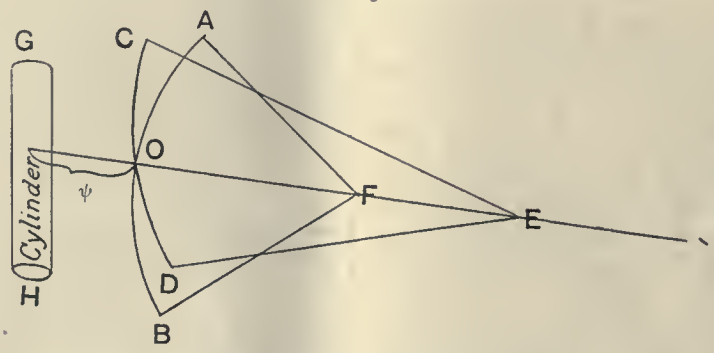
6 D astig. of Javal only	$= 4.6$ D	astig. of cornea.
3.4 D " " "	$= 2.6$ D	" "
2.6 D " " "	$= 2$ D	" "
1 D " " "	$= 0\,74$ D	" "

In short, all the values of Javal for the amount of refractive power of the cornea and the amount of corneal astigmatism are n times too large, if $n =$ index of refraction $= 1.337$.

"But how is that?" the impatient reader will ask. "Does not clinical experience show that Javal's instrument does often give very good results?" I answer, Yes, often, but not always; and must add that this result is not obtained by the right calculation, but results very strangely from

accidental causes, as follows: It is well known that the value of a lens changes with regard to its optic effect on the eye according to the position the lens occupies. Now, if Javal were right in his calculation, so that his instrument showed the real astigmatism of the cornea, then quite a different glass would have to be used at 15 mm. from the cornea, the anterior focal point of the eye, where our lenses ought to be placed. Still we use Javal's numbers even at that distance from the eye, which shows plainly that his calculations for the integral corneal astigmatism must be wrong. To make this more clear let us look at the following figure (Fig. 3): Let A B

FIG. 3.



be the vertical and C D the horizontal meridians of the cornea, which are of differing curvatures, so that F is the focus of the rays through the vertical and E the focus of those through the horizontal meridian. If the refractive power of the cornea in the horizontal meridian = D diopters, and that of the vertical = D′ diopters, if D′ is supposed to be greater than D, what lens have we to place at the anterior focal point of the eye at the distance of ϕ mm. from the cornea, or, more correctly, from the first principal point of the eye, in order to make the combined refractive power of a cylindrical lens and the cornea in the horizontal meridian equal to that same power in the vertical meridian? To simplify the problem, however, let us put the cylinder, not at ϕ, but at the *anterior* focal point of the *cornea*, which is $= \frac{r}{n-1} = \frac{7.8}{0.437} = 23$ mm., while ϕ would be about 15 mm. from the cornea. Now, it is well known that if a lens is placed at the anterior focal point of an optic system, the second principal point, and with it the second principal focus, of the combined system is obtained by moving these points of the given system in the same direction through the same definite extent. In our example the second principal point lies, together with the first principal point, at the apex of the cornea, and it is moved through $\frac{\psi\psi'}{f}$ mm. away from the cornea, if ψ and ψ' are the anterior and posterior foci of the cornea and f the focal distance of lens or cylinder. As we want the rays through C D also to come to a focus at F, we have to choose our lens so that

$$F E = \frac{\psi\psi'}{f} = \frac{\psi \times 1000}{fD}, \text{ because } D = \frac{1000}{\psi'}.$$

This we may write

$F E = \frac{\psi D_L}{D}$, if we mean by $D_L = \frac{1000}{f}$, the refractive power of the cylinder in that meridian. Further, it is clear that F E, the focal interval, $= \frac{1000}{D} - \frac{1000}{D'}$, as $O E = \frac{1000}{D}$ and $O F = \frac{1000}{D'}$. Therefore, we have now $\frac{1000}{D} - \frac{1000}{D'} = \frac{\psi D_L}{D} = \frac{1000 (D' - D)}{D D'}$

And as $\psi = \frac{r}{n-1}$ and $D = \frac{1000 (n-1)}{rn}$, we can write for $\frac{\psi}{D}$ the value $\frac{1000}{D^2 n}$, so that we have

$$\frac{1000 (D' - D)}{D D'} = \frac{1000 D_L}{n D^2}, \text{ or } \frac{D' - D}{D'} = \frac{D_L}{n D}.$$

Therefore, $D_L = \frac{n D (D' - D)}{D'}$, if $D' - D =$ the amount of real corneal astigmatism $= d$. The value of our lens, therefore, which, at the anterior focal point of the cornea = 23 mm., corrects the corneal astigmatism, is $D_L = \frac{n D}{D'} d = \frac{n (D' - d)}{D'} d$. This we may write $D_L = \frac{n D}{n D'} n d$; and as we know from former considerations that the real values of astigmatism and corneal diopters have to be multiplied by n to get those of Javal, and if the respective values of Javal are called Δ, Δ', and δ, we have $D_L = \frac{\Delta}{\Delta'} \delta = \frac{\Delta' - \delta}{\Delta'} \delta = \delta \frac{\Delta}{\Delta + \delta}$. Now, usually $\frac{\Delta}{\Delta + \delta}$ is not much different from 1, and so we get approximately $D_L = \delta$, if $\delta =$ Javal's astigmatism. Suppose, for example, that there was a real corneal astigmatism of 3 D, then Javal's instrument would

indicate an astigmatism of 4 Δ, while the real correction at 23 mm. would be a cylinder of 3.6 D. So 1 real D would be 1.337 of Javal = 1.19 at 23 mm. if the meridian of lowest curvature was 37.1 Δ. These values would change a little if the lens were placed at 15 mm. away from the cornea—*e. g.*, 3.6 D at 23 mm. would be 3.7 D at 15 mm. In the higher forms of astigmatism, however, the difference is very considerable; for, suppose that Javal's instrument showed 8 Δ astigmatism, then this would equal 6.5 D at 23 mm. from the eye and 6.8 D at 15 mm. away from the eye, so that between Javal's glass and the true cylinder there would be a difference of about 1.25 D, certainly a very considerable amount. In the same way, Javal's 6 would be equal to a 5 cylinder.

Another inaccuracy must be mentioned still, with reference to the graded reflector, where each step is supposed to indicate one diopter. To get the size of those steps Javal uses the formula $\Delta = \frac{1000\,(n-1)\,O}{2\,d\,I}$ where d is the distance of the object O from the cornea, while the right formula would be

$$D = \frac{1000\,(n-1)\,(O-I)}{2\,d\,n\,I}.$$

Now, Javal makes d *about* 281 mm. in his latest model (it changes continually, as already proved), and $I = 3$ mm.; and as $n = 1.337$ we get

$$\Delta = \frac{337 \times O}{281 \times 6} \text{ and } 1 = \frac{337 \times O}{281 \times 6} = \frac{O}{5},$$

from which it follows that $O = 5$ mm. for each diopter, while from the true formula

$$D = \frac{1000\,(n-1)\,(O-I)}{2\,d\,n\,I}$$

it follows that the object O ought to increase 6.7 mm. for each diopter. But while Javal is right in making the steps of his reflector = 5 mm. each for *his own* diopters, he is wrong in making those reflectors curved, because each step has then less value than 5 mm. as measured in the line of union of the two reflectors.

So far, all the objections raised have nothing to do with the principle of the instrument, but only with the special form given to it by Javal. For it must not be forgotten that the instrument is almost the same as that described by Rochon in the *Journal de Phys.*, vol. liii, in 1801, and that it has a good place in science under the name of Rochon's micrometer. Javal only gave the bi-refracting prism a definite place in the telescope and then made the calculation for the refractive power of the cornea, adding an arc and two reflectors. Now, the calculation and the arc, as well as the two reflectors, are not quite correct, but the error might be easily rectified, and so a more perfect ophthalmometer on Rochon's principle be constructed. But it seems to me that there is a serious defect in the very principle of the instrument, because the bi-refracting quartz-prism is not achromatic, so that the margins of the images are not sharply defined, which makes it impossible to get the accurate contact so necessary for an accurate result.

THE BLENDED TOCCI BROTHERS, OF LOCANA, ITALY.[1]

BY ROBERT P. HARRIS, M.D.,
OF PHILADELPHIA.

[Dr. Harris brought to the notice of the College an enlarged photograph of this remarkable monstrosity, which had been prepared for the Mütter Museum at the desire of its curator, and made the following remarks.]

WE have here a nude representation of what we must regard as the most remarkable duplex monstrosity that the world has seen since the death, three hundred and seventy-four years ago, of their Scotch analogue, which had reached the age of twenty-eight years. This peculiar type of blended twins appears, on an average, twice in a century, as there have been about a dozen in the last six hundred years, and but two in the current century. The most remarkable feature about the Locana twins is that they are living and in good health at the age of fourteen and a half years, and bid fair to reach mature age, because of the perfection and independence of their thoracic and abdominal viscera. In the last six hundred years but two monstrosities of the same type have lived out their first year; and this early mortality we must attribute to a want of internal anatomic symmetry, and particularly to an abnormal construction of the heart and distribution of the bloodvessels in one twin. It is doubtful if united twins are ever equals in mental and physical vigor, and the Tocci Brothers are as nearly alike in health and strength as has been the case in the subjects that have lived the longest.

The photograph before us represents the boys in a standing position, but it will be seen at once that they are mainly sustained in it by the use of their arms, and that this is more markedly the case with the left twin, whose shoulder is forced upward, because of the weak support given by his club-foot and imperfectly developed leg.

These twins were born in Piedmontese Italy, on October 4, 1877, after a labor of eight hours, under a midwife, the head of the right boy, Giovanni, coming first; and he appears to have held that relative position, in a mental sense, ever since. Giacomo's head soon followed, and then came the double thorax, a single abdomen, one pair of legs, and a single placenta. Nothing was said about the cord, except that there was but one; but it was no doubt composed of six vessels—four arteries and two

[1] Read before the College of Physicians of Philadelphia, May 4, 1892.

veins. The twins weighed eight and three-quarters pounds when a month old, and probably a pound less at birth. When three years old, as shown by a photograph, they had narrow shoulders, a corpulent abdomen, and, for their age, large testicles. Giovanni had a long face and a girl-like appearance, but his head-circumference has always been a little the larger of the two.

These xiphodidymi belong to the class that is distinguished by having two heads, four arms, and only two legs. In general outline they resemble, when their legs are together, a letter Y—the heads, shoulders, and chests down to the sixth ribs making the V, and the abdomen and legs the I, or stem. Their present weight is ninety-five pounds, which is about that of a healthy, robust boy of their age. Their arms having much more exercise than their legs, are larger, in proportion to their age, than the latter; and the glutei muscles of Giacomo are badly developed, because of his talipes equino-varus, and consequent inability to develop them by exercise. Single boys of fourteen, as a rule, have much better developed legs than arms, which led to the expression in war times: "Better fitted for running away than handling a musket." But the Tocci boys are the reverse of this in strength.

If we had a back view of the monstrosity, it would show their two inner arms crossing each other over to their outer shoulders, in the position in which they usually hold them; two converging spinal sulci extending down to two sacra; two outer nates as in a single subject, and two little rudimentary nates, with a cleft between them, located over the intrasacral symphysis. They have no rudimentary nodule to represent an attempt at the formation of a third leg, as has been found in some analogues.

As they look at you, the two boys are quite different in facial contour, and Giovanni is generally credited with having the better mind; but their faces in profile bear a closer resemblance. They have fair skins, and at times a rosy color, and thick, brown hair. Their bodies are short, and they are below the medium height for their years. Their acial expression is not a happy one, when in repose, and reminded me of what I have noticed in boys having deformed feet—a shame-faced look.

In measure of health the twins compare well with normal children of their own sex, having had but little sickness since birth, and not having lost a day therefrom since they commenced to exhibit themselves in the United States, six months ago.

Giovanni is the stronger and more erect of the two, has the better ear for music, learns a foreign language the more readily, and is generally the more intelligent. He has a natural talent for drawing, and is devoted to making pictures of our domestic animals, such as the horse, cow, etc., and of some of the savage quadrupeds, as of the lion and tiger. Giacomo is the critic in art, although drawing but little, and his taste is for caricatures. The brothers converse a great deal together. They are both right-handed, although one might have supposed that Giacomo would have naturally preferred his free arm, the left.

The boys have each two lungs, the outer being the larger, and are forced to breathe largely by their diaphragms. They have separate and distinct hearts, located in the left chest-cavity respectively, and these hearts are believed to be normal in structure. Giovanni feels his heart beating on the left side—and if either boy had an abnormal cardiac structure, he should be the one, yet his color and health indicate the contrary. The cardiac beats are not synchronous, and one heart generally pulsates a little more quickly than the other.

They have two stomachs, and that of Giovanni is said to be reversed, the greater curvature being to the right, as was the case in Rita, of the Sassari girls of 1829. I was not permitted to verify this, because of the opposition of the father. These two stomachs are as independent functionally as if they occupied two different abdomens. Recently, when travelling by railroad, one of the boys became very pale, and directly vomited the contents of his stomach,[1] while the other was so entirely free from nausea that he laughed at his brother for his mishap. One brother may wake up hungry, drink a cup of coffee, and eat something, while the other remains asleep. The two stomachs do not appear to be influenced in the least by being in contact, but only by their respec tive pneumogastric nerves.

There are evidently two sets of intestines—large and small. One boy can have a desire to defecate when the other has not; and this is particularly the case when one has diarrhea, in which event only he has a discharge, while the other is passive. There must therefore be two colons, as were found on autopsy in the Padua boys of 1691. They have probably a common rectum, as had also the Padua analogue; but it is possible that this part of the bowel may be bifid, which would be an interesting feature to determine by touch or speculum. The twins, from habit and convenience, defecate almost always at the same time.

They have two bladders and one urethra, as had also the Padua boys, although they usually urinate together. As their tastes for food and desire for drink are not the same, one boy may be awakened from his sleep in the morning by a distended bladder and empty it without waking up the other, in whom the kidneys have been less active.

My catechetic examinations made last month

[1] This was repeated by Giacomo in public on April 23, 1892, at the Dime Museum, Philadelphia.

confirm the opinions respecting the anatomy of the twins that were formed after auscultation, percussion, and a knowledge of their habits, by Drs. Fubini and Mosso, of Turin, in their second month, and by Drs. Colrat and Rebatel, of Lyons, in their thirteenth. The conjectural belief that they might have two colons has been changed into one of knowledge, as shown by their independence in defecation. In the event of an autopsy, these colons will no doubt be found of small caliber, and quite abnormal as to length and direction. We are warranted in this belief by discoveries that have already been made in the examination of dead analogues. Even the single colon of a double monster is quite abnormal.

The boys are quite differently affected by changes of temperature. Giovanni requires less underwear than his brother, and will perspire freely on a hot day, while Giacomo has a dry skin. Either brother may be seized with an attack of coryza, as the effect of a direct wind-draught, when the other entirely escapes. They sleep upon the back—or, more correctly, each is in a dorso-lateral position, and places the side or back of his head upon the pillow. They usually sleep eight or nine hours continuously. For a change of position they sometimes turn over upon their abdomen for a short time, but never sleep in this form of decubitus.

A prick with a pin in the median line of union is felt by both brothers, but the sensation is lost to one twin in passing to either side. The penis is said to have a sensation common to each, and the scrotum has a partial one beyond the median line. It is claimed that one twin feels a little when his brother's testicle is touched, which I believe to be an error, the sense being in the skin only, as the testicles are supplied with nerves through the inguinal canal. The penis and testicles are in an undeveloped state, being small for their age. The penis becomes erect, but the boys have no knowledge of its sexual function.

The two legs are entirely independent, and each belongs to, and is controlled by, the boy whose head is on the same side. One boy does not feel a touch upon the other boy's leg, and has no power, by his will, to give it the least motion. It is possible that the twins might balance themselves so as to stand, as their Scotch analogue is said to have done, if the leg and foot of Giacomo were as well formed as those of Giovanni, and had the same degree of strength that the latter appear to have.

Whether the boys have two separate livers, or a double one with two gall-bladders, has not yet been ascertained, for want of permission to make the required examination. Having two bladders, they may have two pairs of vesiculæ seminales, but are more likely to have one to each bladder, with one vas deferens and one ejaculatory duct, as this would be in correspondence with the existence of one testicle to the owner of each bladder, and one urethra for the exit of the ducts. I find no reference to the seminal vesicles in any reports of autopsies made in male analogues.

With regard to the other viscera, we can only form an inferential opinion, as follows: The spleens are small, and located right and left to correspond with the positions of the stomachs. The pancreases have their heads facing each other, to correspond with the curve of each duodenum. The kidneys are in two pairs, the outer being large and the inner being small, or, perhaps, rudimentary. It is rare to find no trace of the two inner kidneys when the spinal columns are well separated so as to give space for them.

I see no reason why these Tocci boys may not live a number of years yet. Giovanni is the stronger, mentally and physically, but the difference is not marked, and no special element of weakness likely to shorten life appears to have been discovered in Giacomo. They have both learned a certain measure of French and German, and can both sing, Giovanni having the higher-pitched voice. One of the Scotch twins already mentioned as having reached the age of twenty-eight is recorded as having been quite stupid when compared to his brother. We have no such difference to record here.

THE VALUE OF MILK-LABORATORIES FOR THE ADVANCEMENT OF OUR KNOWLEDGE OF ARTIFICIAL FEEDING.[1]

BY T. M. ROTCH, M.D.,
OF BOSTON,
ASSISTANT PROFESSOR OF DISEASES OF CHILDREN, HARVARD UNIVERSITY; VISITING PHYSICIAN TO THE BOSTON CITY HOSPITAL, TO THE CHILDREN'S HOSPITAL, AND TO THE INFANTS' HOSPITAL.

Two important factors are demanded by physicians of the present day in solving the problem of rational medicine: First, a means of saving time; second, exact methods of work.

I have long felt that the artificial feeding of infants should be reduced to a more exact system, and that in this way an endeavor should be made to rescue this important branch of pediatrics from the pretensions of proprietary foods and the hands of ignorant nurses. With this purpose in view I have established a laboratory in which the materials used are clean, sterile, and exact in their percentages, and are combined in any proportion that the physician may wish to prescribe. Laboratories of this kind should be established everywhere, and physicians should write prescriptions for their infant patient's food and put them in the hands of the milk-modifier in his laboratory, just as they

[1] Abstract of a paper read before the American Pediatric Society, May 4, 1892.

write for combinations of drugs in disease, and entrust them to the pharmacist in his drug-shop. As the result of clinical experience in infant-feeding I have reached the conclusion that slight changes in the percentages of the three elements of milk, of which we have most accurate knowledge, namely the fat, sugar, and albuminoids, have an important bearing upon the management of the digestion and nutrition of infants.

In analyses of milk from seven women the fat, sugar, and albuminoids varied to a marked degree, and yet the infants all digested well and throve on their individual percentages, while what agreed with one produced serious symptoms in another. It seems, therefore, that so far as milk is counted upon as a food, it should be understood to be a general name of the food for the infant, just as dinner is a general name of food for the adult.

This general dinner (milk) of the infant should also be modified in its various parts to suit the digestion of the individual infant.

Perhaps it would be of interest to know what materials were needed, and what processes were gone through with in carrying out the prescription of the physician.

A laboratory such as that described has already been established in Boston, and is in successful operation, a number of physicians having found it to be an indispensable adjunct to their daily practice.

An important matter is the careful supervision of herds of cows especially selected as to breed and systematically fed, so that the analysis of their milk should be of an almost unvarying percentage. The morning's milk of these cows, milked into glass and kept scrupulously clean, is rapidly cooled and in a few hours delivered at the laboratory. The atmosphere of the laboratory is kept pure and fresh by means of a large fan that keeps up a constant outward current of air. The laboratory itself is lined with white tiles, and contains a separator by means of which a stable 16 per cent. cream can be quickly obtained from the milk. There is also a large sterilizer into which not only steam can be introduced, but in which the milk can be exposed to high or low temperatures, at the will of the modifier.

Having once obtained a pure, clean skimmed milk and cream of a stable percentage, it is merely a matter of mathematic calculation to combine these fluids in such proportions as to produce a mixture in the percentages of fats and albuminoids prescribed by the physician.

The sugar percentage is obtained in like manner by using a carefully prepared 20 per cent. solution of milk sugar and distilled water.

Diagrams were made to show the prescriptions written by the physicians in fat, sugar, and albuminoid percentages, the same prescriptions translated into drams and ounces by the milk-modifier, and the figures returned by the chemist to whom the modified milk was sent to test the accuracy of the modifier's calculations.

I have had a large number of test analyses made, so that there is no longer a doubt but that fairly exact combinations can be made in this way.

As the chemistry of the mineral matter in woman's milk is so little known, it is better to ignore that element for the present. Three figures only need be remembered, corresponding to the percentages of fat, sugar, and albuminoids in average human milk—namely, 4, 7, and 1.50.

Starting with these figures the physician can then easily change one or more of them, either to increase or decrease, according to the need of the especial infant.

As objection has been made to sterilizing at 212° F., this could just as well be done at the safer and lower temperature of 167° F. in the laboratory sterilizer.

The Treatment of Fecal Impaction by Means of Galvanism.—SOUTAKIS (*Gaz. Méd. d'Orient*, 1892, p. 20) reports the case of a woman, sixty-three years old, in whom constipation had existed for five days, with symptoms of fecal impaction. Ordinary remedies had been employed, but without avail. Repeated intra-rectal applications of galvanism, by means of a suitable sound, were followed by active intestinal peristalsis, and the evacuation of a large quantity of scybalous fecal matter.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

THE "MEDICAL MIRROR" ON NOSTRUMS.

AN esteemed contemporary applies the following elegant epithets to those that believe the medical profession should not become a mere appendage to the trade of the drug-manufacturer, and that selling nostrums is not quite the same as the healing and prophylaxis of disease: "Two-for-a-nickle," "small-bore," "small-bores half-and-half," "shoddy pretenders of the medical profession," "bombastic boasters and pretenders," "hump-backed members," etc. We have no doubt the superior perception of the readers of our urbane co-laborer will enable them to understand how "pharisaism" may be "ethical," and also to distinguish clearly the subtle difference, hidden from us, between "small-bores," and "small-bores half-and-half."

But such evidences as these of "local color" are introductory to the charmingly naïve explanation that the opposition of the "hump-backed" is solely a question of sour-grapes. The "two-for-a-nickel," our contemporary avers, are disgruntled, because they have no practice or standing "in their own bailiwick," and having no practice, they have not been asked to give their opinion of the "so-called proprietary medicines" made by "the practical, pushing pharmaceutical world," which has "secured good traveling men to present their supplies to the profession, having convinced them [*sic*] favorably through the medium of medical journals and attractive circulars." This is delicious! Barkis was, certainly, never more willin', nor ever more regardless of English grammar.

Somewhere, we have seen an amusing and suggestive toy. It also was a mirror, of convex, cylindrical pattern, placed at an axis of 180°. Looking a little steadily at it, behind one's own ludicrously distorted image, the eye caught another reflection of the figure of a squat Chinese caricature, wagging its head with a satyr's grin. The real china figure above, cunningly reflected in the distortion mirror, would smile and bow continual assent for several minutes, for so small an amount as a penny placed in its huge mouth; but, the larger the coin the more wide-mouthed the cunning grin, the more energetic, subservient, and long-lasting the bows!

* * * * *

How easy it is to ascribe mean motives to those who may oppose our own pet vice. The spoilsman in politics cannot comprehend the high-principled devotion that places public welfare above partisanship, and straightway he raises the cry of "Pharisee!" The spoilsman in medicine, without the faintest glimmer of the pure light that illumines the soul of the true physician, is roused to frenzy by the exposure of his methods, and spits out of the blackness, venom that falls harmlessly wide of its mark. That was shrewd advice of the old lawyer to his son: "When law and justice are both against you, talk around the case and abuse the plaintiff's attorney." The advice has not been wasted on *The Medical Mirror*.

But what can the *Mirror* expect to gain by its adoption of the methods of the pettifogger? The issue to be presented at Detroit to the representatives of American medicine is clear-cut and direct. Not any individual, but the largest County Society and the largest State Society in affiliation with the American Medical Association will, by the unanimous action of well-attended meetings, appear as plaintiffs. The nostrum manufacturers and their journalistic allies cannot well hope to silence by slander two such bodies.

The law is plain. Section 5 of that article of the Code of Ethics which treats of "Duties for the Support of Professional Character," declares it to be "reprehensible for physicians to give certificates attesting the efficacy of patent or secret medicines or in any way to promote the use of them."

Justice is on the same side, "for"—to quote the same section of the same Code of Ethics—"if such nostrum be of real efficacy any concealment regarding it is inconsistent with beneficence and with professional liberality, and if mystery alone give it value and importance, such craft implies either disgraceful ignorance or fraudulent avarice."

Columns of abuse and vituperation cannot obscure these luminous facts. The code is still the unrepealed law of the American Medical Association; and whoever claims good standing in that Association must be prepared to prove his obedience to the law. Most certainly the trustees of *The Journal* should be held to strict accountability in their management of that sacred trust.

If the law is oppressive let the open attempt be made to repeal it. How hopeless such an attempt would be, *The Mirror* and the nostrum-makers well know, or long ere this it would have been made. The law cannot be repealed, for it is founded on a principle that is indeed antiquated but can never become obsolete, on the eternal principle of right. The terse language of the code expresses this beyond the necessity of a single added word.

SOCIETY PROCEEDINGS.

ASSOCIATION OF AMERICAN PHYSICIANS.

Seventh Annual Meeting, held at Washington, D. C., May 24, 25, 26, 1892.

(Continued from page 615.)

SECOND DAY—MAY 25TH.

DR. F. T. MILES, of Baltimore, reported "A Case Presenting the Symptoms of Landry's Paralysis, with Recovery." The condition was thought to be dependent upon a polyneuritis. The clinical picture bore a close resemblance to that of acute ascending paralysis. It was especially noted that the faradic contractility was preserved. The paralysis was of gradual onset, progressively invading the body from below upward. There was an absence of pain, spontaneous or upon pressure. The full text of the paper is to appear in a subsequent number of THE NEWS.

DR. ALEXANDER MCPHEDRAN, of Toronto, reported "A Case Showing the Symptoms of Landry's Paralysis; Recovering." A clerk, twenty-six years old, with the exception of malarial fever fifteen years ago had always been healthy. His present illness began December 2, 1891. For three or four days before this, he had noticed uncomfortable sensations in the feet, which he supposed to be due to his boots. On the evening of December 2d, after stooping to close a safe, he found it difficult to rise again to the erect position. On the following morning, on rising, he found his legs to be very weak; he was able to dress and walk down stairs, but had immediately to lie down on a sofa. While dressing, he first found trouble in the use of his hands, and then some muscular pains in the forearms and shoulders. The electric reactions were normal. On December 4th, the paralysis of all the extremities was complete. The muscles of the trunk and neck were also involved, so that the head could scarcely be raised from the pillow. Speech, swallowing, and breathing were unaffected; sensation was normal; the bladder and the rectum acted normally; the knee-jerk was absent. On December 10th, the speech became somewhat thick. No other change was noted in the symptoms. On December 12th, swallowing was slightly affected, so that there was considerable difficulty in taking soft food. This difficulty soon improved and disappeared in a few days. On December 13th, some pain was felt in the lumbar region; this was relieved by heat, but recurred frequently for a week. On December 20th, the reflexes were still absent; there was no wasting; no tendency to bedsores; the man was able to move his hands and forearms slightly. On January 1st, motility had to a slight degree returned in all of the extremities, being most advanced in the upper. The patient was able to maintain the sitting posture in an arm-chair and to hold the head erect for a few minutes without support. The knee-jerk was quite distinct on the right and slightly developed on the left. On February 3d, the man was able to walk a few steps unsupported; he used his hands freely, though the muscular power was still deficient. He continued to improve, and was soon able to walk freely; the knee-jerk became somewhat exaggerated; there was no ankle-clonus. Sitting with his elbows resting on the arms of his chair and fingers extended, there was marked tremor of the forearms and hands while the position was maintained. On April 20th, the man appeared vigorous and walked well, but if he allowed the knees to bend much they would give way under him; the knee-jerk was increased. The electric reactions continued normal throughout. The spleen could not be felt at any time, although the area of dulness was slightly increased.

In the discussion, DR. CARY, of Buffalo, reported a case in which there was paralysis of the lower extremities and of the sphincters and finally paralysis of the upper extremities, with interference with the respiration, so that suffocation was feared. The pulse rose to 130 per minute. The power of deglutition and of phonation was lost. The symptoms lasted for two or three days, when improvement set in and the condition gradually subsided in the way in which it began. At the expiration of a year the man was about well. The case was considered one of Landry's paralysis by several physicians by whom it was seen.

DR. THOMSON expressed the view that the involvement of the sphincters would seem to exclude the case as one of acute ascending paralysis.

DR. M. ALLEN STARR, of New York, presented a paper entitled "Local Anesthesia as a Guide in the Diagnosis of Lesions of the Lower Spinal Cord." He maintained that in testing sensibility it is not enough to ask a patient whether he feels the touch of the cotton-wool, or the tip of the finger, or the warm or cold test-tube, or the prick of the needle, or the sting of a faradic brush; nor is it sufficient to touch two parts successively, and demand that he compare a sensation with a memory. He should always be tested upon two surfaces simulta-

neously, and asked if any difference is felt between the sensations.

In spinal affections the face is a convenient surface with which to make comparisons; and in the diseases of the lower region of the cord, the arms and trunk may be used as a standard of normal feeling.

Dr. Starr reported twelve cases that he had collected, including six that he had himself observed, in which lesions of the spinal cord were attended with definite areas of anesthesia. From a study of these he endeavored to show that a limited area of anesthesia is produced by a limited lesion in the spinal cord; that as the lesion ascends the cord from its lowest limit, the area of anesthesia extends in a definite manner upon the surface of the body; and that the situation and shape of the area of anesthesia is a positive indication of the level of the lesion in the spinal cord. It appears that, as the centers of control of the bladder and rectum are uniformly affected together, they must be adjacent to one another. The control of the sphincters is lost when the lesion involves the lower three sacral segments, and the centers probably lie in the lower two segments of the cord. Seven concentric zones of anesthesia were determined in conjunction with lesions of the lower part of the spinal cord.

The *first zone* is oval-shaped, small in extent, and includes the perineum, the posterior part of the scrotum in males, the vagina in females. It also includes the mucous membrane of the rectum.

The *second zone* is heart-shaped, with the apex above, and includes the entire scrotum and posterior surface of the penis and mucous membrane of the urethra in males—the entire genitals of the female, except the outer surface of the labia majora and the mons veneris.

The *third zone* involves a greater surface of the buttocks and extends down the back of the thighs over a triangular area, the apex of which is directed downward. This has been named the "saddle-shaped area," approximately coinciding with the surface of the seat in contact with the saddle when riding. A zone of anesthesia of this shape is due to a lesion involving the fifth, fourth, and third sacral segments.

The *fourth zone* is of a similar shape to the third, but more extensive, a greater surface on the back of the thighs being involved; and the anesthesia extends in a band almost as low as the popliteal space. As the smaller zone is due to a lesion at the third sacral segment, and the next larger zone is due to a lesion in the fifth lumbar segment, it is allowable to conclude that this region corresponds with the second and first sacral segments.

The *fifth zone* of anesthesia includes the first four zones and extends down the back of the thigh through the popliteal space in a band, and then descends on the outer surface of the leg to the foot. In some cases it ends at the ankle, in others it involves the entire side of the foot, dorsum, and sole, and three and a half toes. When a lesion extends from the sacral into the lumbar cord the anesthesia extends from the thigh down the outer side of the leg. This area then corresponds to the fifth lumbar segment of the cord.

The *sixth zone* of anesthesia is produced by a lesion of the third lumbar segment; the entire back of the thighs and legs is anesthetic and the front of the thighs is also anesthetic, except over a funnel-shaped zone that extends from above downward, the narrow tube of the funnel reaching along the shin even to the foot. This zone will probably later be separated into two separate parts corresponding to lesions of the fourth and third lumbar segments.

The *last* and *largest zone* of anesthesia is produced by a lesion of the four lower lumbar segments—that is, by destruction of all but the first lumbar segment of the cord. The line of anesthesia is much lower in front than behind, and follows the line of Poupart's ligament. It is only when the first lumbar segment of the cord is invaded that the abdominal wall becomes anesthetic.

From this level upward the zone of anesthesia extends around the body in a girdle, and there is no difficulty in locating the level of the lesion in the dorsal cord.

In all of these lesions and areas of anesthesia, the *anus, the perineum, and the genitals are included in the insensitive region.*

It thus becomes evident that a careful study of disturbances of sensation is a valuable aid in the diagnosis of the situation of lesions in the spinal cord and cauda equina. It is, however, to be remembered that anesthesia is but one of a series of symptoms entering into that diagnosis, and that the condition of the reflexes and the power, tone and electric reactions of the muscles are not to be neglected in the examination of any case. It is only when *all* of the signs of a local lesion coincide that the diagnosis is an absolute one.

DR. MORRIS J. LEWIS presented a paper entitled "A Study of the Seasonal Relations of Chorea and Rheumatism for a Period of Fifteen Years—1876 to 1890, inclusive." The conclusions arrived at were based upon the months of onset of 1383 separate attacks of chorea observed in Philadelphia and in Boston; and of 673 separate attacks of acute articular rheumatism observed in Philadelphia. A distinct seasonal relationship was found to exist between chorea and rheumatism. There is a marked resemblance in form between the chorea and rheumatism tracings and the tracing representing the total amount of sickness present in the community per month. This monthly variation in amount of sickness is probably not a cause of the fluctuation in the chorea and rheumatism tracings, but is itself probably due to the same influence. While over-study assuredly plays a most important rôle in predisposing children to chorea, the months of greatest study, and therefore presumably of the greatest depression of bodily vigor, do not with any regularity coincide with, or even precede, the months of greatest frequency of this disease. It is more than probable that "weather" is one of the most important predisposing causes of both chorea and rheumatism, although precisely which meteorologic factor is the baneful one does not clearly appear. No one element of "weather" explains fully the fluctuations of these tracings of chorea, although in the barometer and storm statistics the relationship appears to be closer than to any other etiologic factor or factors that have, as yet, been advanced. Either this apparently close relationship must be acknowledged to have an important place in the etiology of these diseases, or else the resemblance must be considered purely accidental—a conclusion that, from a study of the tables prepared, seems most unlikely.

DR. STARR stated that from a study of 356 cases at

the Vanderbilt Clinic during the past four years, he was able to confirm the general conclusions made from the study of Dr. Lewis. He does not think overstudy a prominent cause of chorea. Sixty-five cases were ascribed to fright. In only 18 per cent. was there a history of rheumatism. It is possible that chorea is more common in the spring because disturbances of nutrition culminate in the spring.

DR. HENRY spoke of other than articular manifestations of rheumatism, and stated that many cases in which valvular lesions of the heart exist might be considered rheumatic. Tonsillitis and certain skin-eruptions are also observed in connection with rheumatism. The relation of chorea and rheumatism may be more close than would appear from the statistics presented.

DR. JACOBI expressed the view that it is not so much over-study that exercises an influence in the development of chorea, as it is the conditions associated with denutrition. A large number of other diseases is observed in March and April; at that time of the year the system is run down because of deprivation of fresh air during the winter, ill-nutrition, and sundry other causes. Dr. Jacobi has always believed in the intimate connection between chorea and rheumatism, especially since most of these cases of cardiac disease must be due to rheumatism, although the diagnosis is not made. Infantile rheumatism is overlooked, because infants do not have pronounced symptoms; but in a number of cases in which articular rheumatism exists, chorea and heart-disease are present. The joints are not always examined; the frequency of heart-disease in these cases, however, shows a connection. Growing pains are often doubtless rheumatic, and the subsequent history proves them to be so.

DR. LYMAN expressed his belief in the close connection between chorea and rheumatism.

In reply, DR. LEWIS stated that he could not see how, when spring comes, chorea begins if the confinement of the winter has produced it.

DR. W. H. THOMPSON, of New York, read a paper on "The Significance of Intermission in Functional Nervous Diseases." He stated that all derangement of nervous structure must indeed produce derangement of function, but that the reverse of this statement is not always true. Symptoms are often absent in clear cases of disease. Finer methods of microscopic study often prove that disease is dependent upon structural changes, but intermission in disease cannot be explained by the theory of such structural changes. Structure is not enough to explain the working of a mechanism; something more is always demanded—such as a nutritive and energizing fluid or force. Functional nervous poisons have a selective action on various nervous tissues. No drug acts on all tissues alike.

Modern chemistry has shown that auto-infection is a cause of intermittent diseases. A series of poisons is elaborated by the system, the members of which are similar in action to the nerve-poisons of the Materia Medica, and this is illustrated by the action of coline, neurine and muscarine. Natural antisepsis, as of the stomach, intestines and liver, acts antagonistically to the auto-infection arising in these organs, that are subject to nervous influence, and hence the characteristic of intermission is brought about.

DR. S. WEIR MITCHELL read by title the report of "A Case of Crossed Paralysis of the Thermal Sense Without Other Sensory Loss."

DR. H. A. HARE, of Philadelphia, read a paper entitled "A Collective Investigation in Regard to the Value of Quinine in Malarial Hematuria or Malarial Hemoglobinuria." In answer to a series of questions sent to several hundred physicians in malarial districts, Dr. Hare had received 155 answers pertaining to the subject of the paper. It appeared that there was much contradiction in the answers, and that most of the doubt and mystery surrounding the subject yet remained to be cleared up. As a result of the data gathered, Dr. Hare advised that quinine should be given *before*, and not *during* the paroxysm, because of the irritative action on the kidneys. It seems certain that quinine may produce hematuria, as clinical and experimental evidence demonstrate such a relation. Quinine should not be given in hematuria following chronic malarial poisoning.

DR. ATKINSON expressed the view that quinine does not cause hematuria, but that it brings out the idiosyncrasy of the patient in this respect; he has had a number of cases of hematuria without malarial poisoning, and he suggested the query whether hematuria were not due to a parasitic instead of a malarial influence—for example, from the Bilharzia hematobia. In such cases the quinine could do no good. He had found that turpentine was a very excellent remedy. He had looked for filaria sanguinis hominis in these cases, but had not found them.

DR. TYSON urged the value of quinine as a curative agent in the malarial hematuria of moderate type seen in the Middle States; the condition is different in cases of the severe form of the disease. The mischief has then already been done, and quinine will do no good, and the resulting conditions must be treated. Quinine is the proper remedy as a prophylactic. Dr. Tyson's experience confirmed that of Dr. Atkinson, and he advised the use of the natural astringent mineral waters.

DR. STOCKTON alluded to the treatment by large doses of alum that had been advised some years ago for hematuria. In his experience he had found this to be a most excellent remedy in fifteen-grain doses given every hour.

DR. HENRY stated that hemoglobinuria is consequent upon hemoglobinemia, and that there now need be no doubt as to the diagnosis, because we have certain means of ascertaining whether the cause is due to malarial poisoning or not.

DR. VAUGHAN stated that he did not believe that quinine causes hematuria. In Indiana and Michigan it is a common custom to administer tremendous doses of quinine, but cases of hematuria are rare in these States. It would thus seem that some other factor is at work, since the plasmodium of malaria is the same in all parts of the country.

DR. LOVING expressed the belief that the kidney-change had really taken place before the quinine had been administered.

THIRD DAY—MAY 26TH.

DR. STOCKTON read a paper entitled "Misconceptions and Misnomers Revealed by Modern Gastric Research," which was published in THE MEDICAL NEWS of May 28th.

In the discussion, DR. MUSSER urged looking to the

general side of the question as well as to the local, since the gastric condition is often secondary to other conditions; for instance, the general wear and tear is to be considered and the nutrition is to be improved.

DR. LYMAN also emphasized the importance of attention to the general condition, and spoke especially of the arthropathic diathesis, uterine abnormalities, etc., as complicating the gastric condition.

In reply, DR. STOCKTON wished by no means to deny the necessity of general treatment, but especially desired that all treatment should be guided by examination of the stomach and stomach-contents. When the stomach fails in its work, toxemiæ result, with auto-infection. He particularly emphasized the fact that the stomach often manifested no symptoms directly — that the gastric source of the mischief is not always evident, hiding itself under distant symptoms.

DR. CHARLES CAREY, of Buffalo, N. Y., read a paper on "The Production of Tubular Breathing in Consolidation and Other Conditions of the Lungs," which will be published in a subsequent number of THE MEDICAL NEWS. The paper was illustrated by a number of excellent soft-metal castings of the bronchial tubes and bronchioles.

DR. TYSON asked if the rima glottidis might not possibly also contribute to the production of tubular breathing.

DR. MASON spoke of cases in which effusion exists and bronchial breathing does not sometimes take place.

DR. HARE suggested that the elasticity of the openings of the bronchial tubes might be a possible modifying circumstance in producing tubular breathing, rendering the sounds somewhat different from those developed at the edge of the test-tube used in illustration of the phenomenon.

DR. GRIFFITH expressed the belief that the larynx was the primary factor in the production of the bronchial blow; those sounds produced high up were the most pronounced.

DR. LYMAN suggested that a possible modifying factor as regards the pitch of the sound might reside in the increase or decrease in the number of aërial vibrations dependent upon the precipitation downward or elevation upward of the sound produced.

DR. HURD stated that Professor Maull, of Clark University, had been making some excellent casts of lungs, and had found that the bronchi terminated abruptly and in a manner different from that which had usually been pictured.

In reply, DR. CAREY expressed the view that the bronchial "blow" was heard higher up on the right side than on the left, because the first division of the primary bronchus is higher up on this side than on the other.

DR. SAMUEL C. CHEW, of Baltimore, presented a paper entitled "Different Forms of Cardiac Pain." He considered three kinds of such pain: 1. True angina pectoris with increased arterial tension, occurring in paroxysms, and most frequently associated with aortic or coronary disease. 2. Heart-pain from arterio-sclerosis, and often associated with chronic interstitial nephritis. 3. Heart-pain from attenuation of the heart's walls, occurring in different forms of valvular disease that have produced dilatation of the heart. The full text of the paper is to appear in a subsequent number of THE MEDICAL NEWS.

In discussing the paper, DR. STARR stated that a further class of cardiac pain should be added to the classification of Dr. Chew; for example, there was no room in Dr. Chew's classification for the pain of paroxysmal tachycardia; or for that observed in extreme cases of neurasthenia of vasomotor type. Nothnagel has also shown that pain is a symptom in cardiac disease.

DR. MUSSER expressed the opinion that all cardiac pain is anginal in character, and he alluded to cases in which there is pain in the arms without pain in the heart, but with other symptoms of angina. In such cases he advised absolute rest.

DR. MCPHEDRAN stated that he has found nitroglycerin to act better than amyl nitrite in these cases.

DR. STOCKTON expressed his disbelief in the theory that the chief cause of the pain is dilatation of the left ventricle.

The paper of DR. I. N. DANFORTH, of Chicago, on "Tube-casts and their Diagnostic Value," was read by title. It is to appear in a subsequent number of THE MEDICAL NEWS.

The paper of Dr. James C. Wilson, of Philadelphia, on "Pulsating Pleural Effusions" was also read by title, and is to appear in a subsequent number of THE NEWS.

AMERICAN SURGICAL ASSOCIATION.

Thirteenth Annual Meeting, held at Boston, May 31, June 1 and 2, 1892.

FIRST DAY—MAY 31ST. *Morning Session.*

THE President, DR. P. S. CONNER, of Cincinnati, delivered the Annual Address. The ten years of active life of the Association, he said, have been characterized by great extent and accuracy of investigation, by scientific judicious experimentation, by the discovery of important facts, by improvements in the technique of old operations, and by the introduction and general adoption of new procedures. In the study of the causes of disease more positive knowledge has been gained than in all time before, so that in the bacteriologic laboratories a new pathology has been worked out, in large measure revolutionary of both opinion and practice. Speculation and theory have given place to experimentation and fact; and the disease-producing influence of airs, of earths, of waters, have been found to lie in organisms that have been seized upon, separated, classified, and tested.

Since the startling announcement, in 1882, that tuberculosis was dependent upon the presence and action of a definite microörganism that could be isolated, cultivated, and inoculated, a new literature has been written, even a new language created, in which the word "strumous" (except as a synonym of tuberculous) has no more place than the word "phlogiston."

The long-known chronic affections of bone, of joints, of glands, of skin, have been shown to be in great measure the result of the presence and action of a bacillus that everywhere and under all circumstances moves in the same destructive way, though antagonized at every step by the healthy tissues (not seldom successfully), and subject more or less completely to the power of the medical art, directed to the destruction or encapsulation

of the germ, the removal of the infected tissues, or the taking away of the affected part.

The most important work that has been done in connection with surgical tuberculosis is that which has had for its object the discovery and the proper application of a therapeutic agent that will destroy the organism and secure its expulsion from the body or secure such condensation of non-infected tissue about it as shall form a wall and by encapsulation render it harmless. Far better will it be to administer generally or locally a remedy that will remove the bacillus or make it innocuous than to do the most brilliant operation followed by the most rapid healing and recovery in large measure of functional integrity. The end is far from having been reached, but a long step in advance has been made.

Of the three wound-complications that from the earliest times have been the bane of surgery—septic infection, erysipelas, and tetanus—the cause of only the first had been determined a decade ago; that of each is now known.

It is in the treatment of the diseases and injuries of the viscera and their envelopes, however, that the greatest advances in medical art have been made in recent years.

The abdominal cavity, which for so long a time was an almost sacred territory, not to be invaded except under peculiar circumstances and for the relief of a very few morbid conditions, has, because of the secured protection against sepsis, become one of the more common fields of operation in connection with wounds, tumors, obstructions, and infective inflammation.

Penetrating and perforating wounds of the hollow and solid viscera are no longer treated solely by opium and ice with a resulting fatality truly appalling, but by section of the wall, suture of the wound, ligation of the bleeding vessels, and antiseptic plugging, if necessary, of openings in the solid organs. The mortality-rate is still, unfortunately, very high. Not a few of the deaths have been due to the delay, the incompleteness, and the imperfection of the operation, but many must be credited to the damage primarily done. Made by missiles of other than the smallest caliber, a gunshot wound of the stomach, of the intestines, of the mesentery, or of the liver, is likely to prove mortal from shock or hemorrhage, even though treated properly and skilfully, and is almost absolutely certain to do so if fecal extravasation has occurred and septic inflammation has set in. Wounds made by very small balls may be, and have been, recovered from without operative interference, and there is good reason for believing that in the absence of symptoms of active hemorrhage such wounds will do as well, or better, without as with laparotomy. It is as unwise as it is untrue to declare that there are no dangers attendant upon incision of the abdominal walls and exploration of the intestinal tract.

The septic inflammations about the head of the colon, originating so generally in the appendix, have been brought within the province of the surgeon, not, as before, at a late day when the resulting abscess has fortunately come well forward toward the surface, but at an early stage, when, by evacuation of the fluid, with or without removal of the appendix, relief may be afforded and the patient be protected against the lethal effects of perforative peritonitis or perinephritic suppuration. The cases of acute disturbance in the region of the cecum, due to an overloaded bowel or to catarrhal inflammation, will find relief in the future, as in the past, in the therapeutic measures of the physician; but suppurating gangrene producing appendicitis can with safety be treated only by the knife. Whether or not it is advisable to remove, during a quiescent stage, the appendix that has been the seat of repeated attacks of inflammation, is a question as yet unsettled.

An immense amount of work, experimental and operative, has been done in the determination of the proper and most advisable methods of treatment in cases of obstruction, acute and chronic, malignant and non-malignant, at any part of the gastro-intestinal tract. Strictures have been dilated, affected areas removed, anastomosis secured, "cut-offs" established, new openings formed, with the result in favorable cases of effecting cure or affording relief.

Pyloric stenosis, for which ten years ago pylorectomy was all that the surgeon could offer, may now, if of non-malignant character be relieved by digital divulsion through the open stomach, by curetting, by a pyloroplastic operation, or by gastro-enterostomy; and if due to malignant disease, by the latter operation, in every way to be preferred to excision of the carcinomatous mass, being speedier and easier of execution and having a mortality-rate but one-half or perhaps only one-fourth as great. There is a strong and growing feeling that the employment of approximation plates of decalcified bone, of leather, or of potato, or catgut rings or mats, is not only not necessary but rather injurious than otherwise. It is doubtful if operations for carcinoma of the stomach have really been or can be of much service. They certainly have often afforded much temporary relief and are to be resorted to when suffering is great and starvation is imminent; but, on the other hand, the prolongation of life when the operation is recovered from is, with only now and then an exception, but slight.

Malignant disease located in the rectum, too low to be removed through an anterior abdominal incision and too high to be thoroughly extirpated through a perineal one, may be reached from behind after resection of the coccyx, with or without, as necessity may require, resection of the lower portion of the sacrum.

In no other part of intestinal surgery has more been done in thought, in experiment, and in practice, than in that dealing with excisions of the bowel in continuity, rendered necessary on account of wounds, growths or gangrene. As the technique of the operations has been improved, the time of performance has been lessened, the risk to life diminished, and the range of applicability increased. It is still undetermined whether end-to-end or lateral anastomosis is to be preferred; of how much value bone plates or rings or other like aids really are, to the patient at least; how far omental grafts may be required, or how much additional security they afford.

The solid organs have again and again been brought under surgical treatment on account of wounds, of growths, and of tuberculous, parasitic, and suppurative diseases. The kidney, spleen, and even the pancreas, have been removed entirely, the liver in part. The gall-bladder has been opened and its contents removed,

and later sutured and left in place or stitched to the abdominal wall or cut away altogether. Pancreatic cysts have at times been extirpated, at times drained.

The supra-pubic section is now held in high esteem. The treatment of tumors of the bladder has greatly improved and has become more successful. Litholapaxy has taken an established position as the most generally applicable method of dealing with stone, even in young children.

Little has been done in intra-thoracic surgery. Pulmonary abscesses have been evacuated and hydatid cysts have been removed. In a small number of cases pneumonotomy has been performed for tuberculous abscess. Pneumonotomy has been experimentally shown to be easy of performance and attended with no great danger; it will in the future doubtless have a place in the treatment of lung-injuries.

It is in the surgery of the head and spine that the greatest advances have been made, the largest number of new procedures introduced, the most brilliant operations performed; and in these regions more than anywhere else, the surgery of to-day is a new surgery. More and more constantly are all depressed fractures of the skull being treated actively, and basal fractures antiseptically. Stronger and stronger is becoming the conviction of surgeons that fractures of the spine associated with evidence of pressure upon or injury of the cord should not be left to Nature, if the general and local symptoms indicate lesions that can be removed or relieved by elevation or extraction of vertebral fragments, or the lessening of intra-dural tension by opening the sheath.

It has been proved wise to treat bullet-wounds of the brain like other punctured wounds of the organ, by exploring, cleaning, and draining the track; and occasionally it has been found possible to extract the ball through the wound of entrance or a counter-opening in the skull.

Trephining for epilepsy following injury of the skull is no new operation, but of late such treatment has been quite largely employed, not only in cases in which there has been an old fracture or contusion, but in those in which by application of the now well-established rules of cerebral localization, it has been possible to determine the place of a meningeal thickening or of a limited chronic encephalitis, or a new-growth, solid or cystic, acting as an exciting cause of motor disturbance.

Trephining has also been practised for the relief of long-standing severe headache.

Considerable sections of the skull have been taken away to permit of the expansion of the microcephalic brain, but though improvement in the mental condition has followed in certain cases, the operation seems to be of questionable utility. Further investigation must be made into the causes of arrested cerebral development, and as to how far it is productive of, and how far consequent upon premature ossification of the cranium.

Insanity of traumatic origin has, in a very large proportion of the few cases surgically treated, been much improved or cured.

The lateral sinus has been successfully opened in several cases for the removal of pyogenic thrombi.

In not a few cases intra-cranial abscesses have been definitely located and operatively relieved.

The most brilliant chapter in the history of brain surgery in recent times, however, is that relating to tumors. It has become possible to locate, with close approximation to exactness, the position of the neoplasm and its character.

Much less operative work has been done upon the spine than upon the head. Abscesses have been evacuated for the relief of paralysis. Tumors pressing upon the cord have been removed.

Congenital malformations, meningocele, encephalocele, and spina bifida, have been subjected to surgical treatment, with increasing success as improvements have been made in the methods of execution. Renewed attempts have been made to permanently get rid of intra-ventricular effusions by tapping and drainage, but the results have not been what might be desired, whether the old route to the ventricle has been followed or the new lateral one.

DR. JOHN B. ROBERTS, of Philadelphia, read a paper entitled "The Treatment of Uncomplicated Fractures of the Lower End of the Humerus." The following are the conclusions presented:

In the treatment of fractures of the lower extremity of the humerus, the divergent angle between the axes of the arm and forearm must be preserved; and hence dressings that interfere with the normal difference in the level of the radius and ulna are not permissible.

Fractures of the lower extremity of the humerus of ordinary severity are, as a rule, more successfully treated in the extended than in the flexed position, because the "carrying function" is less liable to be impaired.

Passive motion at an early date is harmful; and should be deferred until union has occurred and the dressings have been finally removed.

Good results as to anatomic conformation and as to motion are generally to be expected and can usually be obtained.

Recent fractures in which satisfactory coaptation is not obtainable under anesthesia may with propriety be subjected to exploratory aseptic incisions. Old fractures in which deformity and impairment of function are marked, may, within certain limitations, be subjected to re-fracture or osteotomy, for the relief of these conditions.

DR. JOHN E. OWENS, of Chicago, stated that he had never treated fractures of the lower extremity of the humerus in the extended position. The treatment of such fractures in the extended position seems to recommend itself for the following reasons: In the extended position there is no room in the olecranon fossa for neoplastic deposits; the superabundance of soft tissues in front of the joint when the arm is flexed masks the symptoms; the soft tissues in front of the arm present more opportunity for laceration and cicatricial contraction; in the extended position no traction is made upon the vessels and nerves; and the natural angularity between the arm and forearm is preserved.

Dr. Owens had experienced considerable timidity in the treatment of fractures at the elbow, on account of the impaired mobility that often results. The natural position of the arm in relaxation is one of flexion. He had treated these fractures in the flexed position. The extended position may cause tilting forward of the upper extremity of the lower fragment or its rotation forward, or hyper-extension may be caused.

Passive motion is resorted to in four or five weeks to an extent short of causing suffering. The material used for the splint is plaster-of-Paris. Dr. Owens had treated many of these fractures in cases in which the injury resulted from railroad accidents, and in which suits for damages are common, but he knew of no case in which the question of defective treatment entered successfully.

DR. JOHN H. PACKARD, of Philadelphia, remarked that it was often difficult to tell the exact character of a fracture at the elbow-joint even under the most favorable opportunities for examination. He thought that the carrying function was rarely perfectly maintained under any plan of treatment. After fracture running into the joint there is liability to the formation of adhesions. He thought that passive motion should be resorted to before the organization of these adhesions. He advocated treatment of these fractures in the flexed position, and described a splint of sheet zinc that he had used with satisfaction.

DR. CHARLES B. PORTER, of Boston, contended that the treatment advocated in the paper violated one of the first principles in the treatment of fracture—that is, to place the muscles in a state of relaxation. In the extended position the muscles that should be relaxed are not at rest. He had never seen any statistics in regard to the results of treatment of fracture in the extended position, in comparison with those treated by the the flexed position. Until these are forthcoming, the profession will be unwilling to accept this as the best method of treatment. He therefore adhered to the treatment of these fractures in the flexed position. Before the fracture is dressed, it should be adjusted under ether and then not disturbed for two or three days, and, if found in position, not again dressed for a week or ten days. In old fractures, if there is sufficient deformity to demand osteotomy, resection of the elbow is better and may secure a very useful arm.

DR. J. FORD THOMPSON, of Washington, D. C., expressed his disapproval of the plan of treating fractures of the lower extremity of the humerus by means of a right-angled splint. In his practice he adopted that plan of treatment which permitted the axes of the fragments to be brought into relation with each other. This he had found to be the extended position. In two cases of compound fracture he had been unable to bring the fragments into line until the forearm was extended. The difficulty about the extended position is that it is disagreeable and uncomfortable to the patient. He considered plaster-of-Paris to be the best dressing.

DR. A. G. GERSTER, of New York, maintained that the bad results that are often seen after fractures at the lower extremity of the humerus, are not necessarily due to the method of treatment. In several cases in which he had had an opportunity to examine the joint, he had found that the trouble was due to the throwing out of callus at points where the callus has been stripped off. Bad results are also often due to insufficient examination. Anesthesia is not employed, and the dislocation that may accompany the fracture is not recognized. In the treatment of the fracture, after replacing the fragments, such methods must be employed as will hold the fragments in place. The flexed or extended position must be employed as necessary. He had found that, as a rule, the fragments were best held in place by treatment in extension. He does not employ passive motion, and considers it useless and often harmful.

DR. STEPHEN H. WEEKS, of Portland, Me., stated that it was his custom to treat supra-condyloid fractures of the humerus in a position of flexion, but he was satisfied that satisfactory results are secured by different methods of treatment.

DR. T. J. DUNOTT, of Harrisburg, Pa., expressed the opinion that the manner in which the injury had been received had much to do with the ultimate result. The flexed position would give a good result in many of these fractures associated with severe injuries. He prefers to treat the arm in such a position that the radius and ulna are parallel. In many cases in which great injury is done to the soft parts no splint can be applied, and under such circumstances the arm should be laid on a pillow and lead-water and laudanum applied for some days, until the tumefaction subsides. If necessary, incision into the tense tissues is made.

DR. W. H. CARMALT, of New Haven, stated that in some cases the ulna acted as a wedge between the two fragments at the lower extremity of the humerus, forcing them apart, and reported a case recently treated in the flexed position, extension being employed by means of weights, a satisfactory result having been obtained.

DR. J. COLLINS WARREN, of Boston, stated that he had observed the difficulty mentioned by Dr. Carmalt, but had attributed it to drawing forward of the condyles rather than to sinking in of the ulna. Dr. Bigelow had laid down the excellent rule of going through the movements for reducing a dislocation at the elbow in these cases. In this way the danger of overlooking a dislocation is avoided, and if there is simply a fracture the manipulations mould the bone into place. The flexed position, with an internal angular splint, seems to be the best method.

Afternoon Session.

DR. JOHN B. ROBERTS, of Philadelphia, read a paper entitled "The Treatment of Uncomplicated Fractures of the Base of the Radius." The following conclusions were presented:

Fractures of the lower extremity of the radius vary comparatively little in their general characteristics, because but one form is usual.

Muscular action has little or nothing to do with producing or maintaining the deformity.

Immediate reduction of the fragments is the essential of treatment.

Many of the splints devised for the treatment of this fracture have been constructed in ignorance of the pathology of the condition.

The ordinary fracture of the lower extremity of the radius usually requires no splint, and should be dressed with a wristlet of adhesive plaster or bandage.

When a splint is required, a narrow, short dorsal splint, fixing the wrist, is all that is necessary.

The method of dressing here advocated is the best, because it annoys the patient as little as possible, by avoiding cumbersome appliances, and permits free voluntary movements of all the finger-joints.

Passive motion is unnecessary until union has occurred and the dressings have been finally removed.

Good use of the wrist and fingers is early obtained,

and the anatomic conformation is restored as well as, and perhaps better than, by other more complicated dressings.

Old fractures which have been improperly treated, by omission of immediate reduction, may with considerable success be subjected to re-fracture at the expiration of six weeks or more. At later periods readjustment may be possible only by osteotomy, which is a legitimate means of treatment.

DR. JOHN H. PACKARD, of Philadelphia, stated that in 1879 he had read a paper on this subject before the American Medical Association, in which he took the ground that the great difficulty in many of these cases arose from non-reduction. If the fracture of the lower extremity of the radius, commonly known as Colles's fracture, is once reduced, there is little tendency to reproduction of the deformity. Many physicians think that all that is necessary is to apply the proper dressing. The most important step in the treatment is reduction. He did not agree with the fifth proposition, that no splint is required. He employs an anterior splint padded to fit the curve of the radius and reaching to the ball of the thumb. The patient can use the fingers freely. In ordinary cases this simple splint suffices.

DR. CHARLES B. PORTER, of Boston, emphasized the necessity of complete anesthesia, then complete reduction and breaking up of the impaction, and then the application of posterior and anterior splints; after a week or ten days he allows motion of the fingers, and in two weeks motion at the wrist. He considers passive motion unnecessary, except in old people in whom there is a rheumatic or gouty tendency.

DR. J. FORD THOMPSON, of Washington, dwelt upon the disastrous results that often followed failure to reduce the displacement, or the use of improper dressings. After reduction of the fragments he applies anterior and posterior splints secured lightly to the arm. He had not, as a rule, found it necessary to employ ether to facilitate reduction. In cases in which there was severe pain following the application of the ordinary splint, instant relief followed the application of a plaster splint, the hand being carried well to the ulnar side. In several cases in which the hands were useless from the inflammation of the sheaths of the tendons he had tried to break the adhesions up under repeated administration of anesthetics, but the results had not been decided.

DR. JOSEPH RANSOHOFF, of Cincinnati, stated that in some cases the reduction could not be effected so readily as had been indicated. He had had three or four cases in which extension would not overcome the difficulty, and in such cases hyper-extension was resorted to. In the treatment he is partial to the Levis splint. After a week or ten days passive motion is resorted to.

DR. CHARLES B. NANCREDE, of Ann Arbor, called attention to the fact that a certain amount of the bone-tissue at the seat of fracture is destroyed, so that some deformity will necessarily follow. Reduction is the most important measure in the treatment. The fragments are then to be held in place by suitable apparatus.

DR. JOHN HOMANS, of Boston, read a paper on "Fibroid Tumors of the Uterus," which will be published in a subsequent number of THE NEWS.

(To be continued.)

CORRESPONDENCE.

A CORRECTION FROM DR. WOOD.

To the Editor of THE MEDICAL NEWS,

SIR: I beg to correct an error into which your reporter (MEDICAL NEWS, May 28th, p. 605) has fallen as to my advice in regard to the disposal of homicidal maniacs. I did not say what is attributed to me. In substance, I said that it was justifiable to put to death certain homicidal maniacs whose whole lives are given up to planning to kill their attendants, and that it was not right to tax people to pay others to risk their lives in feeding and otherwise taking care of such human tigers.

H. C. WOOD, M.D.

1925 CHESTNUT STREET.

NEWS ITEMS.

The British Medical Association will hold its sixtieth annual meeting at Nottingham, July 26, 27, 28, 29, 1892.

The "Address in Medicine" will be delivered by Dr. James Cuming, of Belfast; the "Address in Surgery," by Dr. W. H. Hingston, of Montreal; the "Address in Bacteriology," by Dr. German Sims Woodhead, of London.

In the Section of Medicine a discussion on "Peripheral Neuritis" will be opened by Dr. J. S. Bristowe.

A discussion on "The Prognosis and Treatment of Ascites" will be opened by Dr. W. B. Cheadle.

The following papers are announced:

"On the Value of Perimeter Measurements in the Diagnosis of Local Brain Disease," by Dr. Byrom Bramwell. "On Some Complications and Sequelæ of the Infectious Fevers," by Mr. Francis Hawkins. "Subacute Non-rheumatic Myocarditis," by Dr. Laurence Humphry. "Treatment of Pneumonia by the Ice-bag," by Dr. D. B. Lees. "The Association of Sensory Disorders with Visceral Disease," by Dr. J. Mackenzie. "Note on the Relief of Ascites by Establishing a Fistulous Communication with the Rectum by Operation," by Dr. Murray. "Peripleuritis," by Dr. P. Blaikie Smith.

In the Section of Surgery a discussion on "The Surgery of the Thorax" will be opened by Mr. Rickman J. Godlee. A discussion on "The Surgery of the Liver and Gall-bladder" will be opened by Mr. A. W. Mayo Robson. A discussion on "The Treatment of Spinal Abscess" will be opened by Mr. W. Watson Cheyne.

The following papers are announced:

"On Appendicitis," by Mr. H. Gilbert Barling. "On Rectal Cancer," by Mr. Harrison Cripps. "The Restoration of the Lost Function of Micturition," by Mr. Reginald Harrison. "The Later Results of Laminectomy for Angular Curvature," by Mr. W. Arbuthnot Lane. "On Pancreatic Surgery," by Mr. Jordan Lloyd. "A Case of Simultaneous Ligature of the Subclavian and Common Carotid Arteries for Aneurism of the Innominate Artery," by Dr. C. H. Marriott. "A Case of Supra-pubic Lithotomy," by Dr. W. Newman. "On the Use of the Omentum in Intra-peritoneal Operations," by Dr. N. Senn. "Practical Points in the Surgery of Cancer," by Dr. Herbert Snow. "A Review of Twenty-

five Cases Illustrating the Surgery of the Thyroid Gland," by Dr. C. J. Symonds. Mr. J. R. Morison will exhibit (1) a specimen from a successful case of ileo-colostomy for chronic ileo-colic intussusception; (2) a specimen from a case of combined excision of the pylorus and gastro-enterostomy.

In the Section of Obstetric Medicine, a discussion upon "The Treatment of Uterine Fibroids" will be opened by Mr. J. Knowsley Thornton. A discussion on "Post-partum Hemorrhage" will be opened by Mr. G. E. Herman.

The following papers are announced:

"The Proper Use of Midwifery Forceps," by Dr. A. E. Aust-Lawrence. "A Consideration of the Less Obvious Causes of Retardation in the First Stage of Labor," by Mr. W. Bain. "Note on a Case of Cystocele Treated by Stoltz's Method," by Mr. E. S. Bishop. "Ergot as a Muscular Tonic during Pregnancy," by Mr. F. Borough. "On a Case of Total Extirpation of the Uterus through the Vagina for Cancer, with the Result One Year after the Operation," by Mr. W. J. Cant. "The Medicinal and Mechanical Methods of Expediting Pregnancy," by Mr. J. Dysart McCaw. "On the Electrical Treatment of Uterine Fibroids, Scientifically Considered," by Dr. H. McClure. "On Post-partum Hemorrhage," by Dr. I. More Madden. "Stoltz's Operation for Cystocele," by Dr. A. D. Leith Napier.

In the Section of Public Medicine the following subjects are suggested as suitable for discussion, but the list is open to modification: 1. "Legal Restraint upon the Employment of Women in Factories before and after Childbirth." 2. "The Use and Abuse of Infantile Insurance." 3. "Coroner's Inquests." 4. "Disposal of the Dead in the Future; Cemeteries and Crematoria." 5. "The Future of Hospital Isolation for Infectious Diseases." 6. "The Isolation of Measles." 7. "The Notification of Erysipelas and Puerperal Fever." 8. "The Diminished Mortality from Scarlet Fever." 9. "Is Smallpox Dying Out in the British Isles?" 10. "Endemic Typhoid." 11. "Epidemic Alternations." 12. "Offensive Trades in Towns." 13. "Methods of Dealing with Town Refuse in the Midst of Populated Districts." 14. "Ventilation of Town Sewers." 15. "The Condemnation of Tuberculous Meat: to what Extent should this be Carried?" 16. "Relation of Medical Officer of Health to the Sanitary Staff." 17. "Epidemic Influenza; the Attitude of Public Authorities toward it."

The following papers are announced:

"A Contribution on the Condemnation of Tuberculous Meat," by Dr. J. S. Cameron. "On the Influenza Epidemics of 1891–2 Considered Mainly from a Statistical Standpoint," by Dr. F. A. Dixey. "Contribution on Disposal of the Dead in the Future," by Mr. Joseph Loane. "On an Epidemic of Cerebro-spinal Meningitis," by Mr. H. G. H. Monk. "On Epidemic Enteric Fever," by Dr. Scott Tew.

In the Section of Psychology, the President, Mr. William Bevan Lewis, will deliver an Introductory Address.

The two following subjects have been chosen for special discussion: 1. "Psychoses after Influenza," to be opened by Dr. Julius Althaus. 2. "Insanity as a Plea for Divorce," to be opened by Dr. Lionel A. Weatherley.

The following papers are announced:

"Variations in Type of General Paralysis," by Mr. F. St. J. Bullen. "Minor Psychical Disturbance in Women," by Dr. Harry Campbell. "Paranoia and its Relationships," by Dr. Dunn. "The Pathological Anatomy of Acute Encephalitis: an Experimental Study," by Dr. Edwin Goodall. "On Microcephaly," by Dr. Robert Jones. "The Value of Hypnotism in Chronic Alcoholism," by Dr. C. Lloyd Tuckey.

In the Section of Pathology the following papers are announced:

"Variability of Microbes," by Mr. J. G. Adami. "Carcinoma of Mamma," by Mr. Cecil Beadles. "Phagocytosis in Relation to Erysipelas, by Mr. T. J. Bokenham. "1. Experimental Epilepsy; 2. Theory of Tumors; 3. Specimens," by Dr. C. Boyce. "Macro- and Microscopic Preparations of Pathological Brains and Spinal Cords, with Lantern Demonstrations," by Dr. Alexander Bruce. "Dystrophia Muscularis," by Dr. Alexander Bruce and Dr. John Thompson. "Museum Casts," by Mr. C. W. Cathcart. "1. Ataxic Paraplegia; 2. Endothelioma of the Dura Mater," by Mr. Mitchell Clarke. "Morbid Conditions of Stomach in Phthisis," by Dr. Soltau Fenwick. "1. Pathology of Jaundice; 2. Pathology of Diabetes," by Dr. Vaughan Harley. "Edema," by Mr. Victor Horsley. "Cerebral Tumor," by Dr. Laurence Humphry. "Carcinoma of Mamma," by Mr. Raymond Johnson. "Pathology of Chlorosis," by Dr. E. Lloyd Jones. "1. Immunity; 2. Specimens of Madura Disease," by Mr. A. A. Kanthack; "Experimental Diphtheritic Paralysis," by Dr. Sidney Martin. "Myxedema," by Mr. George Murray. "Leukocythemia," by Dr. Muir. "Researches in Cancer Pathology," by Dr. Herbert Snow. "Carcinoma of Mamma," by Mr. Harold Stiles. "Diabetes," by Mr. H. J. Tylden. "Morbid Conditions of Bone," by Dr. Alexis Thomson. "Rate of Beat of the Heart in Health and Disease," by Prof. C. J. Roy. "1. Typhoid Fever in Animals; 2. Paralysis from the Poison of Bacillus Pyocyaneus," by Dr. A. Ruffer.

In the Section of Ophthalmology a discussion on the "Treatment of Diseases of the Lachrymal Apparatus" will be opened by Mr. Charles Higgens.

The following papers have been announced:

"Prolapse of the Iris after Simple Cataract Extraction, and its Treatment," by Mr. W. J. Cant. "The Registration of Defects of Color Perception," by Dr. W. F. Edridge-Green. "Notes on a Case of Tumor of Right Orbit; Operation; Recovery," by Dr. J. Farrar. "1. Some Improvements in Perimetry; 2. A Modification of Foerster's Box for Testing the Light-sense; 3. The Treatment of Cataract Extraction and other Wounds by Antiseptics," by Mr. M. B. Fergus. "Chloride of Sodium as a Direct Agent in the Production of Cataract," by Mr. A. V. Ford. "1. Ten Years' Experience of the Effects of the Treatment of Interstitial Keratitis by Syndectomy without the Use of Specific Drugs; 2. A New Operation for the Treatment of Eversion of the Lower Lids Associated with Granular Lids; 3. Further Researches into the Localization of Headaches Due to Various Forms of Ametropia, including Cases of Vertigo, *Petit Mal*, and True Epilepsy, Cured by the Use of Correcting Lenses," by Mr. H. B. Hewetson. "The Pathology of Some Intra-ocular Tumors," by Mr. J. B. Lawford.

"Note on the Relationship of Convergence to Accommodation," by Mr. A. S. Percival. "The Operative Treatment of Trachoma," by Mr. S. Stevenson. "A Complicated Case of Monocular Hemiopia," by Mr. S. J. Taylor. "A Primary Sarcoma of Iris, with Microscopic Sections," by Mr. G. E. Williamson.

In the Section of Diseases of Children, a discussion upon "The Diagnosis and Treatment of Croupous Pneumonia in Children" will be opened by Dr. James F. Goodhart. A discussion on "The Treatment of Severe Club-foot" will be opened by Mr. J. Walsham.

Mr. E. L. Freer will read a paper on "The Treatment of Scoliosis."

In the Section of Pharmacology and Therapeutics a discussion on "Cardiac Tonics and the Indications for their Use" will be opened by Dr. William H. Broadbent. A discussion on "Dyspnea and its Treatment by Drugs" will be opened by Professor W. T. Gairdner.

Prof. Liebreich, of Berlin, has deputed Dr. A. P. Chadbourne to present a communication reporting, the outcome of researches in the laboratory of the former.

In the Section of Laryngology a discussion upon "The Etiology, Pathology, and Treatment of Nasal Neuroses" will be opened by Dr. Donald Stewart and Dr. Adolf Bronner. A discussion upon "Catarrh of the Nose and Throat; its Etiology, Pathology, and Treatment" will be opened by Mr. J. Macintyre. A discussion upon "Granular Pharyngitis; its Etiology and Treatment," will be opened by Mr. T. Mark Hovell.

Mr. Mayo Collier will read a paper on "The Causation of Deflections and other Irregularities of the Nasal Septum;" Dr. Watson P. Williams, a paper on "The Dyspeptic Sore-throat."

Preliminary Program for the Section on Dermatology and Syphilology of the American Medical Association.—

Address by the Chairman, Dr. Bulkley: Recent Advances in the Treatment of Diseases of the Skin.

Louis A. Duhring, M.D., of Philadelphia: Local Treatment of Acute Vesicular Eczema.

C. P. Russell, M.D., of Utica, N. Y.: Eczema of Infancy and Childhood, with Special Reference to Etiology and Dietetic Treatment.

L. Duncan Bulkley, M.D., of New York: Diagnosis and Treatment of Eczema Seborrhoicum.

The Medical Society of the State of Washington held its third annual meeting at North Yakima, May 11th and 12th.

The following papers were read: "Report on Practice of Medicine," by C. K. Merriam, of Spokane; "Typhoid Fever and its Treatment," by C. P. Thomas, of Fairhaven; "Report of a Case of Leprosy," by H. C. Willison, of Port Townsend; "Report of Eight Major Amputations," and "Report of a Melanotic Sarcoma of Neck," by J. B. Eagleson, of Seattle; "Report on Ophthalmology and Otology," by A. B. Kibbe, of Seattle; "Some Practical Points on Diseases of the Ear," by L. R. Thomson, of Spokane; "Sympathetic Ophthalmia," by G. H. Mauzey, of Spokane; "Treatment of Immature Cataract by the Kalisch Method," by G. S. Armstrong, of Olympia; "Report of Four Laparotomies," by C. A. Smith, of Seattle; "Treatment of Epilepsy," by C. W. Sharples, of Seattle; "Report on History and Necrology," by G. A. Weed, of Seattle.

The following officers were elected for the ensuing year: *President*, N. Fred. Essig, of Spokane; *First Vice-President*, G. S. Armstrong, of Olympia; *Second Vice-President*, F. M. Bell, of Kelso; *Secretary*, G. D. Shaver, of Tacoma; *Treasurer*, J. B. Eagleson, of Seattle.

The next meeting will be held at Tacoma on the first Wednesday in May, 1893.

The Philadelphia Alumni Society of the Medical Department of the Univereity of Pennsylvania held its first regular meeting at the Colonnade Hotel, Fifteenth and Chestnut Streets, on Saturday evening, May 14th. This Society is a local branch of the parent Alumni Society as provided for in Article VIII. of its constitution, and has elected the following officers:

President: Dr. Roland G. Curtin.

Vice-Presidents: Dr. Edward L. Duer, Dr. S. D. Risley, and Dr. Henry Beates, Jr.

Recording Secretary: Dr. Ellwood R. Kirby.

Corresponding Secretary: Dr. Benj. F. Stahl.

Treasurer: Dr. Joseph P. Tunis.

Executive Committee: Dr. Judson Daland, Dr. A. C.

Wood, Dr. Richard Norris, Dr. William R. Lincoln, and Dr. Harry Toulmin.

It is proposed to hold four meetings during the year, on the second Saturday of the months of November, January, March, and May, which shall be largely of a social character. Already the plan has been heartily indorsed by a large number of graduates, and more than one hundred and twenty-five men have signed the constitution.

Action of the Pennsylvania State Medical Society as regards Nostrums.—At a meeting of the Philadelphia County Medical Society, held May 25, 1892, Dr. John B. Roberts, President, reported that the Medical Society of the State of Pennsylvania had unanimously adopted the resolutions sent up by the Philadelphia County Society, in condemnation of the practice of giving certificates to secret medicines, and of the action of the *Journal of the American Medical Association* in publishing advertisements of such preparations. On motion it was resolved to print one thousand copies of the resolutions of Dr. S. Solis-Cohen's paper, offering the same for distribution at the Detroit meeting of the American Medical Association.

The American Climatological Association will hold its ninth annual meeting at Richfield Springs, N. Y., June 23 and 24, 1892.

CORRECTION.

In the table on page 577 of THE NEWS of May 21, 1892, it was intended to say that "hydroleine" contained salicylic acid, not "salicylic alcohol."

FIBROID TUMORS OF THE UTERUS.[1]

BY JOHN HOMANS, M.D.,
OF BOSTON, MASS.

THIS paper is not, in any sense of the word, a treatise or an essay on fibroid tumors, but simply an account of their natural history as I have watched them, their effect on the women that have had them, the means that may be employed when necessary to remove them, and the condition in which patients are left after operation. Nor have I thought it necessary to enumerate and tabulate all my own cases, although this might be interesting to the Association and instructive to me, but I have simply illustrated my remarks by citing a few descriptions applicable to the subject mentioned.

I suppose it is unnecessary for me to define a fibroid tumor of the uterus. We all know them to be aggregations of normal uterine tissues in abnormal situations and masses. They may cause symmetrical enlargement of the uterus, or more or less one-sided enlargement; they may be in the walls of the uterus, or protruding toward its outside, or toward its inner cavity; they may be incorporated with the uterus, or connected with it by a broad attachment, or by a pedicle; or they may be entirely separated from it, and get their nourishment from the vessels of the omentum or mesentery, to which they are adherent; they may grow under the broad ligament, or they may grow directly out into the general cavity of the peritoneum. Certain of them that grow near the cornu of the uterus are sometimes gradually extruded until they are merely connected with the uterus by the Fallopian tube and broad ligament, and have a pedicle as distinct as that of an ovarian pedicle. I have seen this state of things three times, and always on the right side.

Uterine fibroids may be dense or edematous, or filled with lymph-spaces, or they may, in very rare instances, be fibro-cystic, having true cysts as distinct as those in an ovarian tumor, not the dilatations in the substance of the tumor—already mentioned, which are filled with clear yellow or bloody fluid and are simply dilated lymph-spaces, but fibroid tumors, having true cysts on their outer surfaces, with thin walls, and filled with fluid of different densities. I am of the opinion that a certain number of tumors that have been described as fibro-cystic belong to the class I have mentioned as fibroids with dilated lymph-spaces. True fibro-cysts are very rare, and I should say that a frequent operator would not meet with more than one or two in many hundred cases of uterine tumors.

In size these tumors vary from that of a mere dot to masses weighing fifty or more pounds. Their rate of growth is generally slow, by which I mean that several years' growth will be required to produce a tumor the size of one's fist. They are very common. In order to settle this question for myself, I have gone over my records of office-patients. I find that I have seen in my office during the past fifteen years 370 cases of fibroid tumors of the uterus, and, as I have seen many at the hospitals and in consultation, I think I may fairly add 150 more, making in all 520 cases. When one surgeon has seen that number in fifteen years, I think they may be called common. These tumors are said to occur more frequently in the black than in the white race, while ovarian tumors are said to be more common in the whites than in the blacks.

Operations to relieve women of fibroid tumors are rarely necessary, judging from my own experience. Of these 520 cases, I have operated only on sixty, or about 11 per cent. The conditions that should guide us in recommending the removal of the tumors are: when they threaten life by hemorrhage; when they are unbearable from their weight, or from the inconvenience they cause, particularly in the act of stooping or bending, or from their position when they prevent a woman from sitting down; when in a young woman they cause distress, chagrin, and shame, from the alteration they have made in her figure; when they cause so much pain as to make life a burden; when by their presence they so obstruct the circulation as to cause swelling and edema of the limbs, or interfere so much with the action of the digestive and eliminative organs as to cause emaciation and weakness; when they block up the pelvis so as to cause obstruction of the bowels; or when they have caused strangulation of the bowel; or when their pedicles have become twisted—and sometimes the whole uterus becomes twisted on its axis exactly as the pedicle of an ovarian tumor does, and presents the same symptoms, and requires immediate operation.

Death by hemorrhage is very rare. I have knowl-

[1] Read at the meeting of the American Surgical Association, held in Boston, May 31, June 1 and 2, 1892.

edge of only three instances. Many women are blanched, and anemic, and feeble, but they live, and most of them are relieved by curetting, or at times by electrolysis *à la* Apostoli, or by the removal of a pedunculated fibroid from the interior of the uterus, or by enucleating a half-extruded one.

The feeling of weight and inconvenience caused by these tumors is sufficient in some cases to call for their removal, and the sufferer has a right to demand operation, even if life is not threatened, for surgery is not only to save life, but to contribute to its comfort; and there is no class of cases in which the decision of the patient has more weight than in these cases of fibroid tumors. "I do not want to carry this thing any longer; it annoys me. I cannot stoop to button my boots, and I want it removed," said a woman to me. I had put her off several months, and she had abundant time to think the matter over. I thought she had a right to decide the question of operation. I removed the tumor, and she got well.

A growing tumor in a young woman of from fifteen to thirty years old, which has distended the abdomen and is prominent and unsightly, and causes remark, may with propriety be removed, if the sufferer cannot bear to know how she looks, even if the tumor gives rise to no symptoms. It is *her* tumor and *her* life, and *her* body and appearance, and she has a right to look like other women if she wants to.

Some large tumors interfere very little with respiration and nutrition, and cause but little edema and emaciation; while others, not so large, cause great debility. Those tumors that have become entirely separated from the uterus are dangerous from the opportunities they afford for strangulation of the intestine, and should be removed. I have seen a case of death caused by some loops of the bowel becoming strangulated by slipping in between points of adhesion formed between a fibroid that had became wholly separated from the uterus and other loops in a tumor nourished solely by its adventitious adhesions. Such loose-lying fibroids should be removed.

Again, a fibroid may threaten to render delivery impossible by the natural passages. At the same time, Nature will generally get these fibroids out of the way if you will give her a chance. I remember a case of this kind in the practice of Dr. John Benson, of Chatham, New Brunswick. It was a first labor; the tumor was so obstructive that Cæsarean section was seriously considered, but at length the tumor receded and allowed the head to pass. A few weeks after delivery, Dr. Benson sent the lady to me. I opened the abdomen, turned the body of the uterus and both ovaries forward upon the pubes, split the capsule of the tumor and enucleated it from its bed, sewing up the rent in the uterus where its pedicle had arisen from the posterior part of the body near its junction with the neck. Recovery was uneventful. The tumor was about six inches in diameter and weighed two and a half pounds; it was growing, and if it had been allowed to remain would undoubtedly have rendered the next delivery impossible.

At the same time, as I have said, Nature will generally lift these tumors out of the way when the attending accoucheur would think natural delivery impossible. I remember a case in which a large fibroid tumor filled the vagina at the beginning or just before the beginning of labor. I could not move it by pressing on it with my hand, even with a purchase against the wall of the room with my feet, and yet in twenty-four hours Nature had pulled that tumor up and had pushed the cervix, through the orifice of which one could feel the child's head, down into the vagina.

I remember another case of pregnancy at five months in which I advised non-interference, but another gentleman said that the tumor must be removed, as delivery at term would be impossible. This was done and the woman died in two hours. In another case that I remember, a practitioner induced labor somewhat prematurely and ruptured the uterus, and the woman died. Both of these cases could not have done worse if they had been let alone, and they might have done better.

Sometimes these tumors, when quite small, by their position make it impossible for a woman to sit down with comfort. One of my patients said she felt as if she was sitting on a spool, and that she had to stand or lie down to have any comfort. She was sent to me by Dr. W. G. Kimball, of Worthington, Mass. A fibroid about the size of a horse-chestnut, on the posterior and left side of the fundus, was tied and burnt off. Another near it, the size of a boy's marble, was torn off. There was no drainage. Rapid recovery and complete relief followed.

The solid fibroid tumors rarely have any adhesions, and are removed without much difficulty after a little practice. The true fibro-cystic tumors are very rare. In the 520 cases mentioned I am only sure that 8 were fibro-cystic—only about 1.3 per cent. Of these, I did not remove any successfully. In all the operations I was unable to separate the cysts from the bowel and other peritoneal structures. One woman recovered from an incomplete operation. The others all died. Of course, there may have been a carcinomatous element in some of these tumors, as very few of them were followed by autopsies. Most of these operations were attempted many years ago, when my manual dexterity was not as much developed as it is to-day;

but I still regard true fibro-cysts of the uterus as very rare, and, as a rule, very dangerous of removal.

An extraordinary case of twisting of the uterus as the pedicle of a large fibroid tumor of many years' existence was reported by me in the *American Journal of Obstetrics*, 1892, vol. xxv, No. 3. The uterus was twisted one and one-half times on its axis, and the blood-supply was cut off from the tumor and from the ovaries and tubes. The case was fatal, no operation having been done. There was general peritonitis and lobular pneumonia. How this twisting of a great solid tumor and of the uterus could have happened is incomprehensible to me. Here was a solid fibroid tumor, weighing at least six pounds, and this, with the body of the uterus, and with both ovaries, tubes, and broad ligaments, was twisted around one and a half times.

The natural history of 90 per cent. of fibroid tumors is to grow to a size to reach the umbilicus, or to reach higher or lower than this point, and then to remain stationary, and after the menopause to become cretaceous and atrophied. Some of them, I think, shrivel up almost entirely, while others remain as large as a cocoanut without giving rise to great inconvenience. About 10 per cent. of them require removal for one of the various reasons I have mentioned in the earlier part of this paper; others atrophy of themselves, without any treatment being employed. A large number of them are discovered by the attending physician, the women being totally unaware of their presence, though they may have been in the womb for many years.

Patients with fibroid tumors present themselves between the ages of twenty and sixty years, rarely before or after these periods of life. The average age of those on whom I have found it necessary to operate is thirty-nine years. One-quarter of them were about thirty-four years old. The youngest patient on whom I have done abdominal hysterectomy for a fibroid was eighteen, and the oldest sixty-five years of age. Of 60 cases, 1 was sixty-five, 1 sixty-three, 10 were between fifty and fifty-two, 1 was eighteen; only 3 were between twenty and thirty, while 44 were between thirty and fifty years of age.

The treatment of these cases may be by drugs or by surgery, or by both, or by letting alone. The most common drug used is ergot. Alone, as a rule, it is ineffectual; combined with curetting, it helps to stop hemorrhage. The treatment by high doses of electricity sent through the uterus and tumor *à la* Apostoli, I have written upon at length elsewhere.[1] Suffice it to say that it sometimes arrests hemorrhage, almost always relieves pain and gives strength, but rarely diminishes the size of the tumor.

[1] Boston Medical and Surgical Journal, vol. cxxiv, March 5, 1891.

Removal of the ovaries for the cure of fibroids, particularly bleeding ones, was at one time extensively practised. I have practised it but four times. In one woman, forty-four years old, the tumor disappeared in a few weeks, and menstruation ceased at once. In another, thirty-three years old, the catamenia gradually ceased after three years, and the tumor remained about the same when I last heard, in 1887. In another woman, thirty-four years old, the operation was done on August 5, 1885. By May, 1886, she had gained twenty-four pounds in weight, and was well and strong. From the time of the operation until November 10, 1885, a period of three months, she flowed incessantly, but slightly, nothing in amount to what she had done before the removal of the ovaries and tubes. From November 10, 1885, until February 24, 1886, the flow wholly ceased. Since the latter date until May 13, 1886, she flowed continually, but not one-tenth as much as she used to. The tumor was somewhat diminished. I have not seen her for six years. Another, thirty-six years old, was not at all relieved by the operation. The tumor reached to the umbilicus, and the flooding was severe. I removed the ovaries and the tubes on January 21, 1886. Two years later the tumor had descended into the cavity of the uterus, and was removed *per vaginam*. Of course, after this the hemorrhage ceased. In another case, not my own, I have seen the tumor grow enormously after removal of the appendages, and I am inclined to regard the method as unreliable.

Curetting the interior of the uterus often cures hemorrhage completely, and this curetting I follow by wiping the interior of the uterus with tincture of iodine. At the present time the surgical treatment is almost wholly by removal of the tumor, with or without the uterus. The kind of operation to be adopted has varied, and will vary with the particular case and the particular operator. In general, the two varieties of the operation are described as intra-peritoneal and extra-peritoneal treatment of the pedicle.

Of course, if the tumor has been gradually extruded more or less into the cavity of the uterus, it should be enucleated and removed under the most careful antisepsis. Such protrusion will invariably be preceded by great hemorrhage, and will give abundant warning of the necessity of interference. Quite large tumors are extruded in this way.

Tumors that have carried the fundus of the uterus to the umbilicus may occasionally, in the course of two or three years, descend into the cavity of the uterus, and be removed *per vaginam*. But tumors requiring removal, which do not thus become extruded, must be removed by abdominal section. There are several ways of finishing this operation. Sometimes one can close the wound in the uterus

by stitches and leave no pedicle, but simply a sutured wound, and then close the abdominal wound. Sometimes the base of the tumor and the body or neck of the uterus are compressed by a small écraseur or serre-nœud, and a long pin, passed through the stump, holds it outside the skin of the abdomen; this is called the extra-peritoneal treatment of the pedicle by Kœberlé's serre-nœud, or some modification of that instrument. Sometimes the stump is simply tied around as the pedicle of an ovarian tumor is, and is dropped back. Sometimes the stump is turned into the vagina after being ligated; this is called the intra-vaginal treatment of the stump, and is, of course, extra-peritoneal.

All the different modes of treatment depend for their fundamental success on asepsis, and on securing the vessels of the broad ligament, no matter in what way the pedicle or body or neck of the uterus is ultimately disposed of. I will not enumerate the different methods. The members of the Association are referred to the ingenious methods of operation described in the *American Journal of Obstetrics*, particularly in the contributions from Chicago during the past few years, and to the foreign journals, particularly the German ones.

The condition of most of those from whom fibroid tumors have been successfully removed by laparotomy is very comfortable. Some of them—I do not know exactly what proportion—suffer from what they call "hot flashes," by which they mean a sensation of heat rushing to their heads. This is extremely uncomfortable. In some cases it takes place every few minutes, in others at longer intervals. I do not know any way of relieving this distressing symptom. Others get extremely fat. A certain proportion, particularly those in whom the pedicle has been treated extra-peritoneally, suffer from ventral hernia. In all cases, however, in which the operation was really necessary the state of health is much improved, and the individual is very comfortable.

Sometimes the bladder is cut off by the wire écraseur, owing to its not having been sufficiently dissected off from the tumor; but in the only case of the kind occurring to me, the injury healed in a few weeks by keeping the bladder drained by means of a Sims's catheter, and the accident has caused no subsequent trouble, the bladder having remained perfectly normal since the operation, some ten years ago.

The length of an incision does not complicate an operation, provided there are no adhesions. I remember one extending from the sternum to the pubes, in which a tumor weighing fifty-three pounds was removed. The scar remained sound, and there is no hernia.

Very rarely, insanity follows the operation of removing a fibroid by laparotomy, as it sometimes does other surgical operations. Attacks of insanity that I have seen after surgical operations—such as ovariotomy, for instance—come on with normal temperature when recovery is taking place, and the insanity becomes more fixed and established as convalescence merges into health. One of my patients was an elderly person, sixty-eight years old, who recovered rapidly from ovariotomy; another was much younger, being only twenty-five years old. I have never seen insanity after hysterectomy.

I have seen tetanus twice in cases of other operators, but have never myself had an instance of it after hysterectomy. I have, however, had one case after an ovariotomy.

I invariably see that my patients that have recovered from abdominal hysterectomy are fitted with a firm abdominal supporter, and impress upon them the necessity of being careful about carrying heavy loads or straining themselves.

CATARRHAL GASTRITIS.[1]

BY HAROLD N. MOYER, M.D.,
ADJUNCT PROFESSOR OF MEDICINE IN RUSH MEDICAL COLLEGE, CHICAGO.

IN examining an old work published at the beginning of this century, giving an analysis of the admissions to the dispensary of Plymouth, England, I was struck by the nosologic entities that have disappeared from the average statistical table in the last ninety years. Among others, the general term febris has given place to a better nomenclature of the pyretic diseases. Anasarca has been succeeded by terms that reflect a better understanding of the protean conditions that underlie this symptom-group. Atrophia, convulsio and palpitatio have shared a like fate. The term dyspepsia, however, seems to occupy the same place in our nomenclature that it filled at the beginning of the century. The cause of this is to be found in the obscurity that has until recently surrounded the organic and functional disorders of the stomach. Of late, an immense gain has been made in our knowledge of the diseases of this viscus, notably in the increased precision attending the examination of the stomach-contents. It would seem as if the time had now arrived for discarding the term dyspepsia altogether as a pathologic entity and of relegating it to the limbo of broad symptom-groups occupied by such terms as heart-disease, paralysis, and deafness.

W. H. Flint, in his excellent article on the disorders of the stomach in the *Reference Handbook of the Medical Sciences*, does not use the term. It is true that so able a clinician as Dujardin-Beaumetz, as late as 1886, insisted upon retaining the designa-

[1] Read at the meeting of the American Medical Association, Section of Medicine, held in Detroit, June 7, 8, 9, and 10, 1892.

tion, though he significantly referred to the fact that his pituitous dyspepsia is called by the Germans catarrh of the stomach. Dyspepsia, too, remains a convenient term for the manufacturers of certain digestive ferments who advertise their wares as useful in dyspepsia, overlooking that by so doing they are as unphilosophic and unscientific as they would be in exploiting a remedy for the cure of blindness, paralysis, or fits.

The term dyspepsia is proper when it is used to express a condition, just as debility and nervousness are used, but the former is in no sense a diagnosis more than is the latter.

The American people are said to be a nation of dyspeptics, and by all odds the most frequent form of stomach-trouble presented by them is the simple chronic catarrhal gastritis. By this term is meant a slight degree of inflammation of the mucous lining of the organ, which in the mildest cases does not present any appreciable structural change. It is invariably accompanied by an over-production of mucus and an impairment of the digestive power, though fairly good digestion is compatible with the lighter forms of the disease.

Catarrhal gastritis is an affection frequently found associated with or complicating other disorders, both acute and chronic. On looking over my case-books for some years, I find that a diagnosis of chronic catarrhal gastritis has been made 118 times. Carefully examining these records, I find that there are only 17 cases in which the disease can be considered primary; that is to say, excluding all cases in which the disease was associated with heart and lung diseases, liver and renal disorders, rheumatism, anemia, and neurasthenia. So intimate is the relation between the condition last named and catarrhal gastritis that Bartholow regarded neurasthenia as but an effect of the digestive trouble, claiming that there was no symptom belonging to the category of neurasthenia that may not be due to purely reflex causes having their origin in the digestive tube. This view, while it is not to be accepted in its extreme application, has a certain basis of fact in that a large number of neurasthenics present more or less disturbance of the digestive tract, and very commonly the clinical picture of catarrhal gastritis. Still, the broad deduction cannot be made, because we meet with cases of neurasthenia without gastric disturbance, and again with catarrhal gastritis that has existed for years without the patient presenting any of the symptoms of neurasthenia.

Of the 17 cases in which we could exclude all complicating disorders and the grosser structural alterations, such as ulcer, tumors, and dilatation, the symptomatology was briefly as follows: In 12 cases, the tongue was heavily coated; in 3, slightly coated; and in 2 it was clean. Constipation was present in 11 cases. Pain in the epigastrium, both on pressure and after eating, was present in all cases. In 8 there was a sense of swelling or fulness in the epigastrium. Seven cases complained of nausea alone; this was usually worse after meals; the remainder had vomiting. Nine had eructations of gas. The appetite was fair in 6 cases, in 5 it was good, and in 6 it was poor.

The foregoing constitutes the clinical picture of chronic catarrhal gastritis, one of the most frequent disorders that the physician is called upon to treat. The most constant signs are the pain in the epigastrium and the nausea and vomiting, the coated tongue, constipation, and loss of appetite being by no means so regularly present.

The etiology of these cases was not so readily ascertained. The preponderance of the male sex was shown in that 13 of the 17 cases were men. The chief cause was the abuse of alcoholics, both in fermented and distilled liquors. The practice of dram-taking just before meals seemed to excercise an especially deleterious influence. There was a history of excessive use of tobacco in several instances, but no case was uncomplicated by the liquor-habit. The ingestion of iced liquids, either before or with meals, seemed to be an exciting cause in four cases. Two of these patients used large quantities of tea. In more than half of the cases the etiology was mixed, and in many no definite cause could be ascertained. These latter, however, all belonged to the dispensary patients, and it is probable that poor and improperly prepared food had much to do with the condition. In no single instance could the disease be traced to pre-existing acute or subacute gastritis. The disorder invariably came on gradually, with periods of amelioration, to be followed by relapses, the symptoms gradually becoming worse until the patients consulted a physician. The duration of the disease varied from several months to many years.

The necessity for washing out the stomach in these catarrhal inflammations has been dinned into our ears for some years. Scarcely a recent text-book can be consulted that does not recommend lavage of the stomach as the remedy *par excellence* in catarrhal gastritis. I have no issue to take with this statement; lavage is one of the best means at our command; but notwithstanding continued reiteration, the method does not seem to have become at all popular or to have met with extended application. The reason is not far to seek. The procedure requires a somewhat cumbersome apparatus and the necessity of teaching the patient how to use it. I do not know what the experience of others has been, but my own successes in this direction have not been brilliant. Occasionally a patient can be taught to use the tube, and if he will persist he

soon comes to like the treatment. As a rule, patients object when the subject is first mentioned, and if they try the method the generally unpleasant effects of the first one or two introductions is sufficient to send them in search of a physician who employs a less disagreeable treatment. The result has been that the profession has generally adhered to the old-time prescription of bismuth with pepsin, and sometimes a bitter tonic. If any directions are given regarding diet, it is generally no more specific than that he is "to be careful with his diet," or "to eat light food." It is needless to say that these methods are as unphysiologic and unscientific as they are unsuccessful. Patients in this way drift about from one physician to another, until it is not an uncommon experience for them to enter one's office, and after detailing their sufferings, tell you that you need not give them pepsin, bismuth, syrup of the hypophosphites, or beef, wine and iron, as they have had all these.

In catarrhal gastritis the stomach secretes an excessive quantity of mucus. As soon as the food is ingested it is at once coated and prevented from coming in contact with the stomach-wall. The result is that the stomach is not supplied with its normal stimulus, and both the secretion and movements of the organ are lessened. What secretion there is cannot readily reach the food; in consequence, in the absence of the antiseptic power of the gastric juice, the food ferments, gases are formed, and vomiting takes place. The prolonged retention of food and the irritation react to increase the inflammation and congestion of the organ. This morbid cycle, once set up, perpetuates itself with ever-increasing intensity.

The plan employed in treating the seventeen cases that form the basis of this paper consisted in the administration of hot alkaline water before each meal. Sodium bicarbonate is added to the water in the proportion of ten grains to the pint. Of this solution eight, twelve, or even sixteen ounces, according to the severity of the case, are administered at least twenty minutes before each meal. The water should be as hot as can comfortably be borne, and should be taken slowly. By this means the stomach is effectually cleared of its contained mucus, and is prepared for the reception of food. This should consist of a test-meal of from four to six ounces of steak, preferably broiled, with from two to four ounces of bread, thinly buttered. From this starting-point the diet should be increased or decreased as the patient does or does not suffer from nausea or vomiting. The central idea of the diet in these cases is to restrict it largely to proteids, such as lean meats, oysters, and eggs, together with a small quantity of bread. All starches and fats should be excluded, excepting the small quantity contained in the thinly buttered bread. This is a matter of importance because of the readiness with which starches and fats undergo decomposition when gastric digestion is delayed. When the quantity of food that the incompetent organ will digest without leaving a residuum for fermentation has been ascertained, it should be held for a few days at that point and then gradually increased. As the inflammatory condition subsides, the organ gains strength, and the diet may be increased and made to include a greater variety of food. It is doubtful if anyone who has ever had a chronic gastritis should be allowed to eat mince-pies, tarts, plum-puddings, or other culinary abominations. Bismuth, cerium oxalate, nux vomica, and the bitter tonics are useful adjuvants in treatment.

I do not think that pepsin is of any value in the treatment of chronic catarrhal gastritis. I do not wish to be understood as decrying the value of pepsin in certain stomach disorders, notably those attended by atrophy of the gastric tubules, or other structural alterations. Pepsin is also useful in the cases of catarrhal gastritis dependent upon anemia, nephritis, and other disorders in which the primary trouble is due to failure of gastric secretion from a deficient or poor blood-supply. In these cases the agent may prove invaluable, but, in my judgment, the dose usually employed is much too small. It is in the uncomplicated inflammations that I regard pepsin as valueless; the indigestion is dependent on an entirely different set of conditions.

Relapses are exceedingly common; in fact, they occurred in every one of my cases. They are to be met by a return to the treatment, if it has been suspended, or to a stricter and lessened quantity of food. In the course of the treatment the relapses will occur less frequently; they will be less severe, and will yield more readily to the remedies employed.

The results in the seventeen cases were excellent: eight of them recovered, remaining well at least six months after suspending treatment. Of the remaining nine cases, all were improved, and some of them could be considered recovered, as they passed from under observation completely relieved, but I had no opportunity of learning their condition some months after suspending treatment. In no case was the treatment persisted in for some weeks without marked improvement being noted.

In conclusion, allow me to say that the method of treatment here outlined is of little or no value in cases of tumor, stricture, atrophy of the gastric tubules, or other gross alteration in the structure of the stomach, or when there is marked dilatation. In cases complicated by heart, lung, kidney, or liver diseases, or by anemia and neurasthenia, the method may be a useful adjunct, but we can hardly expect

a cure. It is claimed that it meets the indications in simple catarrhal gastritis quite as well as lavage, that it is much less trying to the patient, that it is adapted to the poorer classes and to dispensary patients, who in many instances are unable to afford even the small expense of a stomach-tube.

ORIGINAL ADDRESSES.

SURGERY OF THE GALL-BLADDER AND DUCTS.

BY J. McFADDEN GASTON, M.D.,
OF ATLANTA, GA.

Abridged Address of the Chairman of the Section of Surgery and Anatomy of the American Medical Association, delivered at Detroit, June 7, 1892.

IN regard to the procedures heretofore adopted, I would refer those who may be interested to my article in *Gaillard's Journal*, October, 1884, also to the reports of my experimental work in the *Atlanta Medical and Surgical Journal* for September and October, 1884, and September and November, 1885. A complete *résumé* of this subject was made in my contributions to the second volume of the *Reference Handbook*, in 1886, under the headings of Cholecystectomy, Cholecystotomy, and Duodeno-cholecystostomy. My paper on "The Surgical Relations of the Gall-bladder to Obstruction of the Ducts," will be found in the *Transactions of the Medical Association of Georgia* for 1886. A contribution to the British Medical Association at Brighton, in 1886, "On the Practicability of Establishing an Artificial Fistulous Opening, in the Human Subject, between the Gall-bladder and the Duodenum," appeared in the *British Medical Journal*. These publications included the data presented by others up to the time of their presentation; and have doubtless had their share of influence upon the subsequent treatment of this class of cases.

The increasing interest exhibited by surgeons in the serious consequences resulting from any obstruction to the flow of bile from the liver, has been characterized by greater activity in affording surgical relief for these troubles. Various operative measures touching the gall-bladder and ducts, with crushing of gall-stones, have brought about a revolution not only in the theoretic views of surgeons, but in their surgical appliances. A new era has dawned upon gall-bladder surgery, and old things are passing away, to be consigned to the sea of oblivion.

While the operation of natural cholecystotomy has been done, in a large number of cases, by different surgeons, there has been no material improvement in its technique or in its final benefit to the patient.

The organic changes to which cholecystectomy is usually thought to be best adapted have not been encountered so often as to require this measure in many cases; yet the good results in a large proportion of the operations reported warrant its adoption under certain conditions, and I have suggested that in excising the gall-bladder its upper wall should be left adherent to the liver.

Incision and suture of the wall of the common bile-duct for the removal of gall-stones have been practised in twelve cases, with only one fatal result from the operation. Three of the cases have been operated on by Courvoisier, and one by each of the following named: Kummell, Heusner, Kuster, Rehn, Braun, Frank, Hochenegg, Marcy, and Vander Veer.

The development of the possibilities of benefit from the anastomosis of the gall-bladder and the common bile-duct with the duodenum and other divisions of the intestinal canal has lately occupied the earnest attention of surgeons. When the natural outlet for the bile becomes obstructed, it is recognized as proper to effect an artificial passage for it into the intestine. A new departure in operative measures consists in connecting the walls of the common duct with the duodenum, as was done in a case reported in the *Deutsche medicinische Wochenschrift*, September 3, 1891.

A woman, forty years old, suffered from the usual concomitants of biliary obstruction. After the abdomen was opened, the cystic duct was mistaken for the common duct, and the latter for the duodenum. A stone found in the first was pressed into the distended common duct, and the passage was supposed to be free; but in a subsequent operation, a stone was found in the cystic duct and a second at the portal channel; the second stone was crushed. The common duct filled immediately with bile, and in order to provide an outlet it became necessary to connect the walls of the duct and of the duodenum, by incising each and bringing them together with stitches. In doing this, some bile necessarily flowed into the wound, but no serious disturbance followed. Three months afterward the patient had recovered from all trouble, and it is to be inferred that the communication between the common duct and the duodenum was maintained.

A modification of cholecystotomy, proposed by Wölfler, has been adopted in a few cases, in which all abnormal accumulations are removed from the sac, and the ducts are freed of any concretions, with a fair prospect of the full restoration of their functions. The incision in the wall of the gall-bladder is closed, and then attached by sutures to the parietal incision. It is provided in this operation that when the union of the incised wall of the gall-bladder shall be completed, a separation of the attachment to the external parietes shall be effected, so as to allow the gall-bladder to be free. This process is based upon a doubt as to the efficiency of suturing the tissues of the sac; and in case of any yielding of the stitches, to favor the escape of the bile through the parietal wound, instead of into the peritoneum. While the presence of freshly produced bile is not proved to be productive of serious results, this procedure implies an abundance of caution against the contingency of failure in suturing the sac.

In the ordinary process of attaching the incised wall of the gall-bladder to an opening in the abdomen, styled natural cholecystotomy, with a view of providing an outlet for the bile, there is no provision for utilizing this discharge from the liver. When the ducts are patulous, leading into the gall-bladder and into the duodenum, the process of ideal cholecystotomy by emptying the contents of the gall-bladder and closing the incision of the walls, dropping this viscus into the abdomen, has been attended with satisfactory results, and a successful case has recently been reported by Hardon.

It would appear, however, that all cases of obstruc-

tion of the cystic and common ducts by gall-stones, call for their dislodgement by one or another procedure, to afford an outlet for the bile; and that the attachment of the incision in the gall-bladder to the opening in the wall of the abdomen, leading to a discharge of the bile externally, should be regarded as a mere temporary recourse. In the event of failure to effect an outlet for the bile through the common duct, cholecystenterostomy is clearly indicated.

As to the portion of the intestine that should be selected for the attachment of the gall-bladder or the ductus choledochus, we have a definite guide in the entrance of the bile naturally into the duodenum; and the nearer to this point that an anastomosis can be effected, the better the result that may be expected. The relations of the duodenum and jejunum to the gall-bladder are ordinarily such as to facilitate their union, and I have given the preference to the duodenum from physiologic considerations as well as from surgical convenience, while objecting to the colon.

It is, of course, presumed that there is such an occlusion of the common bile-duct as to prove irremediable by other means, before proceeding with an operation to effect an outlet for the bile by uniting the gall-bladder with the intestinal canal. A misunderstanding of this condition has led to misapprehension of the end to be attained by duodeno-cholecystostomy or cholecystenterostomy, and, once for all, let me say that it is only warranted by occlusion of the common duct. While each of the several operations may be indicated in special cases, the present outlook of anastomotic procedures for conveying the bile from the liver into the intestinal canal in case of obstruction of the common duct is entitled to precedence in gall-bladder surgery.

All of our resources being exhausted without relief to the impediment for the discharge of bile through the ductus choledochus, and finding the integrity of the gall-bladder favorable for its attachment to some portion of the intestine, we may rest assured that we shall be able to effect an opening from the former into the latter by which the bile shall subserve its legitimate purpose in the animal economy.

The various procedures adopted by Golzi, Page, and myself in our experiments upon dogs were undertaken with a view to guide others in the performance of operations upon the human being. This work must hold a place similar to that of pioneers who have gone forth to blaze out the paths in an unexplored region and have set up danger-signals to caution the unwary traveller that may come after them in the search for a route that shall lead to the goal of his expectations. Some quagmires and quicksands were encountered by us that may be avoided by others. All must allow that the fruit of our experience has thrown much light upon the intestinal labyrinth in which we groped without a guide to direct us at that period.

My efforts were directed at the outset mainly to the establishment of a fistulous communication between the gall-bladder and the duodenum by means of an elastic ligature passed through their approximated walls. This was surrounded with a circular or an oval continuous suture of catgut, so as to effect the immediate adhesion of the serous surfaces; but it was subsequently found that a single stitch of silk thread united the surfaces and ultimately cut its way through the two approximated walls so as to effect a communication between the gall-bladder and the duodenum.

The difficulties encountered in ligating the common bile-duct subsequently were the greatest obstacles to the final success of this operation, and would not be encountered in case of preëxisting occlusion, which is the condition demanding operation in the human subject.

These and other experiments, undertaken upon twenty-one dogs, are illustrated in the cuts accompanying my paper laid before the British Medical Association. It may be stated, however, that my conception of the procedures indicated were not limited to the means employed in these experiments, and it was distinctly set forth that some other process might be found preferable, and it rests with surgeons to adopt that which proves best.

A number of operations have been referred to by Ross, as undertaken by different surgeons, with a view of securing the results aimed at; and I cannot perform a more profitable service to the profession than to present some of the details, gathered from various sources.

To Nussbaum is attributed the first suggestion of relieving the occlusion of the common bile-duct by conveying the bile into the intestinal canal through artificial openings in the adherent walls of the gall-bladder and the intestine; but the credit of having first accomplished this result upon the human being is undoubtedly due to Von Winiwarter; and it affords me the greatest satisfaction to award him the honor of priority in the execution of cholecystenterostomy.

We are informed that between the 20th of July, 1880, and the 14th of November, 1881, he treated for sixteen months a man, aged thirty-four years, who suffered from obstruction of the common bile-duct, and who was subjected to six different operations for the formation of a fistula between the gall-bladder and the colon.

All kinds of difficulties thwarted this undertaking, but it is claimed that the surgeon eventually succeeded in attaching the gall-bladder to a coil of the small intestine, and effecting a fistulous communication, by which the bile escaped into the intestinal canal, thus obviating the inconveniences of an external outlet.

After a lapse of six years, during which the various experiments on dogs by Golzi, Page, and myself, were performed, Monastyrski united the gall-bladder with the jejunum, on the 4th of June, 1887. He incised the abdominal wall, punctured the gall-bladder, incised its walls and those of the jejunum, and sutured the edges with catgut. A fistulous communication was secured two meters below the duodenum, but death ensued ultimately from carcinoma of the head of the pancreas, as verified by the autopsy.

The operation of Kappeler came next in the order of time, being done on the 6th of July, 1887, by uniting the gall-bladder with the ileum by Wölfler's suture. The patient progressed favorably for a time, and returned to work, but eventually died on September 9, 1888, fifteen months after the operation. The autopsy showed that a fistula had been established about eight feet from the ileocecal valve, and that its intestinal orifice was provided with a valve that allowed the contents of the gall-bladder to pass into the intestine, but prevented the passage of intestinal contents into the gall-bladder. Doubtless a similar provision exists in all such cases.

In the year following the operation of Kappeler, Fritsche established a fistulous opening from the gall-bladder into the jejunum, three meters below the pylorus. At the post-mortem examination a carcinoma of the size of a walnut was found at the mouth of the common bile-duct. Socin and Bardenheuer each attached the gall-bladder to a loop of the small intestine. The case of the latter died in the fourth week, and no fistula was found. It is said that the operation was done with elastic ligatures.

On March 2, 1889, Robson operated upon a patient that had previously been subjected to cholecystotomy, when the ducts were found, and the gall-bladder was attached to the abdominal wall by firm adhesions. The common duct subsequently becoming occluded, an incision was made through the scar from the former operation, in the semilunar line, and it was found that the attachment of the gall-bladder could only be effected with the colon. Both were incised, and united with chromic catgut in two rows. The former external fistula was closed by suture, and a drainage-tube was inserted in the wound. After one day, bile came out of the drainage-tube, and also fecal matter from the intestinal wound. In spite of this complication, a speedy recovery, with the appearance of bilious matter in the feces, is reported.

On July 13, 1889, Terrier performed an operation for the relief of occlusion of the common duct. An incision was made in the median line above the navel. The gall-bladder was punctured and the contents evacuated. Upon incising its walls and exploring its cavity no stones were found and the cystic duct was open. In the oblong enlargement of the common duct was impacted a gall-stone which could not be removed. After attaching the gall-bladder to the duodenum by a circular or oblong row of catgut sutures and before tying the last stitches, the walls of both were incised and a rubber drainage-tube was introduced, so as to pass from the cavity of the gall-bladder into the duodenum. The fundus of the gall-bladder was sutured to the lower angle of the external incision, which was then closed by catgut sutures. There was fever until August 1st, but the itching and jaundice gradually disappeared. The drainage-tube passed off with the evacuations nine days after the operation, and the stools gave evidence of the presence of bile. The external wound healed by first intention. The patient was dismissed on August 10th in ordinary health.

This patient died in the spring of 1890 from influenza and no gall-stone was found in the common bile-duct.

Courvoisier, in like manner with Robson, performed the operation of natural cholecystotomy upon a patient, without obtaining a satisfactory result. After the lapse of a year, complications arose that demanded the performance of cholecystenterostomy, and this was done on the 28th of March, 1890. An incision was made through the abdominal wall, below the ribs, along the border of the liver. The gall-bladder was detached from the abdominal wall, and after incising the sac, the gall-stone was removed from the common duct and others scooped from the hepatic ducts.

An incision into the lower surface of the gall-bladder was united to the colon by an oval row of catgut sutures, and before putting in the last stitches the wall of the colon was incised. The fistulous parts of the gall-bladder were cut away and the edges stitched. Two drainage-tubes were inserted and the external wound was closed around them. There was no fever after April 2d. Bile was found on the dressings, but its source was not determined. Bile appeared in the stools on the 6th of April, and on the 8th the drainage-tubes were removed and the external wound was sutured. On the 15th of April the patient was free from jaundice and got up feeling very well. The case was dismissed about the middle of May, and in the middle of July her condition was excellent. There was no more colic or jaundice.

Courvoisier thus sums up the result of these seven cases. One case operated upon died, as a consequence of a complication which should not be charged to the method. All the others recovered from the operations, but in four of the cases the carcinomatous condition of the pancreas caused death at a later period. A definite final cure is claimed only in the cases of Robson and Courvoisier, in which, it will be remembered, the gall-bladder was attached to the colon, not by choice but from necessity.

The practicability of effecting an outlet from the gall-bladder into the intestinal canal can no longer be doubted, and in the view of Courvoisier it stands more and more securely as the details from trustworthy sources become more widely disseminated.

The indications for the operation are formulated by him as follows:

(*a*) When biliary fistulæ are difficult of removal, whether traumatic, ulcerative, or operative.

(*b*) In permanent obstruction of the common bile-duct (except in cases of gall-stones).

(*c*) In traumatic and ulcerative communications between the common duct and the abdominal wall.

Operation is contra-indicated:

1. When the patients have grown very feeble, in which cases provisional cholecystostomy might be performed.

2. When the common duct is obstructed by gall-stones, in which cases cholelithotomy, with stitching or lithotripsy, is indicated.

A case of cholecystenterostomy has been reported by Helferich, in the *Deutsche medicinische Wochenschrift*, February 25, 1892, for the details of which I am indebted to Dr. P. J. Rosenheim, of New York.

The patient, a man aged thirty-nine, had suffered periodically from pains in the stomach since 1885, and developed jaundice in April, 1891. During the following month he had attacks of biliary colic, recurring every fortnight, the jaundice being more marked after every attack. It was thought that the common duct was obstructed by calculi, and an operation for their removal was undertaken in November. An incision was made midway between the lower border of the ribs and the border of the enlarged liver, extending vertically in the linea alba to the ensiform cartilage. After the liver had been retracted, the gall-bladder came into view; it contained no calculi, but an examination disclosed a number of calculi in the common bile-duct, which it was found impracticable to remove. An opening was therefore made in the gall-bladder and another in the first part of the jejunum, and a communication was established between these viscera by suturing the

corresponding margins of the apertures. The fistula thus formed was of the caliber of a lead-pencil. The patient made a rapid recovery, the symptoms of jaundice having disappeared. During the following January he experienced two light attacks of fever, without any jaundice, attributed to calculi in the common bile-duct. As a means of affording palliation of his sufferings, the operation was a success.

Chavasse has reported in the *Lancet* an interesting case in which an anastomosis between the gall-bladder and the colon was effected by a process differing materially from the previous operations. A man, forty-eight years old, had undergone chelocystotomy for the relief of jaundice, dependent upon biliary obstruction by calculi, which was followed by the persistence of a biliary fistula. Other measures failing, with the aid of Senn's bone-plates a communication was established between the gall-bladder and the colon at its hepatic flexure. At first, bile and fecal matter were discharged through the abdominal wound, but ultimately this closed, the stools were passed naturally, and the general condition of the patient was much improved.

Korte also reports a successful case of the union of the gall-bladder with the duodenum, after the manner of Terrier, thus affording two favorable results from duodeno-cholecystotomy.

So far as the operations are to be considered, those of Kappeler and Terrier were successes, and being added to the other six cases with finally good results, we have eight cures of twelve in which the operation of cholecyst-enterostomy has been successfully performed, being a mortality of only 25 per cent. from the operations.

This encourages the expectations with improved methods of obtaining a satisfactory solution of the problem of relief for occlusion of the common bile-duct. While other means may be employed for correcting temporary obstructions of the ducts, the great desideratum in occlusion of the common duct is to provide an artificial opening from the gall-bladder or duct into the duodenum or the adjacent portion of the intestinal canal.

SOME MOOTED POINTS IN OBSTETRICS AND GYNECOLOGY.[1]

BY E. E. MONTGOMERY, M.D.,
OF PHILADELPHIA.

GENTLEMEN: In considering a subject for an address to this body, I felt I could more profitably employ your time by discussing some of the mooted points in obstetrics and gynecology, than by the presentation of a paper upon any special subject.

It is true that some of the subjects I have chosen may seem trite, but it cannot be said that they are unimportant, and unworthy of careful consideration.

It is with hesitancy that I consider some, for the reason that they will be more extensively and ably discussed in papers that are listed for your appreciation.

Cæsarean Section versus Craniotomy.—Under cruder methods of procedure a comparatively low valuation was placed upon intra-uterine life. We need but to review the statistics of the earlier British obstetricians to see in how much larger ratio the life of the child was sacrificed than resort was made to the use of the forceps. As this instrument was more frequently used, the number of instances in which it was found necessary to destroy the child was greatly diminished. With the knowledge secured through the practice of antiseptic measures, the term of human life has been lengthened and the importance of the unborn individual has obtained a higher appreciation. The obstetrician more and more recognizes that in every case of labor there are two individuals to be considered, each of whom must be afforded a chance for life.

In view of the safety of the induction of premature labor, of the decreased mortality of the modified Cæsarean and Porro operations, it has become a serious question in the minds of many of our best practitioners, whether the living child should ever be subjected to embryotomy.

It is a source of continual opprobrium to our profession that we must sacrifice life to save it. With the reduced mortality of the Cæsarean procedure experienced by Zweifel (one in eighteen), it no longer seems just that the life of one of the interested individuals should be destroyed. The responsibility of parentage, the obligation to the unborn, both of physician and patient, should have a higher standard of appreciation. We would urge that craniotomy in obstructions of the pelvis be elected only when, first, the child is certainly dead and its delivery unmutilated would endanger the vitality of the maternal tissues; second, after repeated mechanical efforts to deliver the child still living, and the physical signs demonstrating that the child is too feeble to long survive its birth; the maternal peril should not be increased, or comfort lessened, when it is evident that the child has no chance of surviving; third, the existence of hydrocephalus or other irremediable disease in the fetus.

The choice between the Cæsarean and Porro operations has been much discussed. The advocates of the latter procedure claim that it lessens the danger, by the removal of the large absorbing surface of the uterine body, obviates the escape into the abdomen of fluid from the uterus, and saves the patient from subsequent recurrence of pregnancy. Its opponents reply that an operation properly performed, should leave the cavity in as good condition as after an ordinary labor; the uterus, carefully sutured, quickly unites, rendering leakage into the abdomen extremely improbable.

The prevention of subsequent pregnancy is not always desirable, even in rhachitic patients, as it has been recognized that their defects have no special influence upon the health of their offspring.

The danger in secondary Cæsarean operations is greatly lessened.

The statistics collected by Harris have demonstrated that this operation has not been attended with results as favorable as those of the modified Cæsarean. It is indicated in the presence of large fibroid growths, or if the patient has been long in labor, and the uterus has become bruised and partially devitalized, or in the presence of beginning sepsis.

Placenta Previa.—There is probably no condition that has given greater anxiety or has been the subject of

[1] The President's Address, read at the opening of the meeting of the Section of Obstetrics and Diseases of Women, American Medical Association, Detroit, June 7, 1892.

more varied discussion than the attachment of the placenta in the lower segment of the uterus. When we consider the danger to the individual arising from the progress of such a condition, it seems unwise to permit her to be subjected to it, if there be any possible means to avoid it. If it has been demonstrated that the placenta occupies the position known as centralis, what possible advantage can be urged in permitting the patient to go on almost to full term, with a possibility of recurring hemorrhages, any one of which may prove fatal before a physician can be secured. In such cases it is very rare for the child to be delivered alive, and consequently, with the slight possibility of its being saved, the life of the woman should not be imperilled.

The better plan of treatment would seem to be that urged by Wyder. Secure dilatation of the uterus sufficient to permit of version by the Braxton-Hicks method, then drag the limbs into the cervix; these will act as a natural tampon and prevent further hemorrhage.

I was called some time ago to see a woman—the wife of a physician—in Lock Haven, Pa. I arrived at 8 A.M., and found that she had been suffering from repeated attacks of hemorrhage. Placenta previa had been suspected; the uterus was dilated sufficiently to permit the introduction of one finger; this was followed by a second, forcibly dilating the uterus until the two fingers were in its cavity, then the membranes were ruptured, and by external manipulation, one leg of the child was brought in contact with the internal fingers, and drawn into the cervix. By moderate traction the uterus was dilated, and the fetus delivered; the placenta was removed, uterine contractions secured, and the vagina and uterus irrigated, the entire maneuver being completed in less than three hours. This patient had previously had two or three hemorrhages, which had led to fears of her inability to recover therefrom. She was exceedingly weak and debilitated. The child was stillborn; the mother recovered without any untoward symptoms.

According to Wyder, the maternal mortality under the old plan of treatment reached from 30 to 40 per cent., while the statistics of the clinics of Schröder and Gusserow, in which the plan of treatment just considered was followed, the percentage of mortality was from 6 to 7 per cent. The infantile mortality under the old methods was from 50 to 70 per cent. Under the new it is but slightly more, being but from 70 to 80 per cent., and this mortality is of course compensated by the greatly reduced maternal loss. In addition to the advantage of relieving the patient and physician of every anxiety, it also decreases the danger to the patient from sepsis during the subsequent convalescence.

Sepsis.—The importance of early treatment of septic conditions cannot be too highly appreciated. When we consider the rapidity with which diseased conditions extend from the uterine mucous membrane to that of the tubes, and along the lymphatics, subsequently involving the ovaries and peritoneum, we cannot urge too strongly the necessity of prompt measures to arrest the progress of the disease while still within the uterus. Infection of the uterine cavity leads to rapid development of inflammatory changes in the mucous membrane and to arrest of normal processes. Multiplication of germs in the mucosa and repeated absorption of their products into the system, produce all the symptoms of septicemia. The usual course when elevation of temperature occurs is to proceed with frequent intra-uterine irrigation, thus endeavoring to obviate the unpleasant effects of the poison. The difficulty, however, in accomplishing this, or in rendering it thoroughly serviceable, is that we have the membrane of the uterus coated with considerable débris, which is only superficially affected by the germicidal irrigation. Consequently we would urge the necessity, not only of irrigation, but of thorough curetting of the cavity, scraping away the broken-down and infected tissue, either with the blunt curette, or with what is a still better instrument, the finger.

Having removed and loosened this tissue as thoroughly as possible, the intra-uterine syringe should be used, taking proper precautions to secure a free flow of the fluid from the organ. The irrigation may be practised by the use of a solution of acid sublimate or of hydrogen dioxide. When the former agent is used, it should be followed by irrigation with sterilized water, so that the superfluous material that might be absorbed and poison the patient, will be washed away.

The thick, flabby walls of the uterus, lying in contact with each other, lead to blocking up of the uterine secretion in the cavity of the organ, and thus promote the tendency to putrefactive changes. To avoid this, drainage should be secured. It may be done by introducing a rope of iodoform-gauze to the fundus of the uterus. This serves an excellent purpose: first, in keeping the walls apart; second, it acts as a drain, through its capillary action; and third, by its presence, as a foreign body, it stimulates the processes of involution. When the vagina and uterus have been thoroughly cleansed and prepared for its introduction, the twist of gauze may be left for from forty-eight to seventy-two hours. Its removal should be followed by careful irrigation and the reintroduction of gauze. In this way the size of the uterus may, in a short time, be reduced to the normal.

The serious effect of extension of inflammation from the uterus must impress on the obstetrician the great importance of early treatment. In several instances it has been my experience to have to consider the necessity of operative interference to save the life of the patient. In one instance repeated attacks of chills and fever, occurring weeks after the uterus had been curetted and irrigated, led to opening of the abdomen and removal of the ovaries. In one of these, a teaspoonful of stinking, greenish-yellow pus was found. The operation was followed by rapid subsidence of all inflammatory changes, and the recovery of the patient.

In another instance a mass was found in the left side of the uterus that proved to be a large pus-sac, after the removal of which the patient recovered.

A case was recently seen in the practice of Dr. Parish, of Philadelphia, in which an abscess had extended into the wall of the uterus. In this patient, one side of the uterus was cut away nearly to the cavity of the organ, and the walls sutured, bringing the peritoneum over the denuded surface, and the patient fully recovered. In the presence of such possible results, the patient should not be permitted to remain without attacking the disease in its original site of development.

Endometritis.—In acute or chronic inflammation of the non-pregnant uterus, it seems just as important that,

whenever possible, diseased conditions should be arrested while confined to the uterine cavity, and their extension to inflammation of the tubes prevented. The treatment in such diseased conditions becomes a serious question. How can we best remedy them, and what plan of procedure is least likely to be attended with inflammatory extension? When we find the uterine canal abraded of its ciliated columnar epithelium by the catarrhal processes, its glands stimulated to greater activity, and filled with viscid secretion, the mucous membrane of the uterus oftentimes covered with papillary masses, resembling polypi, the surface of the entire canal much resembling that of an ordinary sinus—it seems but prudent that, as early as possible, every precaution should be taken to correct the condition. Here, as in every other sinus, it is important to secure thorough and prompt drainage. After thorough aseptic precautions the proper plan of procedure would be the dilatation of the uterus, curetting of its cavity, washing it out with a disinfectant solution, and then the application of some means to secure drainage. This may be done either by the method of Polk, or that of Wylie and Boldt.

Polk packs the cavity of the uterus with iodoform-gauze, trusting to its influence on the mucous membrane to bring about more rapid activity of the uterine circulation, and consequent diminution in the size of the organ. The grooved stem-pessaries of Wylie and Boldt also increase the activity of the circulation, and promote drainage. These instruments may be worn for some length of time, and under their influence the uterus will undergo rapid involution.

Trendelenburg Posture.—In the various operations upon the pelvic organs, the majority of operators have followed the lead of the pioneers in this field, and placed the patient in the horizontal position. This posture of the patient has, however, been attended with a number of disadvantages: first, the difficulty of illuminating the pelvis, and being able to see into the deeper cavity, and thus secure bleeding-points. If the operator, having in many cases to depend upon touch to determine the condition of the broad ligament, should through any misfortune let the ligature slip, allowing a vessel to spurt, profuse hemorrhage can take place before he may be able to determine its origin. Second, the intestines, retained with difficulty, are very likely to be pushed out of the wound, and still further obscure the pelvic cavity. The posture known as the Trendelenburg, and which has been ably advocated in this country by Dr. Krug, of New York, aims to place the patient in a position in which the lower part of the pelvis is elevated at an angle of from 45 to 60 degrees. This done in front of a window, permits the light to fall directly into the pelvis, when the wound is held open, and at the same time causes the viscera to fall upward toward the diaphragm, preventing them from obscuring the vision. In this posture, the physician and attendants are enabled to look directly into the pelvis, and see the bladder and uterus, the appendages, the existence or non-existence of adhesions, and the relations of the pelvic and abdominal viscera. If coils of intestines are adherent, these points are seen, the enucleation can be accomplished under the eye, and the extent of the involvement can readily be recognized. If bleeding occurs during the procedure, it can also be seen, and the bleeding-points promptly secured. It has been objected to the plan, that there is greater danger of soiling the upper portion of the abdominal cavity with pus, but if the operator is careful in placing sponges around the pus-cavity, this can be entirely prevented. Indeed, the intestines can be pushed upward covered with sponges in such a way that there is no possibility of any soiling of the peritoneal cavity above the abscess itself.

The cavity thus being freed from contact with pus and blood, the field of operation directly under the view, there is not the same necessity for abdominal irrigation that there would be when an abscess-cavity is broken up, and pus flows upon the loops of the intestines and over the entire pelvis and its contents. The position is one that is of great advantage in every operation involving the removal of the uterine appendages. It is almost indispensable in those operations in which the entire uterus is removed through the abdomen.

Hysterectomy versus Supra-vaginal Hysterectomy for Fibroid Growths. — The extra-peritoneal treatment of the pedicle in the removal of fibroid tumors of the uterus has long been recognized as the most effective method of controlling hemorrhage from the stump. On account of the elastic character of the uterine tissue the majority of operators have hesitated to trust the ligature to control hemorrhage in these cases. The extra-peritoneal treatment of the stump, however, is attended with many disadvantages. Not infrequently the stump is necessarily a short one; the traction upon the vagina and the pressure against the bladder are marked and distressing; the size of the stump, filling up a large portion of the lower angle of the wound, necessarily produces a weakened ventrum; and the pressure of the pins upon the abdominal surfaces, resulting from the traction of the stump, not infrequently leads to ulceration. The retraction of the stump following removal of the serre-nœud produces a large cavity that must heal by granulation, thus delaying the convalescence of the patient. For this reason there has been a constant effort upon the part of the profession to avoid the necessity of extra-peritoneal treatment of the stump.

As we have already mentioned, the mortality of intra-peritoneal treatment has been disproportionately large. When we consider that the stump is of no special value, and can be so easily removed, it seems singular that it has been permitted to remain so long. To accomplish its removal, however, the better plan of procedure is that instituted by Krug, which consists in throwing about the stump an elastic ligature, or temporarily applying a clamp to the cervix, cutting off the tumor, and then opening into the vagina posteriorly, followed by the separation of the bladder anteriorly, until the vagina is reached, and the broad ligament ligated on each side, in sections.

To perform this portion of the operation, the Trendelenburg posture is of very great advantage. Krug ligates with silk, leaves his ligatures long and draws them out through the vagina, in this way inverting the edges. He depends upon drainage secured by packing the vagina and lower part of the abdomen from above with iodoform-gauze. This, at the end of a week, is withdrawn through the vagina. From this part of his procedure, however, I am inclined to dissent, preferring to ligate the broad ligaments with catgut ligatures, which

are to be cut short, and then following the procedure suggested by Reed—suture the peritoneum over the upper part of the vagina, shutting it off from the peritoneal cavity.

In those cases in which the peritoneum cannot be entirely brought together, and there has been considerable denudation, the vaginal opening may be closed and drainage accomplished by the glass tube or the gauze twist brought out at the lower angle of the wound. The advantage of thus leaving the stump is that the wound will close in a short time, and we do not have the depressed granulating wound, to delay the subsequent convalescence and to leave for years a weakened ventrum.

Sacral Resection.—Kraske, in 1885, pointed out the accessibility of the middle part of the rectum by a posterior incision, removing the coccyx and part of the lower two segments of the sacrum. Hochenegg and Herzfeld have demonstrated the application of this procedure to some of the gynecologic operations. When we consider the position of the uterus in the pelvis, we can but recognize that the shortest distance to it is directly through the lower extremity of the sacrum. The application of this operation to gynecologic work is necessarily limited, but it is none the less of interest as a method of procedure in some cases that offer complications by the ordinary plans of operation.

I have reported two cases in which this operation has been performed for the removal of the uterus. In one the condition was complicated by carcinoma of the middle part of the rectum, involving the upper part of the posterior wall of the vagina and the cervix. In the operation, about three inches of the rectum, the upper part of the posterior wall of the vagina, the uterus, and the ovaries were removed. The patient recovered from the operation, but succumbed six months later from a return of the disease.

The second case occurred in a nulliparous woman, who had epithelioma of the cervix, complicated by a previous inflammation of the tubes and ovaries that had bound them down to the uterus posteriorly. It is recognized that ordinary vaginal hysterectomy, with an undilated vagina, with the uterus, ovaries, and tubes bound down by adhesions, would be an exceedingly difficult procedure.

In considering the case, it was determined to perform the operation by sacral resection in preference to opening the abdomen from above. The result was exceedingly gratifying; the tubes were easily reached, readily ligated, the vessels could be seen, the relation of the ureters to the uterus determined, and the organs accordingly very readily avoided. The method of performing the operation has been so thoroughly described in recent publications that it does not seem necessary to occupy your time further in its description.

CLINICAL MEMORANDUM.

A METHOD OF INFECTION, TREATMENT, AND PROPHYLAXIS OF PURULENT OPHTHALMIA.[1]

BY GEORGE M. GOULD, A.M., M.D.,
OPHTHALMOLOGIST TO THE PHILADELPHIA HOSPITAL, PHILADELPHIA.

I. AS TO THE DISEASE.

ALMOST every case of purulent conjunctivitis indelibly impresses upon the mind of the surgeon two striking and puzzling facts:

1. The obstinacy of the disease, its stubborn persistence and unaccountable resistance to the most thorough and most scientific methods of treatment. We cleanse, we irrigate, we antisepticize, we deplete, we use counter-irritants, we stimulate, we constringe, and we cauterize—and the wretched pathologic processes keep on and on until cornea and eye are irremediably injured or ruined. Various explanations of this fact have been made, but to my knowledge the one that I am about to offer, and which seems to me to be one of perhaps several contributing causes, has not before been given.

2. With one eye infected we hasten to isolate the good eye, using all the methods, so well known, of shields, bandages, antisepsis, and various cautions to patient and nurse. Despite all our prophylactic measures, carried out with the utmost care and apparent success, the hitherto sound eye is, by-and-by, too often found infected, and we have to redouble our exertions to save that. Very often, indeed, the eye last affected is most affected and most injured.

II. A METHOD OF INFECTION.

The explanation of these two characteristic features, or rather *one* explanation of them, I believe to be the rôle played by the nose and the lachrymal excretory apparatus as transferring agents and hiding-places of the specific germs.

1. Nose-picking with this class of patients is more common than eye-rubbing. While, therefore, the contagium may have been transferred directly to the eye, it is quite as reasonable to suppose that it may first have passed through the nares, duct, sac, and canaliculus.

It is a work of supererogation to set forth before this audience of specialists the well-known facts of the interdependence of nasal and ocular disease. I have elsewhere recapitulated these facts, and need only say that a large number of observers have demonstrated that the ocular drainage-system may be the passageway for the transfer of morbific material from the antrum of Highmore, and the nasal or post-nasal cavities, to the eye. Every modern book on rhinology speaks of this, and every physician has seen evidences of it. This, however, has been shown or suggested only in so far as relates to phlyctenular and sundry of the slighter forms of conjunctival and corneal disorders. It seems strange that no one has taken the suggested step of applying the same explanation to the origin of the more virulent types of gonorrheal and contagious purulent disease.

---

[1] Abstract of a paper read before the Section of Ophthalmology of the American Medical Association at Detroit, June, 1892.

2. Whether or not the primary contagium may have reached the eye directly or by way of the nose, the canaliculus, sac, and duct will most certainly be the secondary sinuses and hiding-places of the specific germs or septic material. We kill the gonococcus upon or in the conjunctiva, but do not think of the enemy intrenched just beyond the border, waiting to break over the moment our antiseptic army withdraws. Or the analogy of the Channel tunnel—both ends in possession of the French—may strike the English imagination better. In purulent ophthalmia the congestion of the parts, and doubtless often the stenosis, more or less complete, of the lumen of the canaliculus and duct, prevent any effective antiseptic irrigation of the same by natural capillarity or unaided excretion. Expression of the canaliculus and sac-contents, and aided irrigation in the manner I have advised in dacryo-cystitis (*N. Y. Med. Journ.*, June 4, 1892), would perhaps do in light cases, and when the physician does not slit the canaliculus. The thick, purulent, and gummy character of the ocular secretions can find little or no passageway through the tight punctum and canaliculus, whose lumen is narrowed or quite closed by the swollen tissues about it or forming it. Hence the living germs lying just beyond the action of our ordinary antiseptic agents, and multiplying by millions in a few hours, have an excellent breeding-ground, whence, continually erupting through the punctum, we have a prolific fountain of fresh infection.

3. Passing down the duct also, is it not natural that the germs should readily find their way around the turbinated bones and up through the opposite duct to the other eye, and thus, despite all our isolation and prophylaxis, infect that by means of the tunnel or secret passageway we had forgotten? If this seem somewhat too long a journey, repeated direct infections of the nares by the fingers would explain the late appearance of the disease in the second eye.

The foregoing explanation finds corroborative support in the fact that the nasal mucous membrane, and probably therefore the lining membrane of the duct, sac, and perhaps (though doubtless to a lesser degree) also of the canaliculus, are more resistant to the microbes of suppuration and gonorrhea than the conjunctiva. It is a curious fact, this of the extraordinary sensitiveness of the ocular conjunctiva to the injurious action of these germs, and it indicates that these find in the ocular tissue a food exactly to their liking, which they are therefore continually seeking—trying always to get away from the less fertile ground of the nasal mucous membrane and into the richer soil of the ocular analogue. The granulations of trachoma have been found in the canaliculus and sac, but not, I believe, in the nose.

A recent German writer has noticed that young infants of gonorrheal mothers often show evidences of the specific infection (mucous patches) in the mouth, and that sometimes, following these oral ulcers, there ensues ophthalmia neonatorum. He also alludes to the fact that throughout the entire body the ciliated or cylindrical type of epithelium of mucous membrane is very resistant to the gonococcus, whilst in that lined by squamous or round-celled epithelium the microörganism multiplies prodigiously. This, therefore, explains why the nose and duct escape injury, whilst the conjunctiva is destroyed. It may also be added that perhaps the eye of the infant may be infected without the intermediation of the nose, by means of the hands of the careless mother or nurse (even by the child's hands), that may convey the virus directly from the mouth to the eyes.

III. The Treatment

suggests itself. The next case of gonorrheal ophthalmia I have I shall at once slit the canaliculus clear into the sac, cleanse, and antisepticize the latter precisely as I do the palpebral sulci, and thoroughly syringe the duct with the antiseptic solution. This I shall do as often and as carefully as the distinctly ocular cleansing and antisepsis. I shall also direct the same solution or a stronger one to be snuffed up the nose.

IV. The Prophylactic Measures

are quite as clearly indicated. With one eye certainly infected, I would, besides the usual prophylactic procedures, at once also open the canaliculus of the sound eye, and, while the danger lasts, irrigate the sac and duct thoroughly and repeatedly. The nasal douche also should not be neglected. The patient's hands and fingers should of course be kept aseptic and away from his nose just as carefully as from his eyes.

It may be said that this is all theory, and that I should have proved it by clinical experience before advocating it publicly. I have by experience found some confirmative evidence of the theory, but at present my only answer is that since the idea first occurred to me I have had no suitable cases, and my interest in your patients leads me to advise you to try the plan. It might save a few eyes that would be ruined whilst I alone were experimenting. I would prefer to be the father of a false theory rather than that a single eye anywhere should be blind for lack of one little method of treatment that at least seems rational, and the application of which, if it do no good, can certainly do no harm.

MEDICAL PROGRESS.

Pure Culture of Tubercle-bacilli from Sputum.—KITASATO (*Archiv für Hygiene*) has succeeded in obtaining pure cultures of tubercle-bacilli from the sputum of tuberculous patients. The morning expectoration was received in sterilized receptacles, and the individual masses of sputum were isolated by means of sterilized instruments and washed at least ten times with sterilized water. Examination of portions of the mass often disclosed the presence of tubercle-bacilli exclusively, and inoculation of glycerin-agar or blood-serum yielded pure cultures of tubercle-bacilli. It was also found that most of the bacilli in the sputum, as well as of those found in the contents of pulmonary cavities, were dead.—*Corr.-bl. f. Schw. Aerzte*, 1892, No. 9.

A Bacillus Resembling that of Influenza in the Saliva of Domestic Animals.—FIOCCA (*Centralbl. f. Bakteriol. u. Parasitenk.*, 1892, xi, 13, p. 406) has found in the saliva of dogs and cats a bacillus in appearance and culture closely resembling that described as the cause of influenza, and being pathogenic for rabbits, guinea-pigs, young rats, and mice.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

SATURDAY, JUNE 11, 1892.

THE AMERICAN MEDICAL ASSOCIATION.

As we go to press, the American Medical Association is in session at Detroit. The work of the first two days in the principal bodies of the Association is succinctly reflected in the reports presented elsewhere in the current number of THE NEWS.

The Association has laid out a vast deal of work for itself, which the experience of the past and the representative character of the participants lead us to hope will be well and creditably done. Certain ethical matters of paramount importance to the well-being of the medical profession of the United States will also come up for consideration, and these we have no doubt will be disposed of in a manner worthy of the nobility of a great profession.

As will be seen by the report of the general session, an important innovation has been made by the establishment of a General Business Committee, as a result of which a radical change is effected in the management of the Association.

The Association is to be congratulated on holding its meeting at Detroit, and its officers and the various committees deserve the warmest thanks for the admirable arrangements, scientific and social, and for the cordial welcome extended to the host of visiting physicians.

SOCIETY PROCEEDINGS.

AMERICAN SURGICAL ASSOCIATION.

Thirteenth Annual Meeting, held at Boston, May 31, June 1 and 2, 1892.

(Continued from page 641.)

IN the discussion of Dr. Homans's paper (see p. 645), DR. A. VANDER VEER, of Albany, stated that in looking over his notes he had found that uterine fibroids were most prolific between the ages of thirty and forty-eight years. The hemorrhage, which is usually the symptom that attracts the attention of the patient, is dependent not so much upon the size of the tumor as upon its location. The hope that after the menopause is reached the fibroid will subside is not always realized. In some cases the tumor seems to take on a more active growth at that time. As to treatment, curetting and packing with iodoform-gauze will often stop the bleeding. If this fails in small fibroids, oöphorectomy invariably cures except in the case of soft myomas. The danger in treatment depends upon the size of the tumor. The large growths are responsible for the mortality after operation.

DR. J. EWING MEARS, of Philadelphia, contended that if the only reason for the removal of the tumor was from an esthetic point of view, on account of the large size of the abdomen, the patient's desire alone should not be the guide for operation. He related the case of an unmarried woman, who solicited the removal of a growth on account of the distention of the abdomen produced by it. He refused, and she passed into the hands of another practitioner, who did operate, the patient dying five hours later. Dr. Mears divided the cases requiring operation into two classes. Operation is justifiable, first, if the hemorrhage endangers life; second, if the pressure-symptoms are such as to make life unbearable. There are, however, many cases in which, under palliative treatment, life may be prolonged, the patient rendered comfortable, and made able to enjoy life. He had found electricity palliative, but not curative. The tumor is sometimes reduced in size.

DR. GEORGE W. GAY, of Boston, spoke of the treatment of fibro-cystic tumors, and referred to the practice of tapping. He reported one case in which he began tapping in 1879, repeating the procedure every two or three weeks for four years; ninety tappings in all were made. The patient is now in good health, with a large abdomen, but has not been tapped for years. Other similar cases were reported.

DR. ROBERT ABBE, of New York, referred to the value of the Trendelenburg posture, and early control of the arterial supply to the uterus in these operations. He was rather surprised at Dr. Homans's assurance that death from hemorrhage was rare. He had thought the contrary. It is the symptom that frightens the patient and alarms the surgeon. He had had fair success with electricity, and would advise it in many cases. The tumor will grow, but the hemorrhage will cease.

DR. HOMANS, in conclusion, stated that the application of strong currents of electricity to the interior of the uterus caused some change in the mucous membrane, checking the bleeding, but it did not prevent conception. It is his custom to advise patients with

fibroid tumors not to marry. Cases bearing upon this point were related.

SECOND DAY—JUNE 1ST. *Morning Session.*

The morning session was devoted to a visit to the Massachusetts General Hospital, where a number of interesting cases were shown and the methods of work demonstrated.

Afternoon Session.

DR. N. P. DANDRIDGE, in Cincinnati, read a paper on "The Surgery of the Tongue," devoting especial consideration to the subject of operative procedure in malignant disease. Carcinoma of the tongue, as a rule, appears in the form of epithelioma, running its course in about a year and a half. In many cases it develops from an indifferent lesion that has been subjected to continued irritation. Neighboring glands are usually affected, sometimes within three months, at other times not for six or nine months after the appearance of the disease. Ulcerated epitheliomata may require differentiation from tuberculous and syphilitic ulceration.

The history of operations in carcinoma of the tongue was considered and the propositions laid down by Treves were concurred in: the organ should be removed by means of the scissors or the knife; the removal should, as a general rule, be effected through the mouth; every means should be taken to reduce the hemorrhage to a minimum; when the floor of the mouth is involved, or the glands extensively involved, the incision should be carried out through the neck.

The various methods of operation — Whitehead's, Morant Baker's, Kocher's, and Volkmann's—were described in detail.

In Whitehead's operation a gag is employed, care being taken to avoid pressing back the jaw and interfering with respiration. The patient occupies a sitting position. A ligature is passed through the anterior part of the tongue and the section is made with scissors. If the frenum and the anterior pillars of the fauces are completely divided, the tongue can be drawn freely from the mouth. The organ is then separated by free incisions with the scissors, until the main artery is reached. This is seized with forceps before division. Before completely severing the tongue, it is desirable to pass a loop of silk through the glosso-epiglottidean fold, in case it may become necessary to make traction on the posterior floor of the mouth. The parts are then rendered as aseptic as possible by swabbing them with 1 : 1000 solution of mercuric iodide, and painted with iodoform styptic solution—Friar's balsam in which the spirit is substituted by a concentrated solution of iodoform in ether, one part in ten of turpentine having been added to the ether. This varnish is repeated daily. The patient is not kept in bed, but is encouraged to go in the open air. Whitehead has reported 104 cases of total removal of the tongue by this method, with 20 deaths, or 19.20 per cent. Of 61 patients, 15 survived the operation one year; 4, two years; 2, three years; 4, five years; and 1, six years.

In Baker's operation a thread is passed on each side of the tongue half an inch from the median line. The attachments of the tongue on the side are divided with scissors, keeping close to the lower jaw. The mucous membrane is next divided in the median line and the two halves of the tongue are separated by the finger. The diseased half of the tongue is then removed with the écraseur. Enlarged glands should be searched for and removed either from the floor of the mouth or by an external incision.

Kocher's operation has been commended in cases in which the floor of the mouth and the submaxillary glands are involved. It is, however, too serious an operation for cases in which the disease is confined to the tongue. Tracheotomy is first performed, and the fauces are plugged. An incision is then made along the anterior border of the sterno-mastoid muscle. From the first, an incision is made from the middle of the sterno-mastoid muscle to the hyoid bone and along the anterior border of the digastric muscle to the jaw. The flap is turned up, and the facial artery and vein and the lingual artery are tied. The submaxillary fossa is then completely cleaned out. The attachments of the tongue are now divided, and the organ is drawn through the opening and removed either in part or in whole by scissors or the galvano-cautery. If the whole tongue is removed, the lingual artery of the opposite side must be ligated through a separate incision. The tracheotomy-tube is allowed to remain, and the wound is kept packed with gauze soaked in a solution of carbolic acid, which is changed twice a day, when food is given. In fourteen cases there was only one death.

Volkmann's method has been attended with extraordinary success, there having been only two deaths in ninety-one operations. The patient is seated in a chair. If the tongue can be brought forward, a resection is made with knife or scissors, and the mucous membrane is brought together, or if a strip of healthy tongue is left it is turned around so as to make a short, broad organ. If the disease is too extensive to admit of this method, a traction-thread is passed through the tongue, and the organ is drawn forward. The canine or first molar tooth is extracted; an incision is made downward from the corner of the mouth, and the lower jaw is divided. The portions of bone are separated, and the attachments of the tongue are divided. The cut surfaces are covered with mucous membrane, and the bone is wired. A drainage-tube is placed in the tonsillar fossa and brought out at the lower extremity of the incision.

If operation is not indicated, or if the patient refuses surgical interference, the application of a powder containing iodoform, one grain; morphine, from one-sixth to one-half grain; borax, three grains—directly to the painful spot—has been recommended. Cocaine has been resorted to, either by direct application or by hypodermatic injection, but there is danger of the establishment of the cocaine-habit. The excision of a portion of the lingual nerve has been recommended, but the relief thus afforded may be only temporary. For the relief of salivation and fetor, various antiseptic mouth-washes may be employed. If, on account of the pain, there is difficulty in swallowing, relief may be afforded by painting the surface freely with cocaine just before the administration of food, or a soft-rubber tube may be passed into the esophagus.

The following conclusions were submitted: 1, sufficient experience has been accumulated to show that the removal of carcinoma of the tongue prolongs life, adds to the comfort of the patient, and affords reasonable

hope of a permanent cure; 2, all operations should be preceded by an effort to secure thorough disinfection of the mouth and teeth; 3, in the treatment of persistent ulcers and sores on the tongue, caustics are to be avoided and all sources of irritation removed; 4, persistent sores on the tongue should be freely removed by knife or scissors if they resist ordinary treatment; 5, when the disease is confined to the tongue, Whitehead's operation should be employed for its removal; 6, in this operation the advantage of preliminary ligation of the lingual artery is not definitely settled, but the weight of authority is against its necessity; 7, the advantage in unilateral disease of leaving one-half of the tongue must be considered undetermined, but the weight of positive experience is in its favor; in splitting the tongue into lateral halves, Baker's method of tearing through the raphé should always be employed; 8, a preliminary tracheotomy in ordinary cases adds an unnecessary element of danger in the removal of the tongue; 9, when the floor of the mouth has become involved or the glands are enlarged, Kocher's operation should be employed, omitting the spray and preliminary tracheotomy; 10, removal of the glands by a separate incision, after the removal of the tongue, must be considered insufficient; 11, Volkmann's method still rests on individual experience; its true value cannot be determined until it has been subjected to trial by a number of surgeons; 12, thorough and complete removal should be the aim of all operations, whether for limited or extensive disease; 13, by whatever method the tongue is removed, the patient should be up and out of bed at the earliest possible moment, and should be generously fed.

DR. D. W. CHEEVER, of Boston, referred to the question of diagnosis of ulcers of the tongue. Dyspeptic ulcers appear in successive crops. They are not indurated, and can be made to heal by simple treatment. In the diagnosis of syphilitic ulcers, the previous history is at times of service. In doubtful cases, two weeks of anti-syphilitic treatment should be employed. Lupus or tuberculous disease of the tongue is not as common as carcinoma. Tubercle-bacilli are not always found. Tuberculous ulcers form and re-form; some heal and leave scars. Carcinoma does not heal, but goes on extending. In lupus, the sublingual and submaxillary glands are early infected. True carcinoma is almost always at the side of the tongue; the infection of the glands is usually speedy. Dr. Cheever advised the removal of enlarged glands, but he did not think that the neck should be treated as is the axilla. He thought that malignant affections of the mucous membrane are more rapid in recurrence than are malignant affections of the skin and glandular structures. In carcinoma of the tongue, the disease as a rule recurs in from four to six months. In simple carcinoma of the tongue, without glandular involvement, preliminary tracheotomy is not required. Dr. Cheever operates with the patient in the sitting position, and not thoroughly etherized. He has never tied the lingual artery for carcinoma. If the disease is limited, partial amputation of the tongue seems to have been as successful as total removal. Recurrence almost always takes place in the glands and rarely in the stump. Reference was made to the remarkable recovery of the ability to speak in cases in which the tongue has been completely removed.

DR. L. MCLANE TIFFANY, of Baltimore, stated that in considering operative interference a distinction should be made between cases in which the disease involved the anterior portion of the tongue, and those in which the disease has begun more or less posteriorly and there is glandular involvement. In the latter cases, he prefers division of the lower jaw, either at the symphysis or at the side. He thinks it wise to remove the glands beneath the tongue, even if not enlarged. In this way one of the routes of systemic infection is removed. If the posterior portion of the tongue is involved, permanent recovery is rare; if the glands are involved, recovery is still more rare. Dr. Tiffany has obtained the best results by dividing the jaw and securing drainage from below. The incision is not closed, and ample opportunity for drainage is provided. The operation is done with the patient on the side and the head near the edge of the table, full anesthesia with chloroform being employed. If the tongue is excised for tuberculous ulceration, the ulcer rarely recurs, although the general tuberculous disease may progress.

DR. T. F. PREWITT, of St. Louis, remarked that the selection of the operation depends largely upon the extent and location of the disease of the tongue. If the carcinoma is limited to the tongue, an operation through the mouth is sufficient. If the floor of the mouth be involved and the disease has extended to the bones, something more is needed. In one or two instances he has resected portions of the jaw. He does not think that the primary hemorrhage is to be dreaded, but he has seen death from secondary hemorrhage in a case in which the arteries were diseased.

DR. W. H. CARMALT, of New Haven, stated that he has found it an advantage to perform preliminary tracheotomy. The most frequent cause of death after operation is septic pneumonia from the inhalation of infective material. Tracheotomy not only facilitates operation, but it obviates the danger of septic pneumonia. In the last case upon which he had operated, he first performed tracheotomy and packed the fauces. The patient did well. At the end of four days he removed the tracheal tube and allowed the patient to breathe by the mouth. On the next day the temperature had risen to 102°. The tube was immediately re-introduced, and the fauces packed, and in twenty-four hours the temperature was again normal. In cases in which the glands are involved, he advises the Kocher operation. In regard to the after-treatment, he has found that patients bear the presence of the esophageal tube better than its re-introduction.

DR. R. F. WEIR, of New York, stated that he has removed the tongue five times by the Whitehead operation, and five times by the Kocher operation, and has removed one-half of the tongue ten times by Whitehead's operation. If the floor of the mouth or the glands are involved, he prefers Kocher's operation. If there are signs of glandular enlargement in the submaxillary space, he considers it good surgery to cut down in front of and behind the sterno-mastoid muscle and examine the condition of the lymphatic glands in this situation. In the Kocher operation he prefers tracheotomy, and if there is sufficient time he does it a few days before removing the tongue. He considers tracheotomy a great advantage both at the time of operation and afterward.

DR. A. G. GERSTER, of New York, stated that he has

extirpated the tongue in various ways in nineteen cases. He thinks that the more thorough and radical the operation, the better are the results. He advocates removal of the affected glands, and the performance of tracheotomy. This enables the operation to be more thoroughly done, and with more comfort to the surgeon and less danger to the patient. In this region, as in every other region of the body, thorough operation requires thorough anesthesia.

DR. T. J. DUNOTT, of Harrisburg, reported a case in which the tongue was greatly enlarged and protruded from the mouth. The operation was done several years ago, and the patient is still living and well.

DR. JOS. RANSOHOFF, of Cincinnati, reported a case in which he operated by the Mordant Baker method four and a half years ago, and there has been no relapse. In other cases in which he has operated, he has not obtained the same success. In every case in which he does not perform a Kocher operation, he makes an incision in the submaxillary triangle in order to put in a large drainage-tube reaching to the floor of the mouth. This opening gives an opportunity for the examination of the glands. If there is enlargement, the glands can be turned out or the incision enlarged if necessary.

DR. W. H. CARMALT, of New Haven, Conn., read a paper entitled "Conditions Demanding Excision of the Globe of the Eye." He stated that, as a rule, the question of the propriety of enucleating an eye will be referred to the specialist. There are cases of emergency, however, in which the general surgeon is called upon to act promptly. In the consideration of this subject, it at once presents itself from two different standpoints, accordingly as the eye is blind or retains a more or less useful degree of vision.

In the case of blind eyes, the objections to the operation are the dangers of the operation *per se*, and the cosmetic effect. Meningitis has occurred in some cases operated on in the acute stage of suppurative panophthalmitis. In these cases, the organ should be removed as soon as the evidences of suppuration are unmistakable. In cases of lacerated or penetrating wounds, with loss of vision, the operation is better performed before suppuration occurs, or as soon as the evidences of suppuration are sufficiently plain. There is no one condition for which eyes are so frequently excised as sympathetic ophthalmitis (threatened or actual). The pathology of the sympathetic process is still a matter of controversy. In a case presenting irritative symptoms indicative of the beginning of sympathetic ophthalmitis, with the other eye lost from injury or some form of disease, it is the duty of the surgeon to advise in the most unqualified manner the enucleation of the blind eye. The initiative stage is usually short. It is more or less rapidly followed by impairment of vision due to an organic lesion. In the acutely inflammatory stage of the sympathetic disease, the removal of the "excitor" is not so beneficial to the "sympathisor," and may be harmful, adding fuel to an already flaming fire. In these cases the operation should be postponed until the active process is subdued. In a small number (perhaps about 10 per cent.) of cases, the sympathetic inflammation may come on after the removal of the excitor, and in about 2 per cent. it has been thought to have been the result of operation. The conditions likely to give rise to sympathetic ophthalmitis are injuries and diseases. The injuries may be lacerating or perforating wounds, so severe as inevitably to result in atrophy of the globe; the lodgment of a foreign body in the interior of the globe; a penetrating wound involving the ciliary region. The diseases attended with ophthalmitis are recurring or chronic irido-choroiditis, from whatever cause; atrophy of the globe following purulent keratitis, or panophthalmitis, or in which ossific degeneration of the retina has taken place; atrophy of the globe from any cause, with pain in the ciliary region. Time does not confer immunity to sympathetic disease. The liability to the disease differs with the various injuries and diseases. Sympathetic ophthalmitis is more frequent after injuries than after non-traumatic affections, and of injuries, nothing is so potent as the lodgment of a foreign body in the eye.

The pain resulting from the intra-ocular pressure of a chronic glaucomatous degeneration is frequently so excessive as to justify the removal of the offending organ, other means of treatment having failed.

Various diseases of the eye leave the organ in a condition so inconvenient or repulsive that aid is sought for purely cosmetic purposes. The old operation of abscision of the anterior segment of the globe, in which more or less evisceration of the contents of the globe takes place, is followed by the same result as enucleation, and sympathetic ophthalmia may also result. Enucleation of the misshapen eye, with the introduction of an artificial substitute, is much to be preferred. The modern expedient of tattooing a white cicatrix of the cornea without staphyloma has resulted in sympathetic ophthalmitis.

The utility of the enucleation of blind eyes that are the seat of phosphenes is doubtful.

In regard to the enucleation of an eye only partially blind, the chances of accident or independent disease to the remaining eye are sufficiently great to justify the statement that nothing short of the certainty of ultimate blindness to both, or of death, can permit one to consider such a procedure.

Intra-ocular tumors are usually granulomata or carcinomata. They are sufficiently dangerous to life to demand the removal of the eye.

Extra-ocular growths are of greater variety of histologic structure. Sarcomata of the orbit often necessitate removal of the globe.

Should an eye that retains an appreciable degree of vision be removed in order to avert a threatened or prospective attack of sympathetic disease in the fellow? It is unjustifiable to remove an injured but still seeing eye, though it may be an excitor of sympathetic disease. The result of operative interference has not been sufficiently successful in averting the progress of the malady after it has begun, to warrant recommendation. The only condition rendering justifiable the removal of a still seeing organ, for sympathetic disease, is the presence of a foreign body in the eye, as it is likely to be followed by sympathetic disease.

The following officers were elected:

President: Dr. N. Senn, of Chicago.

Vice-Presidents: Dr. W. W. Keen, of Philadelphia; Dr. Chas. B. Porter, of Boston.

Secretary: Dr. J. R. Weist, of Richmond, Ind.

Treasurer: Dr. John B. Roberts, of Philadelphia.

Recorder: Dr. J. Ewing Mears, of Philadelphia.

Members of Council: Dr. Roswell Park, of Buffalo, and Dr. R. F. Weir, of New York.

Member of the Executive Committee of the Congress of American Physicians and Surgeons: Dr. N. McLane Tiffany, of Baltimore; alternate, Dr. James McCann, of Pittsburg.

It was decided to hold the next meeting at Buffalo, in May, 1893.

Dr. Roswell Park was elected Chairman of the Committee of Arrangements.

The following were elected to membership: Dr. Charles B. McBurney, of New York: Dr. John B. Deaver, of Philadelphia; Dr. Frederick H. Gerrish, of Portland, Me.; Dr. Wm. S. Halstead, of Baltimore, Md., and Dr. Henry R. Wharton, of Philadelphia.

THIRD DAY—JUNE 2D.

The following papers were read by title:

"Surgical Operations in Persons Suffering from Diseases Not Connected with that Necessitating the Operation, such as Chronic Malarial Poisoning, Diabetes, Organic Heart-disease, etc.," by DR. W. T. BRIGGS, of Nashville, Tenn.; "Ancient Contractures of the Hip-joint and Knee-joint," by DR. T. F. PREWITT, of St. Louis, Mo.; "A Case of Gastrorrhaphy for Diminution of a Dilated Stomach," by DR. ROBERT F. WEIR, of New York; "A Case of a rare form of Upward Dislocation of the Hip," by DR. LEWIS A. STIMSON, of New York; "Report of Operations upon Spina Bifida and Encephalocele," by DR. A. T. CABOT, of Boston; "Ulcer of the Stomach: Proposed Surgical Treatment," by Dr. E. H. BRADFORD, of Boston; "Congenital Cyst of the Pancreas: Removal; Recovery; Tumor of the Cecum, Causing Intussusception; Laparotomy; Reduction of Intussusception and Removal of Tumor; Death," by DR. M. H. RICHARDSON, of Boston; "Hernia of the Left Fallopian Tube," by DR. JOHN HOMANS, of Boston; "A Case of Sarcoma of the Tonsil; A Case of Chronic Appendicitis," by DR. STEPHEN H. WEEKS, of Portland, Me.; "The Diagnosis and Successful Treatment of Some Cases of Cerebral Tumor," by DR. F. S. DENNIS, of New York; "Lymphangioma of the Neck," by DR. C. B. NANCREDE, of Ann Arbor; "Successful Case of Enterectomy and Enterorrhaphy, with Removal of Sarcoma of Mesentery; Successful Case of Trephining of the Spine for Fracture of the Lamina and Partial Dislocation of the Bodies of the Eleventh and Twelfth Dorsal Vertebræ," by DR. JAMES MCCANN, of Pittsburg; "A Case of Removal of an Enlarged Accessory Thyroid Gland at the Base of the Tongue," by DR. J. COLLINS WARREN, of Boston.

The morning session was held at the Boston City Hospital, where a number of interesting cases were exhibited.

In the afternoon, at the invitation of the President of the Board of Health, the Association inspected the method employed for the disposal of the city sewerage, and visited the Hospital under the charge of the Board of Charities.

The Association then adjourned to meet in Buffalo in May, 1893.

AMERICAN ACADEMY OF MEDICINE.

Seventeenth Annual Session, held at Detroit, Michigan, June 4 and 6, 1892.

FIRST DAY—JUNE 4TH.

THE session was opened by DR. R. LOWERY SIBBETT, the First Vice-President, in the absence of the President, Dr. P. S. Conner, of Cincinnati.

DR. MCINTIRE read the Report of the Council. The Council expressed its belief that there was a slow but steady rise in the standard of medical education in America, as indicated by the adoption of a four years' obligatory course by several medical schools; by the new regulations for preliminary education adopted by the Illinois State Board of Health; by the raising of the standard for preliminary education for the study of medicine by the Regents of the University of New York; by the acknowledgment of the value of a collegiate education by the Medical Department of the University of Pennsylvania, in admitting to advanced standing graduates of those colleges in which the curricula include certain studies; by the announcement, recently made, that the American University contemplated by the Methodist Episcopal Church will be open only to the graduates of colleges—*i. e.*, making a degree necessary for entrance upon post-graduate study.

The Academy has an active membership of 543, and 19 honorary members, 10 of which are residents of Europe. Nine Active Fellows and 2 Honorary Fellows died during the year.

Five Bulletins of the Academy were issued during the year.

Sixty-five new Fellows were elected.

The Report of the Committee on Eligible Fellows was read by DR. JUSTIN E. EMERSON. The Committee devoted its energies mainly to preparing a list of college alumni that are members of the medical profession in the United States, and a list of 3455 names was obtained of those that, if not already Fellows of the Academy, or irregular in their modes of practice, are presumably eligible to fellowship.

An effort has been made to send the Bulletin of the Academy, stating its objects, especially to the alumni of prominent Southern and Western colleges, among which the Academy has almost no Fellows.

An inspection of the comparative number of presumably living medical alumni of the colleges catalogued by the Committee, shows that out of 4000, about 14 per cent. have ceased to practise their profession.

There are probably 5000 practising physicians that are college alumni, which means that not more than 5 per cent. of the physicians of the United States have had the liberal education that such graduation implies. This estimate makes no allowance for any large percentage of physicians of foreign birth and education.

The Report of the Committee on the Comparative Value of Academical Degrees was read by DR. MCINTIRE. The Academy adopts, provisionally, the requirements of the Ohio College Association for the degree of A.B. as the minimum standard of acceptance, with the single possible exception of the length of the college year.

The Committee has also endeavored to express the standard of the A.B. degree, by defining what its pos-

sessor should be, rather than by enumerating the studies that he should pursue to attain that degree; by defining the product rather than the process.

Educational advantages offered and made use of do not necessarily produce a skilled practitioner of medicine. Aptitude and tact are also required. Knowledge of medicine and technical skill do not include all that a physician should possess. Training in this direction may develop the specialist at the expense of the man. An educated physician should have a disciplined mind, the essence of which is the power to concentrate attention for a long time upon any subject presented. Having this power he can appreciate the advance in science and literature, though he may not be able to assist in it.

The aim of the Academy has been to direct and encourage medical students in the line of studies most likely to produce the best results to the greatest number.

A third line of research proposed by the committee was a comparison of the English A.B. with the American degree, for the purpose of obtaining additional evidence for the one mission of the Committee—an academic standard for a liberal education.

DR. A. L. GIHON read the proposed changes in the Latin certificate granted by the Academy to its Fellows. The changes were suggested by Dr. Steiner, and were intended to give recognition to those that, while not having a college degree, have nevertheless had an education regarded as equivalent.

The changes were adopted, and Dr. Benj. Lee was appointed to the position on the Committee made vacant by Dr. Steiner's death.

DR. ELBERT WING, of Chicago, read a paper on "The Relative Value of Academical Training in Undergraduate Medical Study; an Analysis of the Personal Experience of the Writer." He stated that a satisfactory discussion of the subject must include the following points:

1. The quality of the collegiate training of the writer. 2. The training, collegiate or otherwise, of his classmates. 3. The curriculum in the medical college, and the methods of teaching the several branches. 4. The result of the work as realized by daily quizzes, and by final examination. 5. The results as shown by subsequent success in professional work.

From the standpoint of a teacher, the men of college grade are easily superior to the others in quickness of perception and in breadth and firmness of grasp of any subject submitted to them, other things being equal; but they are not always equal, *e.g.*, when students are older and more mature in every way than the average of those who hold college degrees.

DR. W. D. BIDWELL, of Washington, D. C., read a paper on "The Value of Academical Training Preparatory to the Study of Medicine." It is only when the common-school education is completed, only when with increasing development of body and concomitant expansion of mind the academic course is entered upon, that the reasoning faculty is brought into full play, and the youth comprehends the relation and interdependence of mind and body. Dr. Mark Hopkins always insisted that the object of a college training was to develop the whole man, mentally, morally, and physically. With this idea, at Williams college men studied first as physical beings in a physical universe, then as rational creatures, and lastly as having a moral nature enabling them to appreciate their relations and obligations to their Creator.

We must be *men*, strong-bodied, broad-minded, noble men, before we can be physicians worthy of the name. What then can be of greater value as a preliminary to medical study than such a course of training as will transform the raw material of uneducated youth into lords of the universe.

DR. H. B. ALLYN, of Philadelphia, read a paper on "The Value of Academical Training Preparatory to the Study of Medicine." The value of a college education is not to be estimated from the prescribed course of study alone, but also from all those influences to which a student is exposed during his college course.

These influences help very decidedly to fit a man for his social duties, and render him, by just so much, the superior of those who have not had equal advantages. The point to be made is, that a wise use of the opportunities afforded by college life, apart from the course of study pursued, makes a man larger, broader, and better equipped for success in the social sphere than he could otherwise have been; and every man of experience knows that ability to understand men and women, to get along with and please them—the social *tactus eruditus*, it may be called—is not the least significant element in professional success.

Perhaps the most important advantage of a preliminary college education lies in the fact that it makes the subsequent acquisition of medical knowledge much easier than it otherwise would be.

There is abundant evidence that a preliminary college education enables a student to save much time and labor in his medical course. After all, it is only making a specific application of the well-known truth—that the more a man knows, the easier it is for him to acquire additional knowledge. We progress by steps, not by leaps.

In summing up it is to be said that an academic course preparatory to the study of medicine has a twofold value. In the first place, the college influences, apart from the course of study, increase the extent and comprehensiveness of the student's mental vision, help to rid him of pretensions, prejudices, and vanity, supply him with a valuable acquaintance, inspire him with laudable ambition, and spur him to praiseworthy effort.

In the second place, the course of study stores the student's mind richly, in proportion to his capacity and industry, with knowledge that much facilitates his subsequent study of medicine. He comes to his chosen profession taught by experience how to study, how to "see straight and think clearly," and he exhibits a quickened apprehension and a more thorough grasp of the subjects presented than do his fellows.

One who practises medicine in a large city and has not had an academic education before studying medicine is very seriously handicapped.

In the discussion, DR. HELEN F. WARNER stated that education is no proper substitute for brains. The most elaborate polish will not make a quartz crystal equal to the roughest diamond. Nevertheless, on an average, college-bred students will be found superior to those without such training.

Technical training is more immediately productive

but less educative of the whole man than the more general literary training. But a man in college acquires something more than knowledge, something that can best be expressed by the much-abused word culture. This softens his manners, gives him ease, and wins him respect. Wisdom, tact, and kindliness are almost as essential qualities for a physician as learning or skill, and these cannot be taught in medical schools.

DR. L. HARRISON METTLER, of Chicago, read a paper on "The Value of a Collegiate Degree as an Evidence of Fitness for the Study of Medicine." He objected to making the A.B. degree essential for the study of medicine. He regarded such a step as odious class-legislation that would be detrimental to the best interests of the Academy. Some men have fine abilities, but have not been able to take a preliminary college training. The possession of a collegiate degree is not evidence of fitness for the study of medicine. Some greatly excel in medicine who have had no college degree. A collegiate education is a luxury, not a necessity.

DR. SELL stated that there are isolated cases of high professional attainments among men of no college training, but these men are exceptional.

DR. MCINTIRE stated that one of the objects of the Academy is to suggest to young men the best way to prepare themselves for the study of medicine. They should have a liberal education first, and then a technical education.

A liberal education is best attained in this country by a course in one of the colleges, whether the degree given be A.B. or B.S., or Ph.D. The Academy asks the colleges to certify that the B.S. or Ph.D. be up to the standard of the A.B., and if they are not, then it is not willing to accept as members those having such degrees. The physician should, first of all, be an educated man.

DR. R. L. SIBBETT expressed the view that five years should be spent in preliminary study before taking up a profession, and a choice of a profession should not be made until a man is twenty-one years old.

DR. P. S. CONNER, of Cincinnati, then read the Address of the President, on "Essentials and Non-essentials of Medical Education." He stated that four years should be spent in preliminary study, three of them in collegiate courses.

The essentials are three: (1) the body; (2) the morbid conditions to be treated; (3) the remedial measures to be applied in the treatment.

Anatomy must be the foundation study. All anatomic facts are not of equal value, however. A knowledge of the origin and insertion of a muscle is of less value than a knowledge of its general position. In the same way, a knowledge of the general circulation is of more importance than ability to describe the branches of the internal maxillary artery. Anatomy should be studied by dissection.

Physiology is another essential study. The great general principles of development, nutrition, and decay are most important; not so theories and speculations and calculations.

Chemistry is a non-essential study of the first order, except for the examination of urine, of the composition of calculi, and of impurities of water. It should be studied in the laboratory. More should be studied in preliminary courses and less in the medical schools. The Materia Medica of the present deals with active principles, extracts and alkaloids, not with botanic names. Therapeutics, not botany, is what a student needs—when to prescribe, what to prescribe, and in what dose, not where the crude drugs come from or their botanic or chemic names.

Hygiene and medical jurisprudence are non-essentials for the most part. The former teaches the student little but bacteriology, except what he should hear from the chair of medicine. It should be an elective branch. Medical jurisprudence is usually taught by a lawyer who has no conception of what constitutes careful treatment by the physician. Such teaching as is necessary should be left to the surgeon, who, in his lectures, can instruct his classes upon the legal aspects of their responsibilities.

Bacteriology is very important, but instruction in it should not be exceedingly minute. The student should be taught what forms of bacteria are dangerous; how to prevent infection by them and how best to destroy them when it is desirable to do so.

Pathologic anatomy should be taught in the laboratory by means of dissections and the demonstration of specimens.

The most important branches are the practice of medicine and the practice of surgery, of which obstetrics is a branch. They should be given as much time as possible.

The common diseases should be dealt with. He is a poor teacher who spends days and weeks in talking of any one subject. A selection of subjects should be made, and the student given clear conceptions of the most important diseases and surgical affections. Half-educated physicians do more harm than the uneducated.

Didactic lectures are not useless if given by qualified lecturers with clear perceptions of what it is most important to impart.

Clinical teaching is of great value. Four-fifths of the clinics given in our colleges, however, would be just as good if the patients were miles away. The student should be brought in contact with the patient, so that he can investigate for himself.

As to specialties, they are generally non-essential.

Among elective studies should be placed ophthalmology, otology, rhinology, and gynecology.

As regards medical education, there is ground for congratulation. Above all, the student must have a logical mind and common sense. With these, the more a man can know the better. There should be a year of purely practical training at the bedside. The great end and aim of medical education is to make not scientists or scholars, but healers of the sick.

DR. THOMAS F. MOSES read an elaborate and carefully prepared paper on "The Value of the General Preparatory Training afforded by the College as compared with the Special Preparatory Work suggested by the Medical School in the Preliminary Education of the Physician." He stated that a good education, natural talent, and industry are essential to the acquirement of knowledge of medicine.

The profession has been aroused to the needs of medical education. Three years of study are now required, and in many colleges a fourth year has been added. The defects that exist to-day are: that too little

time is occupied in preliminary education; there is too much didactic and too little clinical work, and the courses of study are too short.

Even the best schools still let improperly qualified men enter upon the study of medicine. The value of an academic degree is becoming appreciated more and more. At Harvard the number of those possessing such degrees has doubled in a few years, and it is proposed to increase the requirements until a college degree will be necessary for entrance upon study.

The rapidly increasing number of State Boards of Health is an indication that the community is requiring a higher standard of medical knowledge, and is a good sign of the times. The Illinois State Board of Health recommends that the minimum age for graduation in medicine be twenty-five years. Dr. Moses would have it made twenty-four years.

DR. KEDZIE stated that the applicant for admission for entrance as a student of medicine should be a trained student. The matter is of less importance than the manner of study. It should inoculate the system—not simply produce a superficial scab. Any mental discipline is of benefit, and there are a number of lines of study that are of value. His advice would be to select those that will be the most useful in life, on the principle that an instrument is better than an ornament. The classics may discipline, but do not educate. The question is not how much, but how well.

DR. HERRICK considered the essentials of the study of medicine. The personality of the man is a strong element. If he lacks adaptability, he is unfit. Some men are unable to comprehend a principle, but only able to see a fact. Such are also unfit. A man must know *things* and the relations of things. The applicants cannot be too strictly limited to a class. A farmer may learn much anatomy by contact with the lower animals.

The paper of DR. CHARLES JEWETT, of Brooklyn, N. Y., on "The Newer Medical Education in the United States," was read by the Secretary.

It was stated that laws recently enacted by the Legislature of the State of New York, make it obligatory upon every matriculate in a medical college either to have a collegiate education or to pass a satisfactory examination before the Board of Regents of the University of the State of New York.

Among the notable additions in recent years to the curricula of the schools of New York and Brooklyn are hygiene, bacteriology, a more extended course in normal and pathologic histology, bedside teaching and other practical courses of instruction. The graded course is not the least important improvement.

In Bellevue and the Long Island College Hospital students are required to attend recitations on the principal branches of medicine. At the latter institution during the reading term the didactic lectures have been in great part replaced by class recitations from text-books.

The most important change has been in the adoption of the object-method in teaching. Clinical work consists in actual bedside instruction, in which the student is made to a certain extent to conduct the examination and prescribe the treatment, under the guidance of the clinical teacher. He becomes familiar by handling and practice with remedial measures, instruments, and their application.

Laboratories for practical instruction in physiology, chemistry, normal and pathologic histology, and bacteriology are provided. In obstetrics the clinical teaching is supplemented by a course in manikin training in which members of the class are drilled individually in the methods of diagnosis by abdominal and vaginal examinations, and in operative obstetrics. In surgery the operations that can be so taught are practised on the cadaver.

In a word, didactic teaching has assumed a far less prominent rôle in instruction, and has been replaced by bedside and laboratory teaching.

The right to practise medicine in New York is now conferred by license from the Board of Regents of the State University; a diploma from a medical college is no longer sufficient.

Appointments to the Board are made by the Regents from nominations submitted by the several medical societies. The complexion of the examiners is thus independent of political control and the plan has the support of the profession throughout the State.

DR. W. J. HERDMAN, of Ann Arbor, Michigan, referred to the changes that had taken place in methods of instruction at the University of Michigan in fifteen years. They showed a steady and persistent effort toward higher education.

A good English education is an entrance qualification. In 1889 and 1890 a four years' course was instituted, and three years of study became obligatory. In 1889 two-thirds of the students took the four years' course. Since then a four years' course has been the only one offered, unless advanced standing can be shown on the part of the student at entrance. No student can enter the medical department who could not enter the classical department.

A course has been adopted by which the student for two years pursues studies that lead up to the degree of B.S., and remains four years to take his degree of M.D., making six years in all. During the medical course the classes are graded as in an ordinary college course, and the students are subject to the same restrictions as obtain in other departments.

Modern medicine has become intensely analytical, but now more should be done in the way of prevention of disease.

DR. ELBERT WING gave a summary of the methods of, and facilities for, instruction in the medical colleges of Chicago. The Illinois State law requires four years of medical study prior to graduation, one year of which may be spent in reading medicine with a preceptor. This year is of little value. The exceptions to the law have been in the case of students who have taken the courses antecedent to the study of medicine offered by the literary departments of several universities.

Beginning with September, 1892, a four years' course, of seven months each, strictly graded, will be begun in the Northwestern University.

All the schools are embarrassed in the teaching of pathologic anatomy, because the Cook County Hospital is the only place where autopsies can be obtained in sufficient number to make them of much value to students, and owing to the rules of the hospital, the majority of autopsies must be made at such irregular hours and such short notice, that students cannot attend them.

Pathologic histology is fairly well taught in at least three of the medical colleges of the city.

There is a growing tendency to increase the amount of clinical teaching at the expense of the didactic. There is a tendency to make both preparatory and undergraduate courses too extended.

SECOND DAY—JUNE 6TH.

DR. GIHON, Chairman of the Nominating Committee, recommended the election of the following officers for the ensuing year:

President.—Dr. Justin E. Emerson, of Detroit, Mich.

Vice-Presidents.—Drs. Thomas F. Moses, of Urbana University, Ohio; Charles Denison, of Denver, Col.; Silas D. Presbrey, of Taunton, Mass.; Herman B. Allyn, of Philadelphia.

Treasurer.—Dr. J. Cheston Morris, of Philadelphia.

Secretary.—Dr. Charles McIntire, of Easton, Pa.

Assistant Secretary.—Dr. Edgar M. Green, of Easton, Pa.

The Report of the Committee was adopted.

DR. R. LOWREY SIBBETT read a paper on "The Financial Aspects of the Academy," in which he objected to other methods of increasing the revenue of the Academy than by the charge for the *Transactions* and the initiation fees.

DR. PERRY H. MILLARD, of St. Paul, Minn., read a paper on "The Necessity and Proper Manner of Regulating the Practice of Medicine," which is to appear in a subsequent number of THE MEDICAL NEWS.

In the discussion, DR. LEARTUS CONNOR stated that the reason why medical education has been deficient is that teachers are tempted to fill their pockets at the expense of turning out unfit men. The remedy consists in having schools properly and efficiently endowed. It must be made profitable to do good teaching.

DR. VON KLEIN, of Cleveland, stated that he was educated under the methods of police supervision in Germany, but he could not approve entirely of Dr. Millard's suggestions. Anyone in Germany can practice medicine, but he cannot collect fees by law, cannot enforce his claim, or sign death-certificates.

DR. H. O. MARCY, of Boston, stated that medical education involves a duty not only to ourselves, but also to the public. Hence it is, as Dr. Connor has said, a question of sociology in its broadest sense.

Forty States have passed some law regulating medical practice. Massachusetts has no such law; it was defeated by money in the hands of irregulars and quacks, who even threatened Dr. Marcy with his life if he persisted in his efforts to have such a law passed. But the future is full of hope. Evolution is toward a better type of physician, and he is sure to come.

DR. WILLIAM PERRY WATSON, of New Jersey, stated that mixed boards worked together in entire harmony. The examinations show that there is a steady improvement in the quality of candidates.

DR. JOHN B. ROBERTS stated that Pennsylvania has no law because the regular men would not consent.

DR. VICTOR C. VAUGHAN, of Ann Arbor, Mich., read a paper entitled "Does a Classical Course Enable a Medical Student to Shorten the Period of Professional Study?"

He contended that length of time is an important element in the proper method of teaching medicine. Medicine is a science and an art. One must be familiar with the science if he would properly practise the art; consequently, he must be familiar with physics in its various branches of optics, acoustics, mechanics, and electricity; with chemistry, botany, microscopy, hygiene, bacteriology, physiology, histology, anatomy, and pathology.

These facts are generally admitted, but in many schools the branches are imperfectly taught by lecture and demonstration alone; these are essential, but laboratory practice is also essential. Along with the telling how to do, the educational process should include the *doing*. It is this that makes study in the German universities so popular.

Dr. Vaughan does not think that the average man who has had Latin and Greek can get as much out of a modern medical course in three years as the average man without classical training can get in four years. Classical training cannot supply a deficiency in any one of the physical, chemical, or biologic sciences. Classics are, however, of value, and students should, if possible, take the classical course. The man of classical training has a great advantage over one not so fortunate. While medical knowledge is best secured by experimental work, it is necessary that that knowledge be formulated, and the greater the ability to accurately formulate one's knowledge, the greater the chance that the student thinks clearly; and this power is best attained by a knowledge of the classics.

In concluding, Dr. Vaughan expressed the opinion that a classical training does not enable the medical student to materially shorten the length of time given to professional studies; but that the study of the classics does give to his professional knowledge a strength and an intensity that the man without the classical learning is not likely to feel.

AMERICAN MEDICAL ASSOCIATION.

Forty-third Annual Session, held at Detroit, June 7, 8, 9, and 10, 1892.

GENERAL SESSION.

FIRST DAY—JUNE 7TH.

THE meeting was called to order by the Chairman of the Committee of Arrangements, DR. HENRY O. WALKER, of East Detroit.

Prayer was offered by REV. T. F. DAVIES.

An Address of Welcome was delivered by GEN. R. A. ALGER.

DR. H. O. MARCY, of Boston, delivered the President's Address, taking for his subject, "Evolution in Medicine." He urged broad-minded liberality in dealing with so-called medical sects. Homeopathy, for instance, is best treated by neglect and the promotion of education.

The action of the New York State Medical Society in withdrawing from the Association was deplored. The reason for that action lay in the question of consultations. A strong plea was made for active coöperation of all State societies with the American Medical Association.

The *Journal* has a circulation of six thousand, and is established upon a paying basis.

The work of the American Academy of Medicine was heartily commended.

The practice of publishing surgical operations and other matters of cognate nature in the newspapers is to be deprecated.

Reform in coroners' laws was strongly advocated. The status of medical experts should be clearly defined.

It was urged that closer attention be paid to the study of intemperance and its treatment.

The coöperation of the Association was solicited for the purpose of securing pure foods. There should be appropriate supervision of railways, and provision for the most perfect hygiene attainable in cities.

Hearty coöperation in international congresses was strongly recommended. It has been announced that the British Medical Association will elect to membership only distinguished Americans. There is really little need for American students to go abroad for their medical instruction.

South America has given evidence of medical development.

The address was closed by reference to the memories of members of the Association that had died during the last year.

The Secretary, Dr. William B. Atkinson, urged more thorough organization on the part of State and local societies.

The Committee on Sections reported as follows:

Your Committee on Sections would report the following substitute for the amendment to the Constitution offered at the last annual meeting of the Association by Dr. J. C. Culbertson, to be known as Section VII of the Constitution, viz.: "That each Section of this Association shall elect an Executive Committee of three members, who shall be chosen from among those who have been in attendance upon the sessions of the Section for at least two years, to serve one, two, and three years, respectively; and that thereafter the retiring chairman of the Section shall take the place upon the Executive Committee of the retiring member of the Committee. It shall be the duty of the Executive Committee, in conjunction with the Chairman and Secretary, to give special attention to the interests of their own Section. These Executive Committees of the Sections so formed shall constitute the General Business Committee of the Association. They shall hold daily meetings during the sessions of the Association, and all matters of business not provided for by the Committee of Arrangements, the Board of Trustees, the Judicial Council, the Committee on American Medical Necrology, and special committees, shall be referred to them without debate.

"It shall be the duty of the General Business Committee to give especial attention to the interests of the Association, and to promote the welfare of the various Sections; to consider all matters of business referred to it by the Association, and report upon them at the earliest possible moment, when the Association may adopt or reject the report as it may deem best.

"It shall be the further duty of the General Business Committee to make and present the nominations for the officers of the Association and its Standing Committees, and recommend the time and place for the meetings of the Association.

"That the present numerical designation of the section of the Constitution entitled "Provision for Amendment," be changed by striking out the Roman numerals 'VII' and substituting therefor 'VIII.' All sections or parts of sections of the Constitution or By-laws of the Association not in harmony with this amendment are hereby repealed."

The presentation of the report was followed by warm discussion, but with the exception of the part relating to nominations for officers, the report was accepted.

The committee appointed for the purpose of securing the appointment of a Secretary of Public Health, who shall be a member of the Cabinet of the President of the United States, reported progress.

Second Day—June 8th.

The report of the Judicial Council was received. It decided against the legality of Dr. W. W. Potter, of Buffalo, N. Y., acting as a member of the Board of Trustees. The Council claimed that Dr. Potter was ineligible on account of his connection with the New York State Medical Society. Heated discussion followed. A motion was finally made and almost unanimously carried, to appoint a committee of five to confer with a committee of five from the New York State Medical Society to determine on what conditions the late division can be bridged. In the meantime, the permanent members from the New York Society remain in good standing in the Association.

The Committee on the Pan-American Medical Congress reported progress, stating that the outlook is encouraging. The Senate of the United States had unanimously passed the following, introduced by the Hon. John Sherman:

"Joint resolution: To authorize the President to invite certain governments to send delegates to the Pan-American Medical Congress. Resolved, by the Senate and House of Representatives of the United States of America, in Congress assembled, that the President of the United States be and he is hereby authorized and requested to invite the several governments of the republics of Mexico, Central and South America, Haiti, San Domingo, and the kingdom of Hawaii to send official delegates to the meeting of the Pan-American Medical Congress to be held in the City of Washington, September 5, 6, 7, and 8, A. D. 1893."

The Committee on Amendments to the Constitution and By-laws reported as follows: "The President is hereby requested to appoint a committee of five to whom the Code of Ethics of this Association shall be referred for such changes or amendments as they may deem wise to recommend, if they should decide that any change is required."

Dr. John B. Hamilton, of Chicago, delivered the Address in Surgery. He took for his subject the "General Principles of the Surgery of the Human Brain and its Envelops." He noted that although trephining had been employed from earliest times, and the dura mater had been incised by the older surgeons, the brain itself had seldom been touched.

He traced the various procedures that have been employed in operations upon the head. He could see no reason for the invention of the phrase, "cerebral localization," as the word "diagnosis" seems sufficient. The diagnosis of injuries, abscesses, and tumors of the brain, is more or less difficult, according to the extent of the injury. Lesions in certain situations are unattended

with symptoms upon which a diagnosis can be confidently made, so that the history and the complex of phenomena must be relied upon. Subdural abscesses frequently present negative symptoms. In the case of pistol-shot wounds of the brain, the difficulty of diagnosis is increased by the conflicting and perplexing character of the symptoms. Such a result is obvious, when it is reflected that, whatever the location of the missile at the time of the examination, the symptoms must likewise be those of the lesion occasioned by the passage of the bullet.

The diagnosis of lesions of the motor area, of the centers of articulate language, and of the sensory cortical centers, is now well defined, but that of lesions of the central ganglia is yet in an uncertain state. The motor cortical area has been subdivided into minute areas, each governing certain movements. The use of the ophthalmoscope in cerebral diagnosis has come to be essential. Optic neuritis and choked disc are found in most cases in which tumors are present. The size of the tumor does not seem to increase or diminish the intensity of the lesion of the optic nerve.

Oppenheim has recently observed rhythmic contractions of the veil of the palate and of the vocal bands, as well as of the muscles supplied by the inferior branches of the facial nerve, in association with lesions in the occipital fossæ. There were, besides, cephalalgia, dysphagia, vomiting, paresis, and contracture of one side of the face, without alteration of the electric reaction.

Benjamin Ward Richardson has proposed the practice of cranial auscultation as an aid to diagnosis in the study of intra-cranial disease.

Great progress has been made in the treatment of cerebral abscess. While in some cases the result of surgical interference is necessarily fatal, a number of cases have been reported in which the ultimate issue has been entirely successful. It is now acknowledged, even by the most conservative, that consecutive abscesses require additional trephining. In all cases of ethmoidal abscess, abscesses of the frontal sinuses and of the mastoid processes, the further extension of the disease should be prevented by free drainage.

In connection with cerebral injuries, the result most to be feared is the formation of an abscess, which may follow a fissure almost as readily as a fracture.

Ashhurst has recommended that in removing spicules or fragments of bone, in cases of fracture of the skull, the fragments should not be torn away with forceps, but, if necessary, carefully separated from the dura with the knife.

Wyeth has advised that if, in the case of a pistol-shot wound of the brain, the ball has passed beyond reach, the patient should be kept quiet long enough to allow the bullet to become encysted, as otherwise it might be displaced, from the slight resistance offered by the brain-substance. Numerous cases have been recorded in which operations upon the skull for fracture and for intra-cranial hemorrhage have been attended with successful results. The results from operation for the relief of cerebral tumor have not been so good. The subject of cerebral injuries in the newborn, due to pressure on the head in passing through the pelvis of the mother and to artificial delivery by the forceps, has received considerable attention, but the results of operative interference have thus far been negative.

Sufficient time has not yet elapsed to determine the ultimate value of the operation of craniotomy.

Mr. Tuke has recommended the operation of spinal laminectomy as the ideal surgical procedure for the relief of pressure due to intra-cranial collections of fluid.

In a number of cases, trephining has been performed in the hope of relieving mental disease. Trephining has also been performed in a number of cases of epilepsy, but the results are far from satisfying one as to the propriety of continuing the operation. It may be that by a careful selection of cases, and by the employment of the electric current when the convolutions are exposed, better results may be accomplished.

In a given case, a patient cannot be said to be cured until five years have elapsed after the operation. It has been admitted that traumatic epilepsy is practically incurable by surgical operation, and that a considerable number of such cases had better have been relegated to the domain of medicine. The view has been forcibly expressed that traumatic epilepsy should be prevented.

In Jacksonian epilepsy the presumption is against thorough cure as a result of operation.

The Nominating Committee recommends DR. HUNTER MCGUIRE, of Richmond, Va., for President, and Milwaukee as the next meeting-place.

SECTION ON SURGERY AND ANATOMY.

FIRST DAY—JUNE 7TH.

The Chairman, Dr. J. MCFADDEN GASTON, of Atlanta, Ga., read an address entitled "Surgery of the Gall-bladder and Ducts." (See p. 651.)

DR. W. H. MYERS, of Fort Wayne, Ind., read a paper entitled "Obstruction of the Cystic Duct, with a Case," in which he detailed the symptoms and effects of obstruction of the cystic duct. He called attention to the fact that for some reason, in some instances the gall-bladder undergoes immense dilatation, while in other instances it undergoes contraction. In the case reported, operation disclosed the presence of six calculi impacted in the cystic duct. After their removal a fistulous opening remained for several months.

DR. W. E. B. DAVIS, of Rome, Ga., read a paper on "Peritonitis from Gall-stones," in the course of which he stated that the bile is not a septic fluid, and consequently the inflammation to which it gives rise will be like that resulting from the irritation of any chemical agent. A limited quantity of bile that finds its way into the peritoneal cavity may be absorbed. If slowly exuded, it is confined by the protective adhesions that form, but the resultant irritation renders the peritoneum more susceptible to septic influences. Iodoform-gauze has proved useful as a means of draining bile from the abdominal cavity. Properly adjusted about the gall-bladder and the ducts, it will certainly protect the abdominal cavity from contamination. The danger of peritonitis as a complication of gall-stones is probably greater than one would be led to believe from experiments on animals.

In opening the discussion upon the three foregoing papers, DR. A. VANDER VEER, of Albany, N. Y., paid a high tribute of praise to the labors of Dr. Gaston. He reported a case in which an operation was performed for the relief of biliary calculi, with the removal of sixty-four

stones. He does not think surgical interference warranted until medical treatment has been exhausted. The operation of cholecystectomy should be approached with the greatest circumspection.

DR. H. O. MARCY, of Boston, presented three gall-stones removed from a patient operated on *in extremis* as a forlorn hope. Two of the calculi were found in the gall-bladder and one in the cystic duct. The patient recovered. Dr. Marcy does not deem it wise to defer operation too long in the hope that Nature will accomplish that which in our inner consciousness we realize she is unable to do.

DR. F. W. ROSS, of Toronto, stated that mere distention of the gall-bladder does not give rise to pain, while obstruction in the common duct is the more likely to do so. Patients are at times free from pain, although as a result of operation it becomes known that calculi have been present in the biliary channels for long periods of time. Dr. Ross likewise thinks it unwise to defer operation too long, as it has been demonstrated that the operation itself is not dangerous. He related a case in which a fistulous opening was made to close by applications of silver nitrate.

DR. CHRISTIAN FENGER, of Chicago, stated that he prefers cholecystotomy to cholecystectomy, if the former be sufficient to meet the indication.

DR. DUDLEY P. ALLEN, of Cleveland, reported a case in which the patient apparently died from the intensity of the pain.

DR. DAVIS stated that the point he wished to make was the safety of the employment of gauze, by means of which, in conjunction with the use of a drainage-tube, bile and septic fluids are diverted from the peritoneal cavity and permitted to escape, in this way avoiding the complication of peritonitis.

DR. JAMES T. JELKS, of Hot Springs, Arkansas, read a paper entitled "Gunshot Wound of the Liver and Stomach; Laparotomy; Recovery." The case was that of a young man about twenty-nine years old, with a bullet-wound three inches to the left of the spinal column in the dorsal region. He had vomited blood; his pulse was 70. Laparotomy was advised; at first declined, but finally consented to. The operation was performed under most unfavorable circumstances. On opening the abdominal cavity, a small quantity of blood was found, but no wound of the stomach could be discovered. A large bullet-hole was found on the posterior aspect of the liver, the bullet lying free in the abdominal cavity. After the removal of foreign matter, the abdominal cavity was cleansed, and a drainage-tube, wrapped with iodoform-gauze, was placed in the wound in the liver and permitted to remain for several days. The patient was for five days nourished by means of nutrient rectal enemata, and made a complete recovery, without complication, except for some abdominal distention as the result of accumulations of gas in the intestine.

DR. CHRISTIAN FENGER, of Chicago, expressed the view that the most important feature in connection with wounds of the liver is undoubtedly the hemorrhage, and this is probably best controlled by means of iodoform-gauze, as ligatures will not hold when applied to the hepatic parenchyma.

DR. GREGORY raised the question as to whether or not the operation was advisable, and expressed the view that many cases of the kind recover without operation.

DR. SAMUEL S. THORN, of Toledo, related a case in which, the patient died from loss of blood, although there was but a small laceration of the liver.

DR. J. B. MURDOCH, of Pittsburg, defended the operation on the ground that in cases of the kind reported, a surgeon could not feel that he had done his whole duty if he had not opened the abdominal cavity and assured himself of the condition of affairs.

DR. GREGORY stated that he did not wish to be understood as having objected to the operation, and thought that he might have been betrayed into its performance and subsequently not have regretted his action. He thought, however, that were the bullet left behind, it would have done less harm than the operation.

DR. JNO. H. MCINTYRE, of St. Louis, thought that a ball rolling about in the abdominal cavity would not be likely to become encysted and was better removed.

DR. JENKS maintained that if any other surgeon had been sent for in the case he would most likely have made a diagnosis of gunshot wound of the stomach. In that case it would have been his duty to have advised an operation, and if this were acceded to, it must have been done. Statistics show that death takes place in 63 per cent. of cases in which the liver is wounded.

DR. B. S. CAMPBELL, of Detroit, read a report of "Eight Cases of Esophageal Stricture," in the course of which he stated that until recently galvanism as a therapeutic procedure has been considered dangerous when applied to the esophagus, but rapid strides in this direction have been made, and numerous successful cases from the employment of electrolysis have lately been reported. Dr. Campbell reported at length the histories of eight cases satisfactorily treated by means of galvanism. He had never been able to obtain permanently good results in organic stricture treated by this method. He does not consider forcible dilatation a commendable procedure, as the irritation to which it may give rise often does more harm than good. Internal esophagotomy would be safer if the seat of stricture would be accurately located.

DR. ROBERT NEWMAN, of New York, expressed the view that strictures of the esophagus are caused, as a rule, either by the swallowing of strong acids or alkalies, or by malignant disease. Nothing of which he had heard had, to his knowledge, ever cured a stricture of the esophagus except electrolysis.

DR. J. D. GRIFFITH, of Kansas City, expressed a desire to know if Dr. Campbell had ever employed electrolysis in children. He had himself seen several such cases, in one of which the narrowing resulted from the swallowing of concentrated lye. In this case he had found operation exceedingly difficult, owing to the struggles of the patient.

In reply, DR. CAMPBELL stated that he had seen but one case in a child, and in that electrolysis had not been employed.

SECOND DAY—JUNE 8TH.

Morning Session.

DR. DUDLEY P. ALLEN, of Cleveland, read a paper entitled "The Late Manifestations of Appendicitis and their Treatment." A consideration of the primary mani-

festations of appendicitis was not presented on account of the full consideration that such cases have received. For the purpose of illustrating the subject, six cases were selected presenting various manifestations of the disease. The first case was that of a young man who had suffered from repeated attacks of what he supposed to be colic; the attack that led to the operation had not, in its beginning, differed from preceding attacks. After a few days, however, a well-marked abscess developed in the region of the cecum; this was opened and the appendix removed. The second case was that of a woman who, in a period of twelve days, developed an abscess occupying the right lumbar region, extending from the ribs to Poupart's ligament, and containing perhaps two quarts of pus, with masses of gangrenous tissue. The third case was that of a man who developed an abscess located in the region of the cecum, for which he was operated upon, and from which he seemingly recovered. A few months later, an abundant dischage of pus, having the appearance and color of anchovy sauce, took place from the lung; this discharge, together with the results obtained on percussion, rendered it probable that an abscess had been developed in the liver and was emptying itself through one of the bronchi. The fourth case was that of a young man who had suffered from repeated attacks of pain in the region of the cecum during twelve years. A slight point of induration was discovered in the right iliac region. Operation was performed, to the entire relief of the patient, although a small fistula still remained. The fifth case was that of a young man who, five months previously had had an attack of appendicitis. Though no abscess had developed, so far as had been observed, there was some induration in the right side of the abdomen, and the patient was strongly bent over to the right side, the evidence being that the psoas muscle of that side was involved in the inflammatory process. The case was operated on and a small concretion was removed; the patient recovered. The sixth case was one in which the diagnosis of appendicitis was made, and the patient was removed to the hospital for the purpose of consultation and operation. A cessation of the pain threw the diagnosis into doubt, and no operation was performed. Some dulness at the base of the right lung developed, together with profuse expectoration, and the suspicion arose that the difficulty was tuberculous. Later, however, abscesses formed in the right thigh, and after a thorough study of the case it became evident that it had primarily been one of appendicitis.

Dr. Allen advocated that in recurrent cases of the sort mentioned, operation should be performed for their relief; while recognizing the dangers of such operations, which must at times open the abdominal cavity, it was held that the danger of operation was vastly less than that of delay. The advantages of the extra-peritoneal method of operation were discussed, as compared with methods in which the abdominal cavity was opened; while the advantages of the former are great, there are certain cases in which the point of disease could be reached by no method but the trans-peritoneal. While one hesitated as to operating upon a case of perityphlitis in the quiescent condition, it was held that should the disease frequently recur the dangers of operation were less than those of delay.

DR. R. H. MUDD, of St. Louis, was absent and his paper on "Acute Intestinal Obstruction, and the Use of Saline Cathartics for Diagnostic Purposes," was read by title. He contended that in some cases of intestinal obstruction there is legitimate reason for the most skilled diagnostician to be in doubt.

The differential diagnosis ordinarily rests between colic, peritonitis, and obstruction. Laparotomy is accepted as the most reliable therapeutic measure for the relief of intestinal obstruction.

To be a useful therapeutic agent laparotomy must be performed early in the course of the obstruction. It was proposed that in doubtful cases saline cathartics be employed to establish a positive diagnosis in time to act efficiently and save the patient.

Saline cathartics purge cases of colic, which are then curable by a sedative; they may arrest peritonitis; they develop and make plain the more serious condition of mechanical obstruction. If given early in the case, the distress and aggravation of the symptoms that they occasion will subside under the use of morphine, and the general condition will then permit of operative relief.

It is only in cases in which the doubt is sufficiently strong to control action that the saline purgative is used. It should be given promptly. The time for its efficient administration is in the lull, or quiet, induced by the first dose of morphine. It may again arouse ineffective and painful peristalsis, but in many cases it will resolve doubt and determine surgical interference, when it is still possible to save the patient.

The decision is to be made whether, in a doubtful case, presented within forty-eight hours of the onset of the trouble, the surgeon should wait and let time resolve the doubt and destroy the patient, or if an exploratory laparotomy is to be performed on a patient who does not need it. The purgative may afford the third and safest method of solving the doubt.

DR. NICHOLAS SENN, of Chicago, presented "A Clinical Contribution to the Operative Treatment of Acute Intestinal Obstruction," which he stated he desired to make a sequence of the papers on the "Surgery of the Gall-bladder and Ducts," read on the previous day. He contended that it is not always as easy to determine that the biliary apparatus is affected as the papers previously read might lead one to believe. Dr. Senn related a case presenting all of the appearances of chronic gastric catarrh, with dilatation of the stomach. Very careful examination raised a doubt that the case was one of pyloric stenosis, due to cicatricial contraction. When a median laparotomy was performed, enormously firm adhesions were found in the vicinity of the pylorus, but no evidence of cicatricial contraction of the stomach. The walls of the gall-bladder were thickened and the viscus was imbedded in cicatricial tissue. Examination detected a gall-stone, about the size of a walnut. This was removed and the patient recovered with immediate relief of the gastric symptoms.

In another case, the patient had suffered for several years with symptoms that might have been construed as indicative of the presence of gall-stones. On operation, the intestines were found enormously distended and congested and containing a gall-stone twenty inches above the ileo-cecal valve. Dr. Senn expressed the belief that large gall-stones seldom or never reach the intestine

through the duct, but that they ulcerated their way through from the gall-bladder to the intestine. In the last two years he has operated upon four cases of dermoid tumor of the abdominal wall. All of the cases were in women that had borne children. These tumors resemble fibromata, but microscopically present, besides, some of the elements of sarcomata. A large tumor was exhibited that had only been noticed four months before operation, its rapid growth indicating its malignancy. Dr. Senn called attention to the differential diagnosis between intra-mural and extra-mural tumors. The former are, as a rule, covered by nothing but the skin and the fatty cushion under the skin. One of the great difficulties in removing these dermoid tumors resides in the intimate attachment of the peritoneum to the tumor. As the result of operation, a large gap is left in the abdominal wall, the muscles of which have already been atrophied by the pressure of the tumor. Dr. Senn therefore utilizes the omentum and borrows from the adjoining muscles on account of the great difficulty of closing the opening.

DR. JOSEPH PRICE, of Philadelphia, read a paper on "Intestinal Lesions in Abdominal Surgery," which is to appear in a subsequent number of THE MEDICAL NEWS.

DR. GREGORY made a motion that the references to Dr. Mundé contained therein be expunged. This called forth a heated discussion.

DR. PRICE maintained that all published writings are on record and are for public use.

DR. L. S. MCMURTRY said that he did not think any discourtesy was intended to Dr. Mundé, and he thought the motion of Dr. Gregory would be construed as a criticism of Dr. Price.

DR. BISHOP expressed the opinion that, if carried, such a motion as Dr. Gregory's would considerably impair the usefulness of the American Medical Association.

DR. PRICE re-read the portion of his paper referring to Dr. Mundé, and after some further discussion Dr. Gregory's motion was voted upon and lost.

Afternoon Session.

DR. J. M. MATHEWS, of Louisville, had neglected to bring his paper on "The Comparative Merits of Inguinal and Lumbar Colotomy" with him, but made a few remarks from memory. While the inguinal operation has largely supplanted the lumbar, he preferred the latter. The advocates of the inguinal method claimed that it is the more easily performed. If this is true, we should prefer it; but do statistics show this? Looked at in an anatomic light, it does not seem any simpler. The lumbar operation is extra-peritoneal and the inguinal intra-peritoneal, though it is claimed that in the former we cut into the peritoneum oftener than we think. Some would claim that going into the peritoneum is little to be feared. Granting that, if two operations will give the same results, one with and the other without entering the peritoneal cavity, is not the latter preferable? Secondly, in performing the operation in the iliac region, we are dealing with a diseased condition; we are cutting into the peritoneum for carcinoma of the rectum or sigmoid flexure. Thirdly, in some cases the mesentery here is very short and we cannot accomplish the operation we started out to do. In performing the lumbar operation, this is not the case. Carcinoma of the sigmoid flexure may exist and progress to a fatal issue without a positive diagnosis having been made.

DR. J. D. S. DAVIS, of Birmingham, Ala., was absent and his paper on "A Comparative Test of Anastomotic Devices," was read by title.

DR. J. SCHNECK, of Mt. Carmel, Ill., read a paper on "The Treatment of Injuries of the Abdomen not requiring Surgical Operations." He divided the abdominal injuries not requiring surgical interference into two classes: those involving the parietes only and those in which the integument is unbroken, but some of the internal viscera are injured. The most serious effects may follow even what seem to be simple injuries of the abdomen. One of the great sources of danger is shock following injury to the nerves of the cavity. Injuries above the umbilicus are more fatal than those below. As the surgeon usually finds the patient in a state of depression and shock, immediate means of relief should be employed. This is often and quickly accomplished by rectal injections of hot water, with the twofold idea of emptying the bowel and acting on the solar plexus. Several cases illustrating the efficacy of the treatment outlined were related. Dr. Schneck thinks that all injuries of the abdomen should be considered very serious and a guarded prognosis given.

DR. MORDECAI PRICE, of Philadelphia, and DR. JOHN WYETH, of New York, were absent. Their papers, on "Emergency Work in Abdominal Surgery," and "The Present Status of the Surgery of the Vermiform Appendix," respectively, were read by title.

DR. W. B. DEGARMO, of New York, read a paper entitled "A Few Points on the Management of Strangulated Hernia." He stated that the death-rate from strangulated hernia has not diminished as it should have done in the face of modern surgery, owing probably to a fear of touching anything relating to the peritoneal cavity. The object of the paper was to emphasize a few points and to dissipate some false ideas as to the management of these cases. Many a sufferer from strangulation has been sacrificed to the hypodermatic needle. Much valuable time may be lost in trying different remedies, and more harm done than good. Evidence is strong in favor of the local application of sulphuric ether, about a tablespoonful poured over the tumor every fifteen minutes; but this treatment should not be continued for too long a time. The great difficulty is to decide when to operate; undoubtedly many lives are sacrificed by delay. Amputation of the omentum adds much to the danger: first, from secondary hemorrhage; secondly, from sepsis. Careful ligature of the vessels of the omental stump will obviate the first, and the second is no longer very important to careful operators.

DR. JOS. RANSOHOFF, of Cincinnati, read an interesting and valuable paper on the "Management of Gangrenous Hernia, with Report of Four Cases," in one of which fourteen inches of the gut was removed, primary union and uninterrupted recovery following.

DR. H. O. MARCY, of Boston, opened the discussion by paying a high compliment to Dr. Ransohoff. Sometimes he thought that we had too many operators, or rather too many attempting to operate who had not had the proper training. He thought it a part of every physician's duty to know how to operate on a strangu-

lated hernia. He considered inguinal hernia in the male as the most difficult of treatment and cure. Three centuries ago these hernias were cured by sacrificing the testicle. At the present day, by careful operating, we are able to obviate the necessity of drainage and to seal the wound with iodoform-gauze; and if the wound is aseptic, we may be assured that it will remain so. This is a great advantage in operations on children, who soon soil the ordinary dressings.

DR. D. A. WATSON, of Jersey City, discussed the papers read in the morning, advocating conservative and aseptic surgery.

The following were elected officers of the Section for the ensuing year: Dr. James T. Jelks, of Hot Springs, Ark., *President;* Dr. Ernest T. Tappey, of Detroit, Mich., *Vice-President;* and Dr. Montgomery, of Chicago, *Secretary.*

SECTION ON PRACTICE OF MEDICINE.

FIRST DAY—JUNE 7TH.

In the absence of the Chairman, DR. ROBERT T. EDES, of Jamaica Plains, Mass., DR. ATKINSON, of Baltimore, was unanimously chosen Chairman *pro tempore.* The address of DR. EDES on "The Relations of Bacterio-chemical Results to Prophylaxis and Therapeutics" was read by DR. GERRY. He endeavored to show that bacteriology gives a more clear definition of many facts heretofore vaguely and indistinctly recognized. Two kinds of immunity to infectious disease can be recognized. The one is specific, like that conferred by one attack of an exanthem to another attack of the same kind, or that conferred by vaccinia to variola, or in the lower animals conferred by certain artificially attenuated poisons to the natural infection. The second form of immunity is general, and is attained by improving the nutrition of the blood (solid tissues?), possibly by making the leukocytes stronger.

Bacteriology imposes new duties, without diminishing the old. In tuberculosis, for instance, since we cannot as yet (in spite of the admirable work of Koch) confer specific immunity, we must endeavor to produce the greatest possible degree of general immunity by bringing the nutrition to its highest point, and to prevent infection by the avoidance of impure air and all tuberculous contact. Specific therapeusis by means of drugs is not in a much more hopeful condition now than it was before the doctrine of auto-intoxication had become so prominent, and covered so much ground.

Quinine and the salicylates, however, still remain as types of specific medication. The old clinical reputation of quinine has been upheld and fortified by the observation of the disappearance of specific malarial organisms under its use.

The increase in opportunities for laboratory work in biology in this country is a matter for congratulation, and the desirability of the clinician setting as high a standard as possible for accurate observation must be insisted on.

In the discussion, Dr. D. E. KINSMAN, of Columbus, Ohio, referred to the vital interest surrounding the subject of immunity. He dwelt upon the difference between immunity and absolute protection. The latter is perhaps not attainable. He detailed experiments that he had carried out, showing that comparative immunity is attainable, and that attenuation to one-sixth of the original strength could be secured by successive cultivation in urine of the bacilli of hog-cholera.

DR. W. J. SCOTT, of Cleveland, Ohio, stated that it is of importance to ascertain whether it is the bacillus or its products that are employed in experiments.

DR. CHARLES DENISON, of Denver, Col., expressed regret that Dr. Edes implied that tuberculin as a therapeutic agent is a failure, because in a letter recently received, Dr. Edes expressed his great faith in the remedy. From his own use of it, during the past fifteen months, Dr. Denison believes that it will prove brilliantly successful. As a result of his experience he has determined some of the rules and limitations for its employment, the observance of which will render the use of tuberculin practically safe. It must be borne in mind that there is in the human system something antagonistic to such poisons as that of tetanus, diphtheria, typhus, etc.

DR. S. P. KRAMER, of Cincinnati, stated that in the production of immunity, two methods have been principally pursued. The one is that of the employment of attenuated cultures, as developed by Chauveau and Pasteur. The second is the method by which an albumin derived from the body of the germ is utilized. This, when brought in contact with certain principles contained within the animal organism, produces a body that neutralizes the toxic principle and reduces the pathogenic germ to the level of an ordinary saprophytic germ. In the first form, the antitoxin is formed by the growth of the germ within the body; in the second by the growth of the germ in the test-tube. The first method, which may be called serum-therapy, has been credited with the cure of six cases of tetanus.

DR. R. FRENCH STONE, of Indianapolis, read a paper on the "Etiology of Specific Disease." Less than twenty-five diseases, he stated, are classed as specific. The proximate causes are not known. He described the condition of the body that facilitates the entrance of infectious agents, particularly the state of the alimentary canal. There are numerous theories as to the cause of specific disease. Beale's view of infection by transplantation of diseased bioplasm contains an element of truth. All infective agents require an excess of nitrogenous matter in the blood. The microphyte theory may be regarded as the correct one.

DR. S. P. KRAMER, of Cincinnati, read a report of "Recent Investigations of the Etiology of Diabetes Mellitus." He stated that, according to Senator, a pathologic change in the pancreas occurs in about half of the cases of diabetes mellitus. Complete excision of the pancreas has invariably been followed by the development of true diabetes mellitus. Partial obliteration, however, is not attended with the same result. Bull has reported a case confirmatory of this view. It has been found that transplantation of pieces of pancreas in dogs that have been subjected to excision of the pancreas prevented the development of diabetes. Dr. Kramer arrives at the conclusion that in the normal condition, the pancreas gives rise to the production of a principle, as a result of the circulation of which in the general blood-current the dextrose absorbed is so modified that its combustion within the organism is rendered possible. With the removal of the function of the pancreas, this

change does not take place. The sugar is not utilized, but is eliminated in the urine.

DR. GEO. E. FELL, of Cincinnati, stated that in a case of abscess of the liver the patient had diabetes until the abscess ruptured, but the glycosuria ceased with the evacuation of the abscess into the bowel.

DR. S. SOLIS-COHEN, of Philadelphia, referred to the subdivision by Lancereaux of diabetics into thin and fat. In the lean cases lesions of the pancreas are commonly found; but not in the fat cases. Cases are, however, found in families, some members of which have gout, others diabetes, and still others pulmonary tuberculosis.

DR. JOHN E. LINK, of Terre Haute, Ind., read a paper on "La Grippe," in which he expressed the view that influenza is dependent upon a depressing influence that acts especially upon the central cells of the medulla, and possibly also upon those of the cord. The pneumonia that is so commonly present as a complication is not a true lobar inflammation, but rather a congestion, of nervous origin. The continuous coughing is not the cause of the vomiting. The process seems rather to be a paresis of the pneumogastric nerve and of the sympathetic system. The heart and other viscera are affected in a like manner. A case of acute edema of the lungs in a patient suffering from influenza was referred to. Dr. Link stated that he had carefully observed a number of similar cases. In another case of influenza, acute tachycardia developed, the pulse rising in frequency to 200 beats in a minute.

DR. JOHN H. HOLLISTER, of Chicago, Ill., read a paper entitled "A Modified Form of Continued Fever following the Epidemic La Grippe." He stated that in the month of May, 1891, he had in a considerable number of cases observed a type of continued fever that was not confined to a special class or locality, and for which no cause could be determined. By August the manifestation had disappeared. It was suggestive of typhoid fever, from which it differed, however, in many important respects. An analysis of fifty cases showed that the prodromata lasted from one to four days. Extreme muscular soreness was the symptom most commonly complained of. The onset was gradual and without chill. The average duration of the disease was twenty-three and one-quarter days. The temperature range was high and continuous. There was usually but a moderate demand for liquids. Nervous symptoms were not conspicuous, except for the depression. The mind was not disturbed. There was neither subsultus nor other symptom of ataxic typhoid fever. In four cases there was profuse perspiration. The digestive system showed little disturbance. The tongue was not brown or dry. The dorsum was clean and white as though brushed with white paint. Emaciation was rapid. Epigastric pain was only moderate. There was no peritonitis. The bowels were usually constipated. Typhoid bacilli were not found in the stools. There was a notable tendency to relapse, generally induced by indiscretion in diet. Only three cases terminated fatally: one from pneumonia, and two from exhaustion. There were no intestinal lesions. The urinary color-test of Ehrlich was not employed. Eruptions were absent. The face was strikingly pallid, instead of presenting the dull, heavy aspect of typhoid fever.

DR. HEMENWAY, of Illinois, expressed the opinion that influenza primarily presented the manifestations of an intoxication, probably dependent upon microbic invasion, and that the nervous manifestations represented the effects of the poison. Only in this way can the fatty degeneration of the heart be explained. In the cases reported, the fever must be attributed to the activity of some ptomaïne. Dr. Hemenway had found that if an energetic dose of calomel was administered, there was rarely occasion to see the patient twice. Fever is most likely to be kept up in patients that have taken antipyretics, particularly acetanilide.

DR. N. S. DAVIS, of Chicago, expressed the view that the manifestations of the disease were those of one of nervous origin. He regards the disease as contagious.

SECOND DAY—JUNE 8TH.

Morning Session.

DR. BEDFORD BROWN, of Alexandria, Va., read a paper entitled "Positive and Negative Medication." He stated that in the administration of remedies the effect must be positive or negative, the results good or bad. To secure the proper effects, the solubility of medicine must be considered. The pill is the most insoluble of pharmaceutic preparations; stale sugar-coated pills are the worst. The best excipient is glycerin. In cases of high temperature the stomach loses its power to dissolve pills, and solutions only should be given. This refers especially to the administration of quinine in malarial fevers. The cool bath promotes the preservation of the digestive functions. Dr. Brown illustrated by cases the incapacity of the stomach in certain diseased conditions even to digest food; hence, in such cases the effects of pills given would be negative. Again, negative results are owing to adulteration of drugs. For this physicians are in part responsible, by purchasing poor drugs because they are cheap. A third cause of negative results is the use of vaunted but valueless patent medicines in uterine diseases. Further, it is important that infusions should be properly made from the fresh drug, and not from stale extracts.

DR. DIDAMA, of New York, stated that he thought that the use of the tablet-triturates was generally followed by good results. Powders in wafer are also readily dissolved.

DR. WILSON, of Kansas City, stated that negative results in medication are often of value in teaching the physician that success lies in the dispensing of one's own medicines.

DR. HERRICK, of Cleveland, stated that the dispensation of one's own remedies is the proper procedure. It not only leads to surer results, but it tends to overcome the unpalatability of remedies.

DR. H. J. HERRICK, of Cleveland, read a paper on "The Relative Interdependence of Organs in Health and Disease." He has arranged the organs in three groups, according to their mutual dependence. The first group consists of osseous, connective, and cellular tissues. The second group consists of the circulatory, muscular, nervous, and reproductive systems. The third group consists of the organs of secretion, digestion, absorption, assimilation, and excretion. Dr. Herrick regards the organs of the third group as the first in the order of

those that are essential to the health of the others. He thinks that if the food could be adjusted to the special requirements of the case, a large part of the disease of the world could be eliminated. All medication should be directed to the regulation of the physiologic processes. As yet antidotes to specific diseases are undiscovered, but there is in the human body itself, in the white blood-cell, in the spleen and liver, an agency destructive of noxious agents. Hence attention should be directed to these organs and not solely to the exclusion of germs from the body.

DR. E. P. GERRY, of Jamaica Plains, Mass., read a "Report of a Case of Amebic Dysentery." He took occasion to say that the specific ameba is the ameba dysenteriæ—not the ameba coli. It causes a special disease, a special form of dysentery. An illustrative case was described in detail.

DR. J. H. MUSSER, of Philadelphia, stated that he was especially interested to learn that this form of dysentery should occur so far north, although Councilman has reported a case occurring in Canada.

DR. WALTER S. CHRISTOPHER, of Chicago, read a paper on "Retained Feces." He stated that recent investigations in France indicate that the ameba coli commune is responsible for cases of appendicitis and perityphlitic abscess. Destruction of noxious substances in the liver in many cases prevents the development of stercoremia. The symptoms of this condition are usually headache and depression. An ordinary bilious attack is commonly a result; so may anemia or fever be a result. Cases illustrating the phases of disease caused by the absorption of poisonous substances due to retained feces were related. A case of Dr. Moyer's, in which confusional insanity was attributed to stercoremia, was detailed at length. Recovery followed repeated rectal injections. An important matter in treatment is that rectal injections must be repeated, sometimes for weeks.

DR. N. S. DAVIS, JR., of Chicago, called attention to the fact that feces may be retained, though the bowels move daily. The most common symptoms are mental depression, backache, and some anemia.

DR. FULLER, of Massachusetts, referred to a case in which repeated attacks of retained feces were found after death to be associated with contractions of the colon.

DR. NEWCOMB, of New York, referred to a fatal case of supposed acute meningitis, in which no post-mortem explanation could be offered for the symptoms except a colon distended with feces.

DR. J. M. ANDERS, of Philadelphia, thought that in a certain number of cases a catarrhal condition was developed from the constipation, and the catarrh becomes responsible for the anemia.

DR. S. SOLIS-COHEN, of Philadelphia, referred to a case of laryngeal ulceration, in which a diagnosis of stercoremia was made, and treatment resulted in cure. In another case a diagnosis of pneumonia had been made, but the condition was one of retained feces. Again, renal colic has been mistaken for retained feces.

DR. CHRISTOPHER, in closing the discussion, called attention to the fact that hot-water injections have proved very soothing and have given more relief than other remedies in renal and intestinal colic.

Afternoon Session.

DR. LEWIS M. DAVIS read a paper entitled "Transmission and Behavior of Typhoid Poison as Observed in Country Practice." He expressed the belief that water is the common vehicle of transmission of the typhoid poison, but he thinks that the infection is also carried by the air. The disease is contagious. In illustration of this statement, he reported a local epidemic of fourteen cases that developed in those that nursed or were in attendance upon the first case. The infection in the first case occurred at a point distant from that at which the epidemic occurred.

DR. CHAPLIN, of Michigan, reported a similar set of cases of typhoid fever.

DR. J. H. MUSSER, of Philadelphia, stated that the relations of the first with the subsequent cases should be marked out. In the Plymouth epidemic infection occurred by percolation of the feces of the first case into the water-supply at the head of the stream.

DR. HAROLD N. MOYER, of Chicago, read a paper on "Catarrhal Gastritis." (See p. 645.)

DR. STOCKTON, of Buffalo, stated that the subject of lavage is largely misapprehended. Its value is greater in diagnosis than in treatment. The question must be settled first whether or not there is excess of hydrochloric acid. Before this question is decided a suitable diet cannot be recommended. Hence the tube is most valuable as an aid in diagnosis and as an indication of the diet to be prescribed.

DR. DALAND stated that frequently in these cases of chronic catarrhal gastritis there is at least apparently complete absence of hydrochloric acid. The tube is a more valuable adjunct than it is at present believed to be.

DR. SCOTT, of Cleveland, stated that he had used the stomach-tube with advantage. Hyperacidity may depend upon an excess of hydrochloric acid or of acetic acid. Anti-ferments will do more good than pepsin if the excess of acidity be the result of fermentation. By the use of the tube one is enabled to make an accurate diagnosis, and to adopt suitable treatment.

DR. PORTER, of Michigan, called attention to the great frequency of gastritis, and predicted that in the near future we shall have special departments devoted to diseases of the stomach. Diet is of more value in the treatment than all medicines.

DR. H. A. HARE, of Philadelphia, called attention to the utility of pepsin and soda, the soda in these cases stimulating the stomach to increased secretion of gastric juice. In the ordinary prescriptions of pepsin and hydrochloric acid, too little of the latter is used. In the majority of cases tonics do more harm than good. The stomach is of less importance than the intestine. Upper-bowel digestion will be facilitated if food is given that will pass readily into the intestine from the stomach. How often should lavage be used? No one can appreciate its disagreeable effects who has not tried it on himself.

DR. N. S. DAVIS, JR., of Chicago, stated that most cases of gastritis are associated with muscular weakness of the organ. Respiratory exercises, such as promote oxygenation of tissue, are healthful; so, also, are remedies to promote intestinal peristalsis.

DR. MOYER said the speakers had not confined themselves to the subject. He had limited his paper to a consideration of the treatment of uncomplicated catarrhal gastritis.

DR. ARCHIBALD CHURCH, of Chicago, read a paper on "The Vertigo of Arterio-sclerosis," which is to appear in a subsequent number of THE MEDICAL NEWS.

In the discussion, DR. W. G. SCOTT, of Cleveland, asked if nitro-glycerin had been found beneficial.

DR. CHURCH replied that its effects had been disappointing.

Dr. N. S. DAVIS, JR., of Chicago, read a paper on "Some Non-valvular Heart-murmurs." He defined as non-valvular heart-murmurs such as are produced in the absence of lesions of the valves. A case was detailed in which a systolic apex-murmur was associated with great dyspnea and chronic nephritis. Embolism of the right arm occurred. At the autopsy, the lesions of chronic nephritis were found. An old clot was adherent to the chordæ tendineæ, preventing accurate closure of the mitral valve. Another case of non-valvular murmur due to heart-clot, and caused by nephritis, was reported. There was, in this case, first a double systolic murmur, and subsequently a single murmur. At the autopsy, there was a dull-white clot in the right ventricle, entwined in the chordæ tendineæ and extending into the pulmonary artery. In a third case, there was a soft apex systolic murmur and dilatation of the heart, with moderate bronchitis. After a long interval, during part of which some improvement took place, the patient grew worse and died. At the autopsy, the valves were found to be normal, but there was chronic pericarditis with a calcified plaque on the pericardium.

DR. O. B. CAMPBELL, of Ovid, Mich., read a paper on "The Importance of Position in Examination for Diseases of the Heart." He stated that all murmurs are louder when the patient is in the recumbent position. This rule holds good in ninety per cent. of cases.

DR. NEWCOMBE, of New York, stated that as an examiner for an industrial insurance company he has met with a number of cases of non-valvular murmurs due to an increased action of the heart.

DR. KENNEDY, of Michigan, stated that in examining boys for the navy, he had discovered murmurs that could not be accounted for except on the theory that they were due to cigarette-smoking. In some cases he had discovered murmurs in the recumbent position which were not audible when the patient was standing.

DR. COUCH, of Kentucky, read a paper on "The Relation of Nutrition to Pathology," in which he expressed the opinion that disease is a process of abnormal nutrition.

SECTION ON OBSTETRICS AND DISEASES OF WOMEN.

FIRST DAY—JUNE 7TH.

The Chairman, DR. E. E. MONTGOMERY, of Philadelphia, read an address entitled "Some Mooted Points in Obstetrics and Gynecology." (See p. 654.)

DR. T. RIDGWAY BARKER read a paper on "The Relation of the Duration of Gestation to Legitimate Birth." He dwelt especially upon the uncertainty of the duration of gestation. Since fertilization of the ovule is not coincident with insemination, the matter of calculating the date of confinement must necessarily remain uncertain. The variability in the length of the period of gestation is not due simply to the difference in time between conception and the cessation of menstruation, but depends to a considerable degree upon the rapidity of embryonic development. One continually meets women who have been delivered of mature infants after carrying them for only 242 days, while in the case of others the period has lasted some 323 days. The opinion of Duncan, that prolonged gestation was denoted by unduly advanced intra-uterine growth and development, is not tenable, since the rapidity of cell-proliferation is subject to wide differences. To base, therefore, a diagnosis of legitimacy or illegitimacy upon the presence or absence of these changes could not be otherwise than fallacious.

Dr. Barker reported forty-two cases of legitimate gestation marked by great brevity or unusual length. Among these there were three sets of twins—first, two females, gestation lasting 275 days; secondly, male and female, at 265 days; and, thirdly, two females, at 242 days.

The age of the mother seemed to have no determining effect upon the length of the period; for of the forty-two cases, seventeen were over thirty years old and twenty-five under. Of the total number, twenty-seven cases were marked by brevity, the gestation varying from 242 to 274 days, while in the remainder the period lasted from 289 to 323 days. There were twelve cases between 290 and 323 days, and six cases over 300 days. The youngest primipara was fifteen years old; the oldest, fifty-one years old. Of the primiparæ, five had long periods and nine short periods. The minimum was 255 days; the maximum, 323 days. In fifteen cases the placenta was normal; in the others being battledore.

There seems to be a tendency for a certain number of days to repeat themselves; thus, between 254 and 267 there were nineteen cases; furthermore, four of this group were confined on the 265th day, four on the 266th, and two on the 307th day. In considering these great variations in the duration of gestation, can we do otherwise than agree with Jaggard in saying that "the real duration of pregnancy is an unknown quantity?" The question of legitimacy is not to be decided solely by the length of gestation, nor by the size, weight, or development of the fetus, but should represent "the sum of all the circumstances having a direct bearing upon the case."

DR. WILLIAM B. DEWEES, of Salina, Kansas, read a paper entitled "A New Axis-traction Obstetrical Forceps."

The following conclusions were arrived at:

With the patient placed in the left lateral (English) position, obliquely across the bed, with the nates brought to its edge, and by the use of this forceps it is plain:

1. That axis-traction is made perfect, easy, and simple. 2. That axis-traction at the superior strait is perfect and so continues during the entire passage of the fetal head, following the curve of Carus, from the brim to the outlet, with ease and safety. 3. That the axis of the blades of the forceps lies constantly parallel with the axis of the parturient canal as the head descends, thus enabling the accoucheur to fulfil a most important aim in forceps-operations, namely, to deliver with a

minimum amount of force. 4. That the operator is enabled to seize the head more advantageously at the brim; the facility with which the head can be aided to descend in the axis of the superior strait, as well as to follow the axis of the pelvis, would seem scarcely possible to one accustomed to the ordinary forceps. 5. That it is easy of application, and in its triple character, having a moderate head curve, a moderate pelvic curve, and a decided perineal curve (the latter is provided in the handles, which serve for traction), it has all the advantages of axis-traction, with plenty of power and perfect control and with the simplicity of the ordinary forceps. 6. That it does away with the complicated, cumbersome, and expensive attachments of the Tarnier and other models. The indicator is constantly in the sentient hands of the operator, who thus at every moment knows through his *conscience musculaire*, the direction of traction as well as the resistance, thus preserving intelligent observation of the progress of labor, and regulation of the forces employed, which alone can be done by the use of the hands in executing traction and extraction.

DR. JOHN MILTON DUFF, of Pittsburg, read a "Report of Cases of Albuminuria of Pregnancy Treated by Chloroform Internally." His conclusions were that, while the drug increases the flow of urine and causes a diminution in the amount of albumin, its effect is not constant. In some cases, it rather aggravates the condition. It is of benefit, however, in warding off eclampsia.

DR. EDWARD P. DAVIS, of Philadelphia, read a paper on "The Treatment of Posterior Rotation of the Occiput During Labor," which is to appear in a subsequent number of THE MEDICAL NEWS.

SECOND DAY—JUNE 8TH.

Morning Session.

DR. G. I. MCKELWAY, of Philadelphia, read a paper on "Delivery through the Abdominal Walls in Otherwise Impossible Births," which is to appear in a subsequent number of THE MEDICAL NEWS.

In the discussion, DR. E. P. DAVIS, of Philadelphia, urged the importance of diagnosis early in cases of contracted pelvis. He has recently been compelled to perform craniotomy in three cases on account of the neglect of the attending physicians, because of ignorance. He advised craniotomy on living monsters, because hydrocephalic children are often lacking in development in other respects, so that life is impossible or undesirable. He reported an illustrative case.

DR. W. E. ASHTON, of Philadelphia, stated that he would perform Cæsarean section only upon the patient's request. Abdominal operations are dangerous. The induction of premature labor is preferable.

DR. NEWMAN, DR. REED, and DR. WATHEN denounced craniotomy on the living fetus.

DR. ROHÉ urged discrimination in cases.

DR. JENKS advised total extirpation of the uterus in complicated cases.

DR. LAPTHORN SMITH agreed with Dr. Jenks. He would induce labor when possible.

DR. C. HENRI LEONARD, of Detroit, presented a paper entitled "Impairment of the Voice in Female Singers Due to Diseased Sexual Organs." The subject is one to which attention has not been generally called. Female singers have noted a huskiness of the voice at the menstrual periods, and in some cases in which the voice had been failing, the relief of a derangement of the generative apparatus has been followed by improvement in vocal power. The mechanism is probably by an inhibitory influence transmitted from the hypogastric plexus to the pneumogastric, the spinal accessory, the recurrent laryngeal and glossopharyngeal nerves.

The paper of DR. AUGUSTUS P. CLARKE, of Cambridge, Mass., on "The Importance of Surgical Treatment for Laceration of the Cervix Uteri," was read by title.

DR. ELY VAN DE WARKER, of Syracuse, N. Y., read a paper on "Hysterical Mania as a Complication of Gynecological Cases," the full text of which is to be published in the *American Journal of the Medical Sciences*.

He urged proper gynecologic attendance for insane women, stating that 10 per cent. of such inmates of asylums could be improved or cured by suitable gynecologic treatment. Asylum physicians are not usually competent gynecologists. Melancholia is the form of mental trouble most common in diseased women. It is not dangerous to life; few become permanently insane. The hysterical type of dementia is troublesome and persistent. The patient may cause trouble by refusing food after operation. The cases are difficult to influence and are trying for nurses. Traumatic mania may follow etherization and operation. It is not often observed after operation without ether. Such patients cannot be legally controlled in general hospitals, hence restraint by hospital physicians is necessary, although illegal. Dr. Van de Warker urged the appointment of properly qualified men as asylum physicians.

DR. GEORGE H. ROHÉ, of Catonsville, Md., read a paper upon "The Influence of Parturient Lesions of the Uterus and Vagina in the Causation of Puerperal Insanity." Four cases were reported, in each of which there were rupture of the perineum, laceration of the cervix, and morbid conditions of the ovaries and tubes. In all, laparotomy had been performed and the uterine appendages removed. Two of the cases, one of ten weeks' and the other of eighteen months' duration, recovered their normal mental condition after the operation. The other two cases, both of five years' duration, and in a condition of partial dementia, were much improved. The cases are held to justify the following conclusions:

1. Puerperal insanity is, in at least the majority of cases, an infection-psychosis.

2. Without rejecting the influence of other factors, such as heredity, anemia, exhaustion, mental shock and distress, careful observation will show that few cases of puerperal insanity occur without preceding or coincident puerperal infection.

The reasons for this opinion may be briefly summed up as follows:

1. Puerperal insanity occurs in the great majority of cases within the first ten days after delivery—about one-half in the first five days—the same period during which puerperal infection usually occurs.

2. It is usually accompanied by elevation of temperature and other evidences of febrile disturbance.

3. The clinical form in which puerperal insanity man-

ifests itself is, in the majority of cases, that of acute delirious or confusional mania. Depressive states are rare, except as secondary forms. In other words, the most frequent condition is one most closely resembling febrile delirium.

4. The death-rate is much higher than in simple mania. Death occurs from exhaustion, usually with high temperature and rapid pulse.

5. Post-mortem examinations, though infrequent in these cases, have shown grave involvement of the pelvic viscera.

6. Examinations of the pelvic organs during life show lacerations of the perineum and cervix uteri (facile channels of infection in the puerperal woman). As secondary conditions are found intra-pelvic (peritoneal) inflammations and consequent abnormal locations, fixations, and congestions of the uterus, tubes, and ovaries.

7. The results of operations seem to show that removal of local sources of irritation increases the chances of recovery from the mental disease.

DR. D. TOD GILLIAM, of Columbus, O., read a paper entitled "Ventral Hernia Resulting from Abdominal Section." He stated that the safeguards against ventral hernia are the slippery and vaulted parietal peritoneum, which continually shifts the pressure; the fascia; the interwoven commissural fibers; the arrangement of the fibers of three sets of muscles. The factors contributing to the development of ventral hernia are a roughened and sacculated peritoneum concentrating the pressure; scar-tissue, which has not the powers of resistance of normal tissue; and the disturbance of relations of the parietal components.

In long-standing cases, with large and pendulous pouches, the viscera become displaced, the mesentery prolapsed, and the cavity proper contracted. This adds greatly to the difficulties of the operation, because the cavity can no longer accommodate the viscera.

The ideal operation would be to restore a smooth, regular peritoneum and the normal relations of the superimposed structures, to enlarge the cavity and to strengthen the visceral supports. This, as a rule, is impracticable, and the intra-peritoneal operation is fraught with so much danger as not to be practicable.

The operation of cutting down to the fascia on one side of the median line, reflecting it to an equal distance on the opposite side, dissecting up the muscles from the middle line outward in both directions, overlapping and securing them by suture, is full of difficulties, and while offering many advantages over the direct median section, is not likely to come into general use.

The operation of election must be simple, safe, easy of execution, and lasting in its results. A preliminary treatment is necessary to enlarge the cavity, restore the viscera, and strengthen the muscles. This will consist in keeping the patient recumbent, regulating the bowels, massage, the Trendelenburg posture, and the use of remedies to combat flatulence. The utmost care is necessary to secure asepsis, for the efficacy of the operation depends upon the avoidance of suppuration. The operation will consist in an elliptic denudation of an inch or more in width, around the margin of the hernial pouch, and to the depth of the fascia, infolding of the hernial pouch toward the cavity, and a series of layers of buried catgut sutures so as to coaptate the denuded surfaces perfectly. The dressings consist of antiseptic gauze, held in place by strips of adhesive plaster, anchored well down on the sides and tied with tapes over the median line. Over all are placed the cotton pad and flannel bandage.

DR. ANDREW F. CURRIER, of New York, read a paper on "The Causes and Treatment of Sinuses Resulting from Abdominal Section."

He stated that Nature is engaged in a constant effort to protect the body from the results of injury, mechanical or chemic. The ancients recognized this influence in the words *vis medicatrix naturæ*.

Dr. Currier reported the case of a young Irishwoman, who had been operated upon for tuberculous peritonitis, the abdominal wound having been left open for drainage. The parietal surface of the peritoneum remained free, while a wall of new tissue gradually formed over the intestines and omentum, completely isolating them from the parietal peritoneum. The bladder, uterus, and appendages occupied the great sinus thus formed between the layer of new tissue and the abdominal wall. The new tissue was friable, not very vascular, showed little tendency to contract, and was adherent to the parietal peritoneum only at its extreme limits in the flanks. Here, then, was an example on a colossal scale of the sinuses that occur so frequently after abdominal section. Such sinuses may indicate conservative action on the part of the peritoneum. The new tissue, of which they are constituted, is of low organization, but retrogressive changes in it may be incomplete, and result in a persistent opening, with purulent discharges.

The causes of such a condition may be constitutional, irritative, or septic.

Constitutional or predisposing causes are found in cases in which the peritoneum evinces a tendency to throw out excessive secretion. They are present in cases of peritoneal tuberculosis, syphilis, malignant disease of the peritoneum, or disease of any of the abdominal viscera, in which the visceral or peritoneal circulation is seriously interfered with.

Irritative causes may be mechanical or septic, but in the latter variety the irritation may be chemic as well as mechanical. Glass drainage-tubes are chief among irritative agents, especially when very large and retained for too long a time. A sinus thus formed may disappear after the removal of the tube, but it may also remain persistent.

Sinuses may be caused by the irritation of too many or too large ligatures or sutures, or by loosened ligatures around tissues that have shrunk or atrophied. It has been shown that the process may be an aseptic one. To overcome the irritating effects of ligatures, the substitution of the actual cautery, as far as possible, and the removal of the ligatures, securing the pedicle as soon as the danger from hemorrhage is over, have been recommended. Gauze as a means of drainage within the abdominal cavity is probably less irritating than tubes of glass, rubber, bone, or other firm material, and it has been so employed by not a few surgeons.

Sepsis is, as yet, a too obscure cause of sinuses, to admit of exact statement. Sinuses sometimes form when drainage has not been provided for. The ligature may have been aseptic, but blood, pus, serum, or necrotic tissue may act as a focus of irritation; or the peritoneum

may have been unable to absorb or successfully isolate the poisonous material introduced from without. The presence of sinuses may be attended with annoying and often deleterious consequences. The function of the intestines may be interfered with; and there is always the danger to vital organs from prolonged suppuration. Not unusual complications are fistulæ of the bladder and intestine, vesical irritation, nephritis, anemia, and aggravation of preëxisting syphilitic or tuberculous disease. The alternatives in the treatment of sinuses are expectancy, palliative measures, and radical measures. Expectancy is often followed by spontaneous cure. This is the more likely to occur if the nutrition is sustained. Palliative measures are numerous and of varying utility. Thorough cleanliness is a requisite, although often difficult to secure if the sinuses are long and irregular. Various antiseptic solutions, employed as hot as can be comfortably borne, are useful for irrigation. The abdominal opening should be large enough to permit free exit of discharges. Applications of silver nitrate and of trypsin have been made with advantage. The latter will not only digest the cicatricial tissue of the wall of the sinus, but, unless great care is exercised, it will also effect an opening into the intestine or bladder.

In some cases drainage from the abdomen through the vagina has proved efficient, but it has failed in other cases. The removal of an offending pedicle-ligature is not always followed by healing of the sinus.

For obstinate cases, there remains only the radical procedure of re-opening the abdomen, breaking up adhesions, and dissecting away adventitious tissue.

In the discussion, DR. ROHÉ described the difficulties of proper treatment in asylums governed by routine.

DR. EASTMAN and DR. JENKS urged the need of proper consulting boards for asylums.

DR. RICKETTS reported cases of insane women improved by removal of diseased ovaries.

DR. MANTON from extensive observation thought that such patients were improved, but not cured by operation. One case that was under observation for three years was cured. Many such cases are not puerperal in origin.

DR. DAVIS stated that in alcoholic, syphilitic, or neurotic patients, operation often fails. The removal of diseased organs causing irritation in otherwise healthy individuals may succeed.

DR. W. H. WATHEN, of Louisville, read a paper on "The Prevention of Stitch or Mural Abscesses and Ventral Hernia in Laparotomy." He stated that he avoids stitch-abscess by making clean incisions with a sharp knife. He uses no scissors, retractors, or hemostatic forceps. He avoids separating the peritoneum from the wall of the abdomen. He cuts away shreds of tissue in the edges of the incisions. He avoids strangulation by suture. He makes a separate suture for the peritoneum and fascia with kangaroo tendon; then approximates the muscles with silkworm-gut.

In the discussion, DR. JENKS stated that he closes the abdominal incision with one suture, including all the tissues. Traumatism causes most stitch-abscesses and hernias. Dr. Jenks prefers to drain by aseptic gauze.

DR. MCMURTRY maintained that mural abscesses are caused by sepsis. Patients should remain in bed a reasonable time to avoid hernia.

DR. GORDON contended that drainage is rarely needed. He uses a simple suture of silkworm-gut; abscesses rarely result. Sponges constitute septic foci; they should be treated with mercuric chloride before they are used. Needles should be passed from within outward.

DR. EDEBOHLS considers stitch-hole abscess an indication of a septic operation. To avoid ventral hernia he uses chromicized catgut. He unites the deep tissues with buried sutures of silkworm-gut, and sews the superficial fascia and skin with a running, loose catgut suture. He treats ventral hernia by removing an oval flap of skin, folding in the peritoneum, splitting the muscles, and closing the different layers of tissue separately.

DR. WILLIAM E. ASHTON, of Philadelphia, read a paper "On Intestinal Obstruction Following Abdominal and Pelvic Operations," the full text of which is to appear in a subsequent number of THE MEDICAL NEWS.

DR. L. S. MCMURTRY read a paper on "The Influence of Delayed and Incomplete Operations upon Mortality in Pelvic Surgery." He contended that delay in cases of inflammation and in cases of uterine fibroids causes danger, fatal in the case of ruptured tubal pregnancy. Incomplete operations are dangerous because existing disease is aggravated and complicated by the failure to remove the disease. As the knowledge of the dangerous conditions that may be present in the pelvis and abdomen becomes more general and common, family physicians will recognize these conditions early and avoid the danger of delay.

(*To be continued.*)

NEWS ITEMS.

The Medical Society of New Jersey will hold its one hundred and twenty-sixth annual meeting at Atlantic City, N. J., June 28 and 29, 1892.

The President, Dr. Elias J. Marsh, will deliver the annual address, taking for his subject "Longevity."

Dr. J. W. Stickler will read a paper on "Bovine Tuberculosis as Related to Man."

A discussion upon "The True Pathology of Sudden Death in Acute Pneumonia, and the Best Means of Averting it," will be opened by Dr. C. F. J. Lehlbach.

Dr. O. H. Sproul, the third Vice-President, will deliver an address on "Obstetrical Statistics."

Dr. Sidney Strailey will read a paper "The Thymus as Related to Pertussis."

The American Association of Andrology and Syphilology will hold its sixth annual meeting at Richfield Springs, N. Y., June 21 and 22, 1892. The following program has been arranged:

First Day—June 21st.

Discussion on "Prostatectomy," introduced by Dr. William T. Belfield, of Chicago, and participated in by Dr. John P. Bryson, of St. Louis, Dr. William N. Wishard, of Indianapolis, and other members of the Association. In connection with this discussion Dr. Bryson will read a paper entitled "Prostato-myomectomy by the Supra-pubic Route; with a Report of Results Obtained in Eleven Cases." "A New Form of Lithotrite and Aspirator, with Cases Illustrating their Use," by Dr. George Chismore, of San Francisco. "Pelvic Abscess

in the Male," by Dr. William T. Belfield, of Chicago. "The Perfected Electro-urethroscope," by Dr. W. K. Otis, of New York. "A Case of Sacculated Bladder," by Dr. Arthur T. Cabot, of Boston. "Partial Extirpation of the Sound Bladder in the Removal of Neoplasms," by Dr. F. Weir, of New York. "Observations in Regard to the Pathology and Pathological Anatomy of Nodular or Granular Cystitis; Preliminary Paper," by Dr. Samuel Alexander, of New York. "Local Treatment of Cystitis," by Dr. W. K. Otis, of New York. "Retention of Urine; Exhibition of a Catheter for its Relief," by Dr. J. Blake White, of New York.

Second Day—June 22d.

Discussion on "Urethral Fever," introduced by Dr. John P. Bryson, of St. Louis, who who will read a paper in this connection entitled "The Influence of Asepsis and Antisepsis on the Prophylaxis of Urethral as Distinguished from Urinary Fever." Dr. F. Tilden Brown, of New York, will follow with a paper entitled "The Pathology of Urethral Fever." The discussion will be continued by other members of the Association. "The Pigmentary Syphilide," by Dr. Robert W. Taylor, of New York. "The Pathology of Syphilitic Nephritis," by Dr. John A. Fordyce, of New York. "Sexual Hygiene," by Dr. Edward R. Palmer, of Louisville. "Further Report on the Treatment of Gonorrhea," by Dr. W. Frank Glenn, of Nashville. "Practical Points about Recurrent Villous Growth in the Bladder, and its Removal upon Recurrence by the Supra-pubic Route," by Dr. Edward L. Keyes, of New York. "Congenital Deformity of External Female Genitals, Entire Absence of Urethra. Spontaneous Dorsal Dislocation of the Hip as the Result of Efforts to Retain Urine. Correction of Deformity and Restoration of Urethra by Plastic Operation. With some Observations upon the Technique of Ureteral Catheterism," by Dr. Samuel Alexander, of New York. "Unusual Microscopic Bodies Found in the Secretions and Urinary Sediment of a Patient Suffering for Seventeen Years with Urethral Discharge," by Dr. F. Tilden Brown, of New York. "Varicocele and its Radical Cure," by Dr. J. Blake White, of New York. "Failure of Diuretin to Prevent Urethral Fever; a Supplementary Note," by Dr. Edward L. Keyes, of New York. "Operative Treatment for the Relief of Urinary Fistulæ," by Dr. J. Blake White, of New York.

The American Neurological Association will hold its eighteenth annual meeting at the New York Academy of Medicine, June 22, 23, and 24, 1892. The following papers are to be read:

"The Pathology of Paralysis Agitans," by Dr. Charles L. Dana. "Separate Provision for Epileptics, both Public and Private," by Dr. Henry R. Stedman. "A Study of the Sensory and Sensory-motor Disturbances Associated with Insanity from a Biological and Physiological Standpoint," by Dr. H. A. Tomlinson. "Phthisis in its Relation to Insanity and Other Neuroses," by Dr. Thomas J. Mays. "The Successful Management of Inebriety," by Dr. C. H. Hughes. "The Seat of Absinthe Epilepsy," by Dr. Isaac Ott. "On the Extent of the Visual Area of the Cortex in Man, as Deduced from the Study of Laura Bridgman's Brain," by Dr. H. H. Donaldson. "The Criminal Brain; Illustrated by the Brain of a Murderer," by Dr. H. H. Donaldson. "Researches upon the Etiology of Idiopathic Epilepsy," by Dr. C. A. Herter. "Report of Two Cases of Fracture of the Spine in which Operations were Performed for the Relief of Sensory Symptoms," by Dr. Graeme M. Hammond. "Progressive Muscular Atrophy. Presentation of Specimens, with Remarks on the Functions of Certain Cell-groups in the Anterior Horn," by Dr. Graeme M. Hammond. "A Case of Brain Tumor, with Presentation of Specimen," by Dr. Wharton Sinkler. "Report of a Case of Infantile Cerebral Hemiplegia, with Autopsy (Microscopical Preparations by Dr. Warren Coleman)," by Dr. E. D. Fisher. "Report of One Hundred and Sixty Cases of Epilepsy," by Dr. S. G. Webber. "Presentation of a Case of Huntingdon's Chorea; also One of Congenital Huntingdon's Chorea, the First on Record," by Dr. Landon Carter Gray. "A Further Contribution to the Pathology of Arrested Cerebral Development," by Dr. B. Sachs. "A Case of Cerebral Tumor Illustrating the Difficulties of Diagnosis," by Dr. B. Sachs. "Traumatic Nervous Affections," by Dr. Philip Coombs Knapp. "A Note on the Use of Exalgin in Nervous Affections," by Dr. William C. Krauss. "Two Cases of Severe Pressure Neuritis," by Dr. William C. Krauss. "Westphal and his Neurological Work," Dr. W. R. Birdsall. "The Association of Hysterical Trembling and Anorexia Nervosa, with Report of a Case," by Dr. James Hendrie Lloyd. "Sleep Movements of Epilepsy, by Dr. J. W. Putnam. "Diabetes in its Complementary Relations to Certain Forms of Mental Defects," by Dr. E. C. Spitzka. "Imperative Movements Associated with So-called Pseudo-hypertrophic Infantile Palsy, by Dr. E. C. Spitzka. "A New Symptom Indicating Combined Cerebellar and Spinal Incoördination," by Dr. E. C. Spitzka. "The Basis of the Prognosis in the Traumatic Neuroses," by Dr. J. J. Putnam. "Microscopic Specimens Illustrating: 1. The Nerve Alterations in a Case of Beri-beri; 2. The Nerve Alterations in a Case of Scleroderma; 3. The Alterations in Nerves Excised for Neuralgia," by Dr. J. J. Putnam. "Some Contributions to the Study of the Muscular Sense," by Dr. G. J. Preston. "Fissural Studies," by Dr. Burt G. Wilder. "Preliminary Report of the Committee on Neuronymy," "Three Cases of a Hitherto Unclassified Affection Resembling, in its Grosser Aspects, Obesity but Associated with Special Nervous Symptoms. A Tropho-neurosis Possibly Related to Diseases of the Thyroid Gland, not Myxedema," by Dr. F. X. Dercum. "Two Cases of Akromegaly, with Remarks on the Pathology of the Disease," by Dr. F. X. Dercum. "Discription of an Additional Chinese Brain," by Dr. F. X. Dercum. "The Toxic Origin of Insanity," by Dr. Theodore H. Kellogg. "Folie à deux, with Remarks on Similar Types of Insanity," by Dr. Charles K. Mills. "Three Cases of Folie Communiquée," by Dr. James Hendrie Lloyd.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment, provided that the request for reprints be noted by the author at the top of the manuscript. When necessary to elucidate the text, illustrations will be provided without cost to the author.

CONDITIONS INDICATING CHANGE OF AIR AND BATHS IN THE SUMMER DIARRHEA OF CHILDREN.[1]

BY SIMON BARUCH, M.D.,

VISITING PHYSICIAN TO THE NEW YORK JUVENILE ASYLUM, MANHATTAN GENERAL HOSPITAL, AND CONSULTING PHYSICIAN TO THE MONTEFIORE HOME FOR CHRONIC INVALIDS, NEW YORK.

THE removal of the causes of disease being the chief aim of modern therapy, the unsanitary conditions that actively contribute to the development and maintenance of the summer diarrhea of children constitute an important element in the prophylaxis.

Change of Air—does not, as is sometimes erroneously supposed, improve the condition of the sick child by reason of any special difference in the proportions of oxygen or other chemic constituent. The chief factors that warrant us in advising change of air are (1) high temperature and marked humidity, or both; (2) the presence of impurities.

The pronounced influence of high atmospheric temperature and extreme humidity in the causation and maintenance of summer diarrhea in children has long been observed. Whenever, therefore, the usual treatment seems unavailing, especially when extreme prostration, with or without febrile exacerbations, becomes an element in a case of summer diarrhea, the question of change of air becomes important. Of what avail are stimulants, tonics and food, when the little sufferer is forced to toss under the constant, relentless systemic oppression produced by a stifling atmosphere, especially if aggravated by an excess of moisture, from which there is no escape, even by the most careful ventilation. Rich and poor are alike crushed under this terrible combination; for even in the open parks of the city it operates in full force. Removal by a rapid and comfortable journey to high altitudes or seaside, sufficiently remote to furnish a complete change from one or both of these prejudicial atmospheric conditions, becomes imperative in many cases. The change in the entire aspect of a case of summer diarrhea under such favoring conditions has been so often observed that I need not emphasize its importance.

The existence of atmospheric impurities demands removal of the little patient. This is so trite an observation that it would be absurd to dwell upon it, were it not so frequently disregarded. To the credit of the medical profession be it said that its disregard is chiefly chargeable to circumstances over which it has no control.

Among the well-to-do classes atmospheric impurities are rarely operative in summer. While imperfect ventilation frequently breeds such impurities in winter, even in the best-appointed dwellings, the advent of summer forces the occupants to open doors and windows for their comfort and convenience. Unless, therefore, the residence lies in a narrow or overcrowded street, or in one of those elegant but cramped apartments which are really but gilded tenements, change of air will rarely be required in this class of patients.

How different is it among the poor, who are always with us, and to aid and relieve whom is the highest and noblest privilege of civilized man. The noisome tenements in which the children of the poor, and many even of the better class of working-people, are huddled together, are excellent places for the culture and propagation of the elements that contribute to the development and maintenance of summer diarrhea in children. The chief aim in the treatment of the latter is now recognized to be clean food taken into a clean stomach, and its detritus removed as far as possible through a clean intestinal tract. The difficulty of meeting these indications in apartments abounding in dust and emanations from numerous human beings crowded together need but be referred to here. Hence, removal from the influence of this prominent etiologic factor becomes imperative, not for the purpose of securing, as was formerly held, air containing more oxygen, but with a view of having the patient surrounded by air containing less filth and its accompanying bacteria.

How to furnish these poor people with the means of obtaining so important a curative agent as change of air has long been a problem. Fortunately, charitable people have gone earnestly to work to solve it. It is a singular coincidence that just at the moment when these lines were penned, the mail brought me the program of an entertainment to be given for the benefit of one of these charitable enterprises, the St. John's Guild, which has built seaside hospitals, and furnishes thousands of sick children an opportunity to escape for a day or longer from

[1] Read before the Pediatric Section of the New York Academy of Medicine, May 12, 1892.

the depressing influence of impure air, besides giving them good food and medicines. To the poor, whose children require it, this change from a filth-laden atmosphere to the pure breezes of a harbor comes as a refreshing and vivifying blessing that cannot be over-estimated. Such recognition of the value of change of air in the treatment of the summer diarrhea of the children of the poor offers a more convincing argument than aught I can bring forward to establish it.

It behooves us, therefore, to further a charity the object of which is so laudable and practically beneficent.

There is one point in connection with change of air as a remedy that requires special emphasis. While, for reasons already mentioned, a change is imperative in almost all cases of summer diarrhea of the children residing in crowded tenement-houses, it is not so important in those cases whose environment is more favorable for home-treatment. Indeed, the change from a comfortable home to a country hotel, which is apt to be overcrowded, is not to be advised without careful reflection. It is not an infrequent occurrence to order a sick child away when the symptoms become alarming, without time for preparation or due inquiry. The consequences are discomfort from immaturity of plans, great expense, disturbance of the family, and consequent anxiety and unhappiness for the parents and friends.

Do the benefits to accrue to the little patients warrant these? The advantages and disadvantages of removal should be well weighed ere a change of air is decided upon; but, above all things, we must be satisfied that we have exhausted all other treatment. As I have said already, careful attention to sterilization of the food and to intestinal irrigation are of far greater importance than change of air. *We should be sure that these have been fairly tried before advising the change.* This statement is made as the result of practical observations at a noted summer resort, where I see many such cases every summer. To illustrate: In the summer of 1890 I was asked by Dr. Alfred Meyer, who was ill, to see for him a wizen-faced infant whose mother, being poor, had, at great sacrifice, brought it to a third-rate hotel at Long Branch for change of air as a last resort. The child had not improved, simply because its food was not proper and its intestinal canal had not been flushed. One dose of castor oil, followed by two intestinal irrigations and the use of sterilized milk, obtained by converting her medicine bottles and saucepan into a sterilizer, brought about a rapid recovery, enhanced by the constant exposure of the infant to the pure, ozone-laden air. Last summer I was called to the Long Branch home of the Babies' Shelter of New York to see two children whose diarrhea had not improved under the best dietetic and medicinal care in the city and after several weeks' residence in the country. A few intestinal irrigations sufficed to make a complete change in these cases, and contributed more to their recovery than change of air had done. The lesson from such cases is evident. While all cases of summer diarrhea of infants living in crowded houses demand change of air, other treatment is at least equally important. Among the better-situated, change of air need not be insisted upon until all approved methods of treatment have been fairly tried.

Conditions indicating Baths.—In the brief time at my disposal, the discussion of this subject must be cursory. Baths for cleanliness are always demanded in summer diarrhea, not only because the frequent soiling renders them more necessary, but because the maintenance of the functions of the skin seems to relieve internal congestion and fluxion.

In acute cholera infantum, baths for therapeutic purposes are of paramount importance, affording more positive relief and contributing more to the cure than all other measures. This form of summer diarrhea has by some not inaptly been regarded as a type of heat-stroke. Certain it is that if the temperature is taken in the rectum, it will almost always be found high; not infrequently there is hyperpyrexia, though the skin of the extremities and face be cool and clammy. Whenever the temperature exceeds 102° F., a cooling procedure is indicated. It is important that the proper method of bathing should be adopted, and that its *rationale* be well understood.

In these cases there is usually profound involvement of the nervous system, frequently manifested by a dull, apathetic countenance, sunken eyes, deadly pallor, cool extremities, not rarely terminating in outspoken eclamptic seizures. Medicines and stimulants are useless, because the stomach and rectum do not tolerate them. Such a child should be put at full length into a tub of water at 90°, after its face and head have been bathed with ice-water; gentle friction should be constantly made, while someone is removing with a pitcher the tepid water and replacing it by ice-water poured over the side of the tub farthest from the patient's body. The temperature of the bath is thus gradually lowered to 80°. If there be marked cerebral disturbance, water at 60° may be poured upon the head and shoulders. The child's body must be entirely submerged, the head only not being immersed. Its cries and protestations of chilliness must be met with gentleness, yet with firmness. For fifteen minutes the agitation of the water and friction of the body should be kept up, unless cyanosis of the face or decided shivering ensues. The latter will

be prevented by active friction, which stimulates the peripheral circulation.

After the bath the child is placed upon a linen sheet, previously laid smoothly upon a blanket. If the temperature before the bath — and it should always be taken at this time—has been 103.5° or higher, the child should be wrapped in the sheet so that every part of the body and extremities is well covered by it; the blanket is now snugly wrapped over and tucked under the body, which is thus allowed to dry. If, on the contrary, the temperature has been below 103.5°, the child should be gently mopped dry and its clothing be replaced at once. Such a bath is almost invariably followed by calm and refreshing slumber, from which the child awakens bright and playful.

Let it be understood that the object of this bath is not to reduce temperature, although this is an important incidental result. We have here a vasomotor paralysis, as evidenced by the pallor of the entire body, even when a high temperature is registered in the rectum. By immersing the entire body in tepid water we produce a mild shock, which is gradually increased by the removal of warm and the addition of cold water, and is enhanced by frictions of the body and constant agitation of the cooling water against the skin. These gentle shocks are succeeded by equally gentle reactions, so that the cutaneous vessels dilate, as evidenced by redness of the skin. If, in addition, the face and head are bathed with a little colder water, at 60°, the shock and reaction are increased, the respiration deepens, the heart beats with more vigor and less rapidity, the eye brightens, the color returns to the lips, the child becomes more animated.

The effect of a skilfully-administered bath in the condition of nerve-prostration incident, in many children, to acute summer diarrhea must be observed to be fully appreciated. In my experience it has been an inestimable boon, affording hope and comfort under the most trying and desperate conditions. My mind still retains vivid recollections of the days when I was a student and of the early years of my practice, when the condition of profound adynamia, usually associated with hyperpyrexia, was called spurious hydrocephalus, and the cases were allowed to die under blisters to the nucha and small doses of calomel. These cases do not now come under my observation; they are forestalled by the bath and by more rational treatment, foremost in which is judicious gastro-intestinal irrigation.

When there is objection or prejudice to tub-bathing, or when there is extreme jactitation, or when there are convulsions, the little patient may be placed in the wet pack, or the bath may be followed by the latter to maintain the calming effect. The wet pack is prepared by wringing out of water at a temperature of from 50° to 60° a linen sheet folded into a third of its usual size and smoothly laid (folded to suit the size of the child) upon a blanket. The child is snugly wrapped in the damp sheet (which may be made more wet if the temperature be high), so that the arms receive a fold to separate them from the body, and the legs a fold to separate them from each other. The blanket is now snugly tucked around the child, so as to completely envelop it, like a mummy, to prevent evaporation. This pack may be repeated two or three times, at intervals of ten minutes. The previously tossing child will usually drop into tranquil slumber, from which it should not be aroused. After the wet pack the body should always be rubbed with a linen cloth not quite wrung out of water at 70° F., and dried.

In the subacute form of summer diarrhea the chief condition indicating baths is the general depression of the system arising from the great drain upon the blood and nervous system. The pulse is usually rapid; the temperature ranges from 99° to 101°, with occasional exacerbations; the skin is inelastic; the face is sallow; in short, the symptoms are those of chronic adynamia, due to imperfect nutrition. To stimulate the appetite, improve the general nervous condition—in a word, to refresh the entire organism—should be our therapeutic endeavor. The most approved tonics and stimulants often fail, as Dr. Chapin has so graphically and poetically told us. In these cases general ablutions, morning and evening, are preferable to baths. The child is placed upon a soft woolen blanket; the abdomen, chest, and back are rapidly bathed, not sponged, as follows: From the hollow of the naked hand water at a temperature of 75° F. is poured upon the skin, which is then gently rubbed with the same hand. This is repeated until the entire body has been thus treated as far as the knees and elbows. The body is now rapidly dried by placing it upon a linen sheet, using friction with a rough towel if the temperature is below 99.5°, and only gentle mopping if it is above 100° F. If the temperature reaches 102°, a general bath is indicated, beginning with water at a temperature of 95°, which is gradually reduced by agitation and friction to 85°. Gentle drying follows.

The refreshing effect of these procedures has been so frequently observed that I do not hesitate to commend them to your adoption. There are many modifications of baths indicated by the various symptoms in summer diarrhea of infants. The time-limit precludes their description. Suffice it to say that no case should be regarded as intractable or too desperate until some form of hydriatric procedure (the adaptation of which to each case often requires more judgment than that of medicinal agents) has been tried.

SIMPLE FRACTURE OF THE SHAFT OF THE FEMUR, AND ITS TREATMENT WITH THE LONG SPLINT.[1]

BY N. F. GRAHAM, M.D.,
PROFESSOR OF SURGERY, MEDICAL DEPARTMENT, HOWARD UNIVERSITY, WASHINGTON, D. C.

A VERY special interest attaches to fractures of the femur, for the reasons—First, of the desirability that firm union, with the least possible degree of deformity, either angular, rotatory, or from shortening, shall result; and, secondly, that this result shall be obtained with the minimum degree of discomfort to the patient during the treatment.

The use of the lower extremities is primarily to sustain the weight of the body and for locomotion. In addition to this, the femur and the bones of the leg are often called upon to sustain great additional weights, proportioned to the strength of the individual and the requirements of his occupation, often amounting to hundreds of pounds, so that, when fractures take place, the end and aim of the treatment should be to restore the limb unimpaired in shape, strength, and action.

Experience and observation have shown that a little over 50 per cent. of fractures of the femur occur in the middle third, about 30 per cent. in the lower third, and a little less than 20 per cent. in the upper third. I desire to confine myself in this article to the consideration only of fractures occurring in the middle third, in the upper half of the lower third, and in the lower half of the upper third; or, in other words, those occurring at a distance from the hip-joint and knee-joint. The majority of fractures, occurring anywhere in the length of the bone, are due to indirect violence. Confining ourselves to the parts of the shaft that I have selected, we find that direct violence is the most important factor.

When there is entire division of the shaft of a long bone, the two fragments are, as a rule, displaced as regards their relation with each other in one or more ways. First: Transversely, varying from a small part of the diameter of the bone to its entire width or even more. Second: Longitudinally, as when the fragments override one another, causing shortening. Third: Angularly, as when the ends of the fragments remain in contact, but by the contraction of the muscles the limb is shortened, causing the long axis of the limb to form an angle. With any of these may be combined rotation of one of the fragments on its long axis.

I am not aware that such a thing as a purely lateral displacement ever occurs; but, in the event of its occurrence, we should not expect shortening, while with longitudinal or angular displacement there is always shortening.

Extension, counter-extension, and coaptation will remedy the transverse, longitudinal, and angular defects, whilst the rotatory displacement is corrected by rotating the lower fragment until its position corresponds with the upper one. By these means, combined with retentive dressings, immobility of the fragments is permanently secured until bony union is complete. This varies as to time according to the age and condition of the subject. Lameness and soreness at the seat of the break and in the knee persist for a number of weeks, and sometimes for months after all artificial support is discarded.

The very general rule is that, after most careful adjustment of the broken bone, and with most skilful management afterward, there will be some degree of shortening, varying from one-fourth of an inch to an inch, the mean being about one-half of an inch.

Up to a certain limit, measurements cannot be relied on, as there are reasons that make them inexact. To say that a leg is one-eighth, or even one-quarter, of an inch shortened by a fracture places the correctness of the measurement under suspicion. Besides, the points between which the measurements are made vary as to position and conformation. The malleolus on one side may be longer or shorter than its fellow, or the anterior superior spinous process of the ilium may be situated lower or higher than its opposite.

Permanent lameness may result from the smallest degree of shortening, owing to the inability of the individual to drop the pelvis toward the shortened side so as to compensate for the difference in length of the limbs. On the other hand, others adapt themselves in a short time to the changed conditions, so that no lameness exists even when the actual shortening amounts to an inch. I do not believe that a limp can be prevented when one limb is more than one inch shorter than the other, whether the shortening be congenital, or due to a break.

After fracture of the femur, the chances for good results, so far as length is concerned, are governed in some degree by the limb that is fractured. A larger percentage of left femurs are known to be longer than the right, in cases in which a difference exists. The most reliable statistics show that in only 10 per cent. of all cases are the femurs of equal length. In the 90 per cent. in which inequalities exist, the right femur is longer in 35.7 per cent. and the left in 54.3 per cent., so that in a larger number of fractures of the left femur the shortening following a fracture is not apparent on measurement after repair has taken place. This accounts for the clinical fact, long observed, that fewer left femurs were

[1] Read before the Medical Society of the District of Columbia, at its meeting on March 23, 1892.

shorter than the right after recovery from fracture, the explanation of which is found in the more recently acquired knowledge of the natural difference in length and the relation it bears to the two sides.

It may be that great shortening is found after a fracture, a small part only of which is due to the treatment. The natural difference in the length of the thigh-bones may be as much as an inch. Let us suppose that in such a case a fracture occurs in the shorter femur and unites with half an inch of shortening, due to the fracture. This, added to the inch of natural deformity, would give a total shortening of one and one-half inches, enough to cause a decided limp, yet the main part of it would be due to the natural defect.

Conversely, a femur an inch longer than its fellow might be fractured and shortening of an inch or more result, with the effect of restoring uniformity of length without lameness, provided that the proper relation of the axes of the two fragments were maintained; that is to say, if there were no angular or rotatory deformity. When there has been an oblique fracture of the shaft of the femur, and when, after repair, no shortening can be made out, it may be accepted that the bone that was broken was longer than its mate.

To get union after fracture of the femur, without leaving a trace of the injury in shape or usefulness, has engaged the attention and taxed the ingenuity of eminent surgeons, and many complicated appliances have been used, none of which can be said to be entirely satisfactory. Good results have been and can be obtained by any form of apparatus when the management is in the hands of expert surgeons. It must be remembered, however, that a large proportion of the fractures are not treated by surgeons of experience, but by men who see and treat but a limited number in the whole of a long professional career. Only frequent opportunities and the intelligent use of such apparatus can confer expertness.

Many facts in regard to the results after fractures of the femur have accumulated during the past twenty years in my experience, observed almost daily in examining men who suffered such fractures during the late Civil War, and since that time in the regular army and in civil life. These facts have convinced me of the necessity of more reliable and simpler methods than those generally adopted, or of better instruction. My notes show but a small percentage of what could be regarded as good results. About 70 per cent. of the number were treated with the pulley and weight, with elevation of the foot of the bed, and varied retentive appliances: sand-bags, short side and coaptation splints, etc.; the remaining 30 per cent. were treated with the long straight splint, with the perineal band and foot extension. No very gross deformity was met with in any of the cases treated by the latter method, while a number of actual cripples presented themselves, who had been treated by the former plan.

The physician who sees and treats but an occasional fracture should use an uncomplicated and, above all, a safe apparatus. Of these there is none so available and reliable as the long, straight outside splint, reaching from the axilla to a point six or eight inches beyond the bottom of the foot, with its opposite reaching from the perineum to a length beyond the foot corresponding to the long one. This is nothing more than the old Desault splint as modified and lengthened by Physick. The principle of the application of extension and counter-extension is the same as that used by Liston, but the splint applied to the inside of the thigh adds greatly to the certainty with which the fragments can be kept in place.

Only 29.12 per cent. of the population of this country live in cities and towns of four thousand inhabitants and upward, whilst 70.88 per cent. live in the rural districts. The larger proportion of this latter class are engaged in pursuits that expose them to great risks—such as farming, mining, lumbering, railroad construction, quarrying, etc.—and it is but reasonable to expect a large number of fractures among them.

The country practitioner, when called upon to treat a case of fracture, has many difficulties to contend with, and it is not reasonable to expect that he can get so many good results, with the use of similar complicated appliances, as his city brother. The latter has his patient near at hand, and very often in the care of an intelligent trained nurse, whilst the country surgeon has to depend for nursing on the family or friends and has to travel a long distance to visit his case. Frequently he is unable to see the patient often enough to correct faults that may arise at any time when a complicated apparatus is used. The simplicity of the long splints, and the certainty with which they can be kept in place, commend them particularly to the country surgeon; even in cities better results, with less trouble both to the surgeon and the family, may be obtained with them than with any other form of apparatus. Besides, in my experience, the comfort of the patient is very greatly promoted by this splint; for, when properly applied, the movements of the patient up and down in bed do not disturb the fragments. Absolute restraint for any length of time is extremely irksome, and when this is combined with the distressing tension to which a weight hung to his leg subjects the patient, together with the weariness and discomfort resulting from the constant strain on the muscles of the leg and thigh, the result must be well-nigh intolerable.

It requires great skill and much experience to

decide the exact weight to be used. Too great a strain may separate the fragments and prevent union; too small an amount will allow the muscles to contract, causing shortening. All these considerations are eliminated, or, at least, much modified by the use of the long splint. The extension and counter-extension are so applied, at the time of adjusting the fracture, as to bring the muscles to their natural length, as they should be when the limb is extended from hip to ankle, and in that position they are held. The dressing cannot be painful, so far as the muscles are concerned, for they are neither in a state of contraction nor extended beyond the natural, and, above all, they are relieved of the constant drag that becomes so burdensome to the patient when a weight is used.

I do not deny that the pulley and weight may be, on rare occasions, necessary. When the patient is large, strong, and muscular, and when it is difficult to secure the proper length of the limb by immediate extension, the plan of applying a heavy weight, proportionate to the resistance, for a sufficient time to tire the muscles, may be necessary, after which the long splint, with the perineal band and fixation of the foot to the lower extremity may be adopted. In adults, at about the fifth week, the splints may with safety be replaced by a well-applied plaster-of-Paris dressing, reaching from below the knee to the groin. This change of splints is a great relief to the patient, giving more freedom at once, which, however, should be indulged in with care for the following two weeks, after which time he may get out of bed and move about on crutches for a few days, when the cast may be removed. The use of crutches should be continued for a few days, say a week, longer, at the end of which time the femur should be strong enough to support the weight of the body, but no heavy burdens should be carried or heavy lifting be done for a number of weeks more.

It has been urged that it is difficult to apply the long straight splints without the risk of displacing the fragments after adjustment—an objection that is not tenable, provided that the arrangements for their application are properly made and carried into effect.

The first requisite for the treatment of fracture of the femur, no difference what appliances may be used, is a firm, smooth mattress, laid on an unyielding foundation, on which the patient should be placed before the fracture is set. Now the splints should be prepared of suitable length, width, and strength; the outer long enough to reach from just below the axilla to six or eight inches beyond the sole of the foot, as wide as the thickest part of the normal thigh, notched at the lower extremity, and with two holes bored and bevelled at the upper extremity. The inner splint should be of the same width and strength as the outer, and should extend from the perineum to the same distance beyond the foot as its fellow, without holes above or notches below. Both splints must be carefully padded with long, smooth strips of fine absorbent cotton, or a good quality of cotton batting, wide enough to extend a trifle beyond the edges of the splints and shaped to fit the natural inequalities in surface of the limb, the prominences being especially protected. The aim should be to secure a uniform pressure on every part of the length of the limb. The padding can be held in place by strips of muslin long enough to encircle the splint and padding, placed from four to six inches apart, and tied on the outside of the splint.

The perineal band should now be fitted and left loosely in place. A large, soft napkin or handkerchief, carefully folded and—if at hand—covered with oiled silk, answers the purpose well. Next, a strip of strong adhesive plaster, two inches wide, is applied, extending from above the knee, down the leg on one side, around the bottom of the foot, leaving a short loop at the turn, and up the other side of the leg to a point as high as that of beginning. The malleoli should be protected by layers of cotton between them and the plaster. A few short transverse strips of plaster may be applied to give the long strip firmness enough to bear the traction to which it will be subjected.

Then a number of canvas straps with buckles, or, what will answer the purpose just as well, strips of strong muslin a couple of inches wide and long enough to encircle the limb and splints, are laid under the leg and thigh from the ankle to the perineum at intervals of four inches. To complete the arrangement a broad band should be placed under the body, wide enough to extend from the axilla to the hips and long enough to go around the body and lap three or four inches.

Now, with properly applied extension and counter-extension, the thigh is brought to its normal length, and by manipulation the fragments are made to assume their proper relation to each other, an anesthetic being used, if necessary.

The outer splint should now be placed alongside the limb and the free extremities of the perineal band carried through the holes at the top of the splint and fastened. Next, by means of a cord or a strong strip of muslin passed through the loop of adhesive plaster, the foot is securely fastened to the bottom of the splint, and it can be so securely fastened and held between the extending and counter-extending forces as to prevent shortening. The inner splint is now put in place and the straps buckled, or the strips, if they be used, securely tied. If this arrangement be effectively carried out, there need not be the least movement of the limb. The binder about

the body may now be fastened by two rows of safety-pins, one at the exposed and one at the concealed extremity.

There is a safety in this method that no other plan of treatment possesses, and it has the advantage of being easily carried out. If I may judge from the testimony of the patients treated by me by various methods, those treated with the long splint suffered less than those treated by any other appliance. It is found, by observation and a perusal of the statistics of all the larger hospitals in this country and Europe, that about 12 per cent. (the extremes ranging from 7 per cent. to 18 per cent., depending on localities) of all fractures are in the femur. Considering the importance of the bone, it is a matter of no small moment that the management of its fractures should be conducted with effectiveness and simplicity. At the same time the comfort of the patient should not be disregarded.

Of 668 cases of fracture, taken from the records of the Freedmen's Hospital in this city, 84 were of the shaft of the femur, all of which were treated with the long straight splints, with perineal band and foot extension. The results have been all that could be desired. The average shortening, in cases in which shortening was found, did not exceed one-half inch, and there were no instances of angular or rotatory deformity. The average time the splints were left on, during the earlier years of the existence of the hospital, was about six weeks. During the past six years they have been replaced by the plaster-of-Paris dressing at the end of four or five weeks, and the treatment by this method is complete in from six to eight weeks, after which time the patient is allowed to move about freely on crutches for a few days longer.

My own personal experience in the treatment of this fracture covers all the methods recommended, but I have finally settled on the long straight splints as furnishing the most available as well as the most certain plan for securing satisfactory results. With care, the risk of the extending and counter-extending forces becoming relaxed, so as to allow the muscles to contract and cause shortening, is small, and one that has given me but little concern. I have notes of thirty-seven cases treated by me by this method within the last six years. In not one was the shortening enough to cause a limp, and the contour of the limb was normal in every instance.

In conclusion, let me sum up by saying that this plan of retentive dressings for fracture of the femur is easily applied; the splints are easily made, and the patient is more easily and more safely handled than by any other appliance. There is no risk of displacing the fragments if the patient moves up and down, and he may even move sideways to a limited extent — a small liberty that adds greatly to the comfort of the sufferer.

In the case of young children they can be lifted from the bed without risk—an advantage not associated with any other retentive dressing, except the plaster-of-Paris.

It is my opinion, however, that this latter dressing should never be applied during the early days of a fracture, not only of the femur, but of any of the long bones.

A FEW SUGGESTIONS ON THE DIAGNOSIS AND TREATMENT OF LUPUS.[1]

BY WM. THOMAS CORLETT, M.D., L.R.C.P. LOND.,
PROFESSOR OF DERMATOLOGY IN THE WESTERN RESERVE UNIVERSITY; CONSULTING PHYSICIAN FOR DISEASES OF THE SKIN TO THE CHARITY HOSPITAL, THE CITY HOSPITAL, ST. ALEXIS HOSPITAL, ETC., CLEVELAND, OHIO.

IT is not the object of this paper to discuss *in extenso* the various aspects of lupus, nor to detail the several modes of treatment in vogue, but to present in a concise way the main points as to diagnosis and treatment that have presented themselves to the writer from time to time.

It is accepted as a fact that lupus is a local tuberculosis, in main identical in histologic structure with tuberculosis of the internal or more vital organs, and like it due to the bacillus tuberculosis.

The simplest form is called lupus erythematosus. Histologically it is a small-celled new-growth of the skin, best marked about the bloodvessels, clinically appearing in the form of one or more circumscribed, variously sized, reddish patches, covered with grayish-yellow, adherent scales.

Its favorite seat is on the face; it is a disease of middle life, is never seen in childhood or in old age, and is far more common in women than in men. Jonathan Hutchinson states that it is frequently found in persons having a languid circulation, as evidenced by cold hands and feet, and with a purple, mottled skin. Thus, in its incipiency, it seems allied to erythema, which at first it closely resembles. Lupus erythematosus, however, is circumscribed, with well-defined margins, and although at first it may show a tendency to evanescence, yet it always recurs in the positions previously invaded; while erythema is not sharply defined, it extends over a larger area, is markedly evanescent, and tends to invade new surfaces rather than to return to positions previously occupied. As lupus erythematosus develops, its appearance is quite unlike that of erythema, and little difficulty will be experienced in a differential diagnosis.

From rosacea, lupus erythematosus may be distinguished by the engorged condition of the blood-

[1] Abstract of a paper read before the Surgical Section of the American Medical Association, held at Detroit, from June 7 to 10, 1892.

vessels, which in the former constitutes one of the most prominent features. Then, acute inflammation of the sebaceous follicles accompanies rosacea; its distribution is on the tip of the nose, chin, and not infrequently over the entire face, while lupus erythematosus usually appears over the malar bones and extends thence across the bridge of the nose—butterfly-shaped.

Lupus erythematosus may, however, occur on other parts of the face, more rarely on the trunk and extremities, when a diagnosis is oftentimes extremely difficult. In these positions it resembles tinea circinata, but in the latter there is usually a history of contagion; if this be wanting, the only trustworthy means of differentiation at our command is the microscope. After macerating the scales of tinea in liquor potassæ for a few minutes, a sixth-of-an-inch objective will enable one to detect the tricophyton, which is absent in scrapings from a lupus surface.

Eczema in middle or advanced life may resemble lupus erythematosus. This especially applies to the form of eczema found in gouty or rheumatic subjects,[1] which occurs most frequently on the back of the hands, and when one hand alone is involved the resemblance may be quite misleading. In eczema there is invariably a history of moisture in the early stage of the disease—the so-called catarrhal inflammation—and it is usual even late in its course to find groups of vesicles in the neighborhood, notably on the fingers and toes; while the eruption of lupus erythematosus is essentially dry.

Then again, eczema is ill-defined at the margins and gradually merges into the healthy skin, which contrasts with the exaggerated peripheral disturbance that gives to lupus a sharp line of demarcation.

The sensation of itching is of little diagnostic value.

Although the surface of a patch of lupus may resemble that of other affections, yet the bed underlying the scaly covering is peculiar to this disease. On picking up the scales, which are firmly adherent, it will be seen that there are processes extending downward into the sebaceous follicles, which after removal leave the patulous openings of the follicles plainly visible. At other places, blood will be seen oozing from the ragged surface. In eczema, upon removing the scales, the surface will be found moist, as if bathed in copious perspiration.

Psoriasis in a mild form, especially when it occurs in gouty or rheumatic persons, as Liveing has pointed out,[2] at times closely resembles lupus erythematosus; this is notably so when the disease appears on the scalp; but, first, the history of invasion is widely dissimilar in the two affections, psoriasis making its appearance about the age of puberty, while lupus erythematosus appears at a period ranging between twenty-five and forty-five years of age.

Again, the scales of psoriasis are silvery white, imbricated, and less firmly adherent; the base of the patch is smooth or undulating, at times showing the summits of the enlarged papillæ; while the scales of lupus and its base present the features already described.

The extension of the lupoid process downward into the sebaceous sac and hair-follicle interferes with the nutrition of the hair, so that when the disease occurs on the scalp or bearded part of the face in men, the roots of the hairs are destroyed, leaving bald plaques; while in psoriasis the root of the hair is but little, if at all, affected.

Syphilis in its protean manifestations may resemble lupus erythematosus. In the absence of a syphilitic history, which requires the greatest care lest it prove misleading, the lesions themselves may be differentiated; and in this it is well to bear in mind that the lesions of syphilis are more general in their distribution; they are, as a rule, more evanescent and of a darker color. Finally, in case of doubt, a fortnight's treatment with anti-syphilitic remedies may be resorted to. Lupus erythematosus leaves scars that may be scarcely perceptible; in severe cases they resemble parchment.

Lupus vulgaris is a more severe form of the disease. It also is a cellular new-growth, characterized by variously sized and shaped, reddish or brownish patches, which consist of papules, tubercles, or flat infiltrations, usually terminating in ulceration and the formation of disfiguring cicatrices.

This form is more pronounced and consequently less liable to be confounded with other affections. There is one disease, however, in which a positive diagnosis is often extremely difficult, viz., syphilis. This similarity only applies to the late manifestations of syphilis, when the variously-appearing lesions are primarily made up of granulation-tissue. Histologically, lupus likewise comes under the head of granulation-tissue, so that the external aspects of the two affections in the different stages of development and degeneration are closely alike. Generally the histories of the individual lesions—not of the disease, for in syphilis this is frequently misleading—will enable one to determine to which of these affections the case belongs. In lupus vulgaris the lesion will be found first making its appearance early in life, at about the age of puberty, and the eruption is extremely chronic, often remaining for years with but slight variation. The late manifestations of acquired syphilis occur later in life, are more widely distributed, and, although slow in

[1] "Diseases of the Skin in the Subjects of Gout," Journ. Cutaneous and Venereal Diseases, September, 1886.

[2] A Handbook on the Diagnosis of Skin Diseases, London, 1878.

course, their duration is a matter of months rather than of years, as is the case with lupus.

There are also distinctive features in the lesions that the experienced eye may readily detect, but that can be but imperfectly described. The following may be mentioned as the most noteworthy: The base of the lupus patch shows an exuberant growth of granulations, its margins are undermined, and islets of lupus-tubercles are seen in the adjacent skin. In syphilis, the margins are clearly cut, as if punched out, with a smooth, ashen-gray base. Lupus attacks the soft parts, which it destroys; in severe cases cartilage offers no certain barrier to its ravages; but it never attacks bone; not so with syphilis, which late in its course has even a predilection for the osseous system. Again, when syphilis occurs on the face, it is most commonly seen on the upper part of the forehead, the fissures between the alæ of the nose and the upper lip and the angles of the mouth, in which latter positions it is pathognomonic; whereas lupus vulgaris selects in preference the nose, cheeks, and ears. Too much stress must not be laid on the color, for it may or may not be distinctive.

Even greater difficulty will be experienced when lupus invades the trunk or extremities. Here the main point of diagnostic value is the limited area of the eruption, and if accompanied by lupus on other parts, as on the face, its extreme persistency will enable one to exclude the multiple and more short-lived eruptions of syphilis; nor will the microscope aid materially in the diagnosis, as the tubercle-bacillus is difficult to detect and is not found in all specimens examined. As in lupus erythematosus, when doubt still exists a fortnight's treatment with some form of iodine will usually settle the diagnosis so far as relates to syphilis.

It is very seldom that epithelioma or rodent ulcer is mistaken for lupus, yet a limited patch of the latter may bear some similarity to the former; and as epithelioma leads to a fatal termination, and is only successfully treated before the lymphatic glands are implicated, its early recognition is all-important.

First, as to age; lupus appears before thirty-five, while epithelioma comes later in life. The nodules of lupus are multiple, while epithelioma presents but a single lesion. At times, the fungoid growth of the lupus-tubercle contrasts strongly with the ulcer-like lesion of epithelioma. In lupus, the lesion is soft, while in carcinoma the base and margins are hard, and the surface is glazed with a watery secretion.

Occasionally, epithelioma develops on a surface already occupied by lupus. The one case that has come under my observation at St. Alexis Hospital rapidly passed on to a fatal termination.

Lupus verrucosus is a more rare form, and in my experience has been encountered in very strumous subjects early in life. The warty outgrowth is quite characteristic, and once seen cannot well be mistaken for anything else.

The treatment of lupus must also be considered *seriatim*. First, in regard to lupus erythematosus: As in granulomata, scrofulomata, etc., of different writers, the general condition of the patient should be seen to, and at its onset the disease may yield to this alone.

The diet should contain a large quantity of the hydrocarbons, and the form that is most generally acceptable is butter. Following in the same line, cod-liver oil stands in high esteem. Then in the rôle of medicaments come iodine and creasote. Some years ago, Dr. Liveing, of London, carried out what he called the iodine-treatment for lupus. Iodine in various combinations was given internally to toleration, and an ointment of mercuric iodide was applied to the lupus surface. There could be no doubt that cases of lupus at the Middlesex Hospital were greatly benefited, but according to my subsequent experience the disease is not eradicated even after a prolonged course, and it readily resumes its wonted severity on discontinuing the treatment.

More recently Bulkley has extolled the internal use of phosphorus, but my own limited experience with it has not encouraged its further use. At the Hurlbut and Huntington Dispensaries of Western Reserve University, creasote is extensively used by my confrères for tuberculosis,[1] and its employment in the treatment of lupus during the past two years leads me to believe that the remedy is of decided benefit in this disease. The dose varies somewhat according to individual peculiarities, but it is well to begin with from one to two minims in capsule every two hours. This may be increased to three minims every two or three hours.

In severe or neglected cases, however, it will be necessary in addition to attack the disease *in situ*. The following is a simple and efficient procedure: The surface is prepared by washing it vigorously with hot water and the German green soap; the latter is then thoroughly rubbed into the skin and allowed to remain for an hour. The surface is again cleansed, when the scales and follicular processes into the sebaceous glands will be cleared away, leaving a raw surface. Then apply—

℞.—Sulph. precip. . . . . ℥iij.
Glycerini } āā . . . . ℥j.—M.
Alcoholis }

S.—Apply three times a day.

Two or three times a week for a fortnight the green soap should be repeated.

[1] "How to Give Creasote," by Howard S. Straight, M.D., Cleveland Med. Gazette, December, 1891.

In more severe cases I have added to the preceding formula ammonium sulpho-ichthyolate in the strength of 5 per cent., and have found it a valuable adjuvant. Mercury, in the form of the diachylon plaster, the white precipitate ointment, or the oleate (20 per cent.), likewise has its advocates, and is without doubt a valuable application.

In many cases, however, more radical measures are required, and I have found linear scarification, as practised so extensively at the Hôpital St.-Louis by Vidal, the most efficient means at our command. The cuts are made entirely through the derma and closely together, then crosswise. After the bleeding has ceased, emplastrum vigo cum mercurio is applied. This dressing should be removed daily, and the scarification repeated twice a week.

In the treatment of lupus vulgaris, what has been said in regard to the hygienic management and internal medication of lupus erythematosus applies with equal force; but more especially in this disease are external procedures required. Bearing in mind that we have to deal with a local tuberculosis that extends indefinitely, constantly invading new tissue, each additional tubercle acting as a new focus of infection, the object of treatment is obviously to cut short this process of extension and to remove the noxious material already formed. This is done as follows: The patient is chloroformed, and with a Volkmann's spoon the tubercles are cleanly scraped out; then the parts are washed with a mercuric chloride solution (1 : 1000), and pyrogallic acid is packed into the excavations thus formed. This dressing is repeated daily for several days; then some simple dressing, such as the white precipitate ointment or the emplastrum vigo cum mercurio, is applied until resolution takes place. Occasionally the pain, subsequent inflammation, and constitutional disturbance are too severe, when some of the milder escharotics should be employed. Of these, creasote and carbolic acid are the best, causing but slight pain and no constitutional ill-effects. Seldom will one operation suffice, for in a few weeks or months brownish spots will be seen; these soon develop into tubercles, when the procedure must be repeated until the cure is complete.

THE DIFFERENT FORMS OF CARDIAC PAIN.[1]

By SAMUEL C. CHEW, M.D.,

PROFESSOR OF PRINCIPLES AND PRACTICE OF MEDICINE IN THE UNIVERSITY OF MARYLAND, BALTIMORE.

Cardiac pain is a symptom belonging to several affections that differ from each other in their nature and pathology. These maladies have all the common property of pain, varying in degree and seated apparently or really in the heart. There is, however, no satisfactory term in English usage for designating this pain. On the ground of analogy, it would seem proper to call it cardialgia, after the examples of gastralgia, cephalalgia, etc.; but this word is already appropriated, illogically though it may be, to an affection with which the heart is not concerned at all. Thus, in the *National Medical Dictionary* of Dr. Billings, the first definitions of cardialgia are gastrodynia and heartburn, the last being pain in the heart. In the *Century Dictionary* and in that of Dr. Foster no other meanings for cardialgia are given than heartburn and gastralgia. Dr. Flint says that "cardialgia signifies pain at the cardiac orifice of the stomach, of a burning character";[1] and Dr. Wm. H. Welch, in his very valuable monograph on *Ulcer of the Stomach*, says: "With most English and American writers cardialgia signifies heartburn, while Continental writers understand by it the severe paroxysms of epigastric pain which we more frequently call gastralgia."[2] This usage, though fixed, is certainly contrary to etymology and to the analogy of similar words. *Heart-pain* would suggest its meaning very plainly, but it is not in accordance with English usage; for we do not say head-pain or back-pain; and if headache, backache, and earache suggest *heart-ache*, we are debarred from that word by the fact that since it was included with "the thousand natural shocks that flesh is heir to" it has always been used to denote emotional rather than physical distress. We are therefore driven to the use of the terms "cardiac pain" or "pain in the heart."

This kind of pain is found as a prominent symptom principally in three different forms of disease of the heart; and I desire to refer briefly to these from a clinical rather than from a pathologic point of view.

The first of these, and the one in which the pain exists in most intense degree, is angina pectoris, true angina with increased arterial tension, occurring in paroxysms, and most frequently associated with aortic or coronary disease or with fatty degeneration of the heart. As the name of this affection implies, the pain is of the very essence of the disease itself. In severe cases it is nothing less than a mortal agony—an agony from the very intensity of the pain, and a mortal agony because, as testified by many sufferers, the pain is attended with a sense of impending dissolution. Nothing can better describe a paroxysm of angina than words used by a non-medical writer, and without reference to this disease, in which he speaks of "a sense of ruin which is worse than pain." As recorded by Dr.

[1] Read at the meeting of the Association of American Physicians, held in Washington, D. C., May 24, 25, and 26, 1892.

[1] Practice, p. 443.

[2] Pepper's System of Med., vol. ii, p. 489.

Latham from his own observations, it is "a suffering as sharp as anything that can be conceived in the nature of pain, including something which is beyond the nature of pain—a sense of dying." Keeping in mind this element of the paroxysms, I think Professor Flint's criticism, that "Heberden's term signifying *strangulation* has but little pertinency in this application of it," is, with all deference to his high authority, hardly justifiable; for Heberden speaks of "the sense of strangling and anxiety with which the disorder is attended"—*angor pectoris intentans vitæ extinctionem*; and he seems to use the word angina with reference to these rather than to the pain alone; to the combination of anxiety and anguish found in the disease; words indeed that come from the same root as angina and bear witness to the accuracy of the term as Heberden first employed it.

The structural changes connected with true angina are in a very large proportion of cases those that produce cardiac ischemia, especially insufficiency or atheromatous rigidity of the aorta, obstruction of the coronaries, or fatty degeneration of the heart. Any one of these changes may lessen the blood-supply to the heart-muscle; but only the first two, aortic insufficiency and obstruction, are diagnosticable with certainty by auscultation; we may suspect coronary obstruction or fatty degeneration, but we cannot during life prove their existence. Hence the prognosis of a case of true angina pectoris may be equally as grave when auscultatory examination yields a negative result, as when it discloses organic disease; for the cardiac ischemia on which the disease may depend may be brought about by undetectable coronary obstruction or fatty change. On the other hand, post-mortem examinations not infrequently show great sclerosis of the coronaries, and also fatty degeneration, in cases in which the symptoms of angina pectoris had not been present during life; so that it is difficult to determine what is the immediate cause of the angina, *i.e.*, what is the exact causative relation of the lesions to the symptoms.

A very common factor in the production of a paroxysm, or at least a very common attendant upon the paroxysms in the earlier attacks, is a great and sudden increase of arterial tension. Whatever be the underlying organic cause, the immediate action seems to be purely neurotic, just as it is in Nothnagel's vasomotor angina, coming on after exposure to cold, which produces apparently a spasm of the peripheral arterioles and a sudden feeling of tension or severe pain about the heart; or there may be some unknown reflex influence by which the arterial constriction and increased tension are brought about and the paroxysm excited.

It was this sudden increase of arterial tension that led Lauder Brunton, by a happy inference, to try the effect of amyl nitrite in angina. The action of this remedy in causing flushing was first observed by Guthrie, and its power of lessening tension was first shown by Gamgee, but the application of its power to the particular form of increased tension found in angina pectoris was first made by Brunton, with the well-known results of giving deliverance and safety, at least for a time, to many that have seemed ready to perish. In view of the many cases of angina in which great and prompt relief has been given by this agent, I cannot but feel surprised at the opinion expressed by several recent writers that it is doubtful if there are any remedial agents that have the power to arrest or very greatly relieve a paroxysm of the disease. No therapeutic results seem to me more obvious and satisfactory than those that are often witnessed from the use of this remedy in angina; and I fully agree with Professor F. C. Shattuck, that the value of the nitrites in angina is greater than Strümpell, the author upon whom he comments, would seem to admit.

A second form of cardiac pain closely allied in character to the one already considered, and yet distinct from it in its pathologic relations and generally less intense in type, is encountered as a complication of some cases of chronic nephritis, chiefly the contracted kidney or interstitial nephritis. In this class of cases the changes in the kidneys and sometimes in the heart are parts of a general arterio-sclerosis, and the pain in the heart is probably the expression of resistance to the blood-flow through the arterioles.

If it be asked why, with a constantly present mechanical cause, the attacks should be paroxysmal, with intervals between them, it may be said that this is a law of various neuroses, such as neuralgias dependent on pressure, or epilepsies due to exostosis or depression of bone, or spasmodic asthma due to nasal polypi — all conditions in which the causes are constant and the neurotic seizures paroxysmal. In this form of cardiac pain, the attacks may be frequent, but they are in general less severe (such at least has been my experience) than those of true angina connected with heart-lesions. I have described several such cases in a paper read before this Association at its meeting in 1888. In all of them the symptoms of chronic interstial nephritis existed, and in one of them, in which the painful attacks were most severe and most like those of true angina, post-mortem examination disclosed not only chronic contracted kidneys, but occlusion of the coronaries. It is in cases of this kind that potassium iodide in large doses, as advised by Huchard, may sometimes prove beneficial by lessening the arterio-sclerosis. In the painful attacks, a certain degree of relief may be

obtained from amyl nitrite, which, though it cannot reach the organic cause of obstruction, may lessen an incidental increase of tension.

After all, these two forms of cardiac pain may be essentially one in their pathology—both being dependent upon sclerotic changes. Regarded clinically, however, one group is composed of cases in which there are detectable or suspected organic heart-changes, with no kidney complications; while the other group consists of cases in which the kidney-symptoms are always prominent, while the heart may or may not be involved.

A third form of cardiac pain is found in dilatation of the heart, and is perhaps due to tension and stretching of the nerves in the heart-substance. Traube held that the pain of true angina is due to this cause. Whether it be so or not, the subjects of cardiac dilatation frequently experience pain about the heart, greater in degree in general in proportion to the rapidity with which the dilatation is induced.

Pain may thus arise from any form of valvular disease of the heart that leads to dilatation; but of the various valvular lesions it is perhaps found most commonly in aortic insufficiency, which is likely to occasion rapid dilatation of the left ventricle, from the pressure of the backward current of blood from the aorta, at the same time that the left auricle is sending its supply into the ventricle. It is to be remembered, however, that aortic insufficiency may give rise to some cardiac ischemia by the imperfect filling of the coronaries; and thus there may be two causes of the pain, the ischemia and the intra-ventricular pressure. Which has the larger share in causing the pain, it may be impossible to say.

If dilatation be extreme and acutely developed, free venesection may be the best means not only for relieving pain, but also for saving life.

In all forms of cardiac pain, arsenic is a remedy of much value, from its action as an anti-neuralgic, and from its power of promoting the nutrition of the heart. It has no effect in the way of controlling existing pain, but it may lessen the severity and the frequency of future attacks, and I hold, with Anstie and with Balfour, that there is no more important prophylactic tonic against cardiac neuralgia than arsenic.[1]

Looking at all three of these forms of disease and endeavoring to coördinate them as to their cause, it is quite possible that the chief factor in the production of pain common to all of them is pressure brought to bear upon the cardiac nerves or upon the cardiac ganglia themselves. The connection between these ganglia and the cervical and brachial plexuses gives a ready explanation of the extension of the pain to the arms that may occur in any form of cardiac pain. In the first or strictly paroxysmal form, true angina, the pressure may be occasioned by the sudden tension of the arterioles; in the second form, by the general sclerotic state of the vessels; and in the third form, with dilatation of the heart, by the attenuation of the heart-walls.

ORIGINAL ADDRESS.

ADDRESS ON GENERAL MEDICINE.

BY ALBERT L. GIHON, A.M., M.D.,
MEDICAL DIRECTOR UNITED STATES NAVY.

Delivered before the American Medical Association, at Detroit, Michigan, June 9, 1892.

IN accepting the invitation to fill the breach caused by the illness of your appointed speaker on General Medicine, I can but feel that I have imprudently undertaken a weightier task than, at the time, I fully realized. The very flattering terms in which the appeal was conveyed left me no option to decline, and blinded me to the responsibility I was assuming in agreeing to address this great body of experts in medicine on the vital issues involved in the address expected. Hence, I can only ask your indulgence for my shortcoming in begging you, who lead busy lives, to reflect how impossible it is to do in a few short days what is rightfully the careful, deliberate work of preparation for a whole year. What I say, therefore, shall only be in the way of desultory comment on medicine in general, instead of a systematic digest of the year's achievements in the practice of our art.

To me the most gratifying outcome of the year is not the announcement of new therapeutic means, nor the publication of nosologic novelties; with these you are more familiar than I am, for the search-lights of the medical press now leave no dark corners where men may dig and delve for hidden treasures with which, some unexpected day, to startle the world and bring them fame and fortune. He who works to-day stands in an amphitheater, with the whole profession looking and listening, condemning or commending, through their accredited representatives, the fraternity of medical publicists of every nation; and here, as your reporter of the doings of the year, I find it a very pleasant duty to congratulate the profession on the higher standard of medical editorship, which is becoming our national characteristic. Fervid ambition still impels tyros in authorship to engender premature offspring, but, as with all man's progeny, only the fittest survive; we have a body of stalwart adult and veteran periodicalists, who do their work of enlightenment masterfully and in friendly concurrence. If there be any in this assembly who have not studied these living text-books of our science, day by day during the past year, how idle it would be for me to seek to cover their indifference and neglect with the veneer of a twenty-minute random *résumé* of a few prominent occurrences. Perhaps I can perform part, at least, of the duty imposed upon me in no more practical way than by seeking to awaken in the medical body politic a livelier consciousness of some of its obligations outside of the routine duty of the general practitioner.

One of these obligations is the earnest countenance and substantial support of its organs of intercommunication—not merely by subscribing for them, but by contributing to them the results of individual observation, experience, and research, that all mankind may profit by them. Only with such generous and general support can any medical editor, independently and impartially, fill his waste-basket with the crudities and spurious offerings that are poured upon him, and thus become in fact the censor and preceptor the press assumes to be. Eminent distinction in medical, as in secular, journalism is the reward of pronounced merit. Its office requires the highest order of ability, the broadest culture, the widest range of information. If other specialties be the hands and eyes of the profession, this is the silent, thinking brain, which in vaulted attic, away from active participation in the world's affairs, reflects the impulses that go to make up healthy, active life. Without statistics of circulation, I am confident it would be found, as indicating intellectual progress in medicine, that medical periodicals are more widely read and their contents more carefully scrutinized, while their editorial leaders, notes, and criticisms are more independent, fearless, and unbiased. It is enough to enter a physician's office and scan the periodicals—for there should be more than one—upon his table, to judge of his own mental and professional development.

But if a higher order and wider circulation of current medical literature be indicative of the better self-instruction of the adult practitioner, we have reason to congratulate ourselves upon another sign of the medical progress of the day in the reform of the system of the scholastic education of the young entrants in the profession. It is not necessary to detail here what has been done in this direction. The medical press has fully recorded, while it has advocated and encouraged the advance from the old two full courses, dovetailed with the nominal three years' office instruction of our early days, to the splendid system that finds its fullest expansion in this current year. A minimum of three full courses—in many schools four—and these consequent upon prerequisite academic or collegiate tuition, expressed in one university in no unmistakable terms as six years of continuous college tuition for the intending physician, is a prouder achievement in medicine in this year 1892 than all the additions to its pharmacopeia or all the refinements of its therapeutic theories.

The seven grave and reverend professors of our school-days sit still enthroned on their several chairs, but on loftier eminences, for surrounding them are other seven and more to aid in the tasks that have outgrown their own individual capacities. College faculties have grown apace with medicine, and twenty, forty, sixty, more than a hundred busy teachers stand ready to fill with oil the lamps of those that would see far into the mystery of human existence. All the schools have not gone thus far, nor are all the periodicals such grand exemplars as make their own abilities the sole measure of what is fit or unfit, but there are enough of these great beacon-lights in the North and East—at the fountain-heads of our science at the Metropolis, and at that old Quaker City where medicine was early dignified—in the West, and at the farthest South, to attract within the glory of their brightness all whom it were worth attracting. A few years more and it shall come to be an opprobrium not to have been a graduate of one of these real schools of medicine. That this fulfilment may be hastened, it becomes the duty of every member of this body—which should be every member of the profession—by reason of his own lack of early opportunities; by the years he has had to sacrifice to accomplish what he may have done, and often superlatively well done; by his own comprehension of the sublime greatness of this unrivalled science of Medicine, in which, however old we may be, we can have travelled but a little way—to bear testimony of his appreciation of the increasing immensity of the task devolving upon those who succeed us, and to guide these successors of ours where the light is brightest, the road broadest, and the far-off end ever clear in view. He shall serve medicine best who shall see that the young laborer is best equipped for his life-work by natural aptitude, by proper preliminary training, and by a thorough understanding; light and wide and straight as the way may be made, it is long, toilsome, and up-hill before the highest eminence be reached, beyond which still the overhanging firmament ever defies approach.

But a medical man has not done all his duty in supporting, contributing to, and digesting one or more medical periodicals, however able and meritorious, and in advocating schemes of higher medical education. The physician ought not to isolate himself from active participation in the affairs of the community in which he lives, or of the guild to which he belongs. He should manifest his pride in his vocation by encouraging the congregation of all who share it with him in professional societies, both after the American system of municipal, county, State, and National organizations, and in the special associations of those distinctively kindred pursuits—and this not in the trade-union spirit, for mere mercenary ends—but to promote harmony, good-fellowship, and the mutual improvement of men engaged upon the self-same work. While it is not always feasible to leave home and occupation to attend the annual reunions of the great national bodies, it is within the power of every physician to gather together with his professional neighbors—be they but two or three—in friendly concourse. In this American Medical Association are now enrolled about five thousand members and representing about three hundred and fifty societies. Its membership ought to comprise the entire medical profession of America, undivided by schism or sectional interest, and its representatives embrace every State and minor body in the country, with such modification of plan, perhaps, as may bring it more in accord with our American idea of *E pluribus unum*. Without advocating any particular method of accomplishing this object, I only now desire to point the injunction that every graduate in medicine should be in active fellowship with one or more medical associations, whether for individual improvement, friendly intercourse, or social example.

Nor should the pendulum swing too far one way. The doctor should not be only a doctor—else he be deemed in truth but the leech of the caricaturists in semi-clerical garb, with pompous air and gold-headed cane, or the olive-colored garment and Æsculapian badge by which, in recent years, it has been gravely proposed to distinguish him. Social example has a wider field than the

assembly-room of a medical society. The physician should be the first citizen of his commune, peer in education and culture with its highest classes, and leader in all the sociologic and political movements of the day—and this without abating one jot his professional character or neglecting any whit his professional duties. To the young medical man who listens to me, or who may read my words, I would point as the splendid example of the learned physician, who was the exemplary citizen, the active philanthropist, the busy man of the world and jovial companion, as well as the greatest teacher, lecturer, writer, and practitioner of medicine that this country has ever produced—*Benjamin Rush*—and say, Seek to be worthy and useful, honored and respected as he was. Do not bound your horizon by the walls of your office nor limit your intercouse with your fellowmen to interviews with patients and consultations with brethren of the cloth. Everywhere may be seen the first men of the profession sacrificing social amenities and indulgences, and the companionship of their friends and families, upon the treadmill round of office and clinical labor, knowing neither pleasure nor relaxation until the end comes, when the statistician records another unit in the class of early death-rates. In mental occupations, at least, the physician should be omnivorous and polygamous; in the world, and of the world; loyal above all to medicine as his first love, but not blind to other beauties nor deaf to other harmonies. The medical fraternity is singularly reclusive—yet with strange inconsistence chary of hero-worship if its heroes be its own. During the Civil War it was not excelled in loyalty and patriotism. Two of the three founders of the Military Order of the Loyal Legion of the United States were medical men—one happily still with us—and the Grand Army of the Republic was the sole creation of another. The posts of the latter and the commanderies of the former have their full quota of M.D.'s, who had gained their brevets as commanding officers in the field, as well as those who with equal peril and personal bravery rendered their humane offices to stricken comrades. Yet even these men generously applaud successful generals, and remain silent when their own *confrères* ought to be extolled. Within a month I have seen physicians actively canvassing for subscriptions for statues to great military leaders, who have never contributed one dollar to the monument to their own immortal hero, who signed the Declaration of Independence at the peril of his life, who as a member of the Continental Congress braved attainture as a rebel, and who breathed the breath of life into the figure of the new republic whose Constitution he had helped to frame; who died as he had lived, booted and spurred, with his face to the foe, from whom he was striving to protect his fellow-men. This is not the time for me to enlarge upon this strange anomaly of indifference. Besides, it is a sermon I have often elsewhere preached—sometimes, I fear, to unwilling ears.

The intellectual progress in medicine, to which I have alluded as the laudable characteristic of our day, has naturally led to the recognition of preventive medicine as the type of highest medicine; and the fact that I am so committed to this belief made me hesitate to assume the rôle of your annual reporter, lest I trench upon the ground of my friend Dr. Lindsley; for one cannot speak of medicine in this day, without having first of all before him the problem, How can this disease be best averted, which it is our later office to combat? and the more we learn of the nature and cause and history of disease, which the brightest minds are now studiously investigating, the more urgent becomes this problem. I can, therefore, shield my own delinquency behind the assurance that the Address in State Medicine which is to follow, shall cover this very ground.

The discovery of this and that microbic cause, coincident or inevitable consequent of cause, of one disease after another naturally led to the detection of special germicidal agencies for each, and for a time there was an appalling prospect of preventive hypodermatic tattooing, scarcely less repulsive than the disease, and a bravado resolve to let each particular microscopic devil do its worst. Multiplying a million a minute, it was realized that we could be no match for our Lilliputian enemies, when we could not kill by drugs without at the same time killing ourselves. Apace with the bacteriologists' revelations have been the chemists' syntheses, which, however we might be disposed to recommend to our friends and patients, none of us were brave enough to care to take within our own economies. I confess to no intimate familiarity with these latest evolutions of the laboratory, though the names of some I know by sight very well, even if most of them I can neither speak nor spell. Hence it was a gratifying announcement that we had within ourselves our own defenders and defences. "In the blood is the life thereof" began to have greater significance, through the belief that its living cells devoured these countless swarms of intruders, and thus prevented their disastrous inroads.

It was enough for us, then, by tonic and alterative and stimulant and roborant to preserve the appetites of these domestic phagocytes, and see that they were always in sufficient force to patrol the avenues of the circulation. So, the homely phrase of cleansing the blood of its impurities came back like an old friend in a new dress; but already we are called upon to abandon our bio-therapeutics, with its wars of the microbes, and the final victory of good-minded over evil-minded bacteria, as poetic fancy—and now comes the chemist with potencies that are marvellously alike in looks, which set sail on their mysterious voyage in the channels of the blood to neutralize the toxic products of each malefic wound.

Among the pleasantest recollections of my early life are memories of my old preceptor, whose father, himself a favorite pupil of Benjamin Rush, had conferred the latter's name upon his son, which, doubtless, explains my inherited admiration for that wonderful man. I recall how carefully I was indoctrinated with the belief, which I have not been over-ready to abandon, that nosologic nomenclature was a treacherous guide; that diseases were not so many entities for which specific antidotes were to be sought; and that the cardinal points of diagnosis to guide the medical pilot were the grade of action as indicated by the pulse, the state of the secretions, and the condition of the organic fiber. To-day, we go behind these with lens and test-tubes, to ferret the particular microbe, bacterial proteid, or chemical toxine, which has disturbed the circulation, obstructed the flow of the secretions, or irritated, inflamed, or disorganized the basis structure of the tissues.

It would be unpardonable, therefore, in any Address

on Medicine, however cursory and superficial, that one should neglect to give due credit to the bacteriologic investigators, the scope of whose researches embraces not merely the discovery of disease-causation, but the means for its prevention and cure. The busy practitioner, perhaps, has little time to follow diligently the discussions as to whether the bacteria themselves are the real enemies to health, or only the agents for the introduction of their proteid products, or toxalbumins, ptomaïnes, or other chemical toxines, which are the actual pathogeners. He is chiefly concerned as to the practical results of these investigations, and I am fortunately able to lay before you the very latest precise knowledge on this subject, as set forth only a few days ago by that master in this branch of science, my highly esteemed friend of many years, Lieutenant-Colonel George M. Sternberg, Surgeon United States Army, before the Association of American Physicians, at its annual meeting at Washington. I esteem it a high privilege that I am permitted to transmit to you this authoritative statement of the practical results of bacteriologic research.

Until a very late day, admits Sternberg, the bacteriologist's demonstration of the specific cause in a considerable number of infectious diseases had not resulted in the discovery of a specific treatment for these diseases. Preventive medicine has almost exclusively profited by his researches—as when the discovery of the bacterial parasite placed tuberculosis among the infectious diseases, and the destruction of the sputum became a recognized practical necessity. Of the same order are the precautions of modern aseptic surgery and obstetrics—and the use of antiseptics in traumatic infections, and in localized infectious processes. The use of the microscope in the early diagnosis of tuberculosis and diphtheria is a practical result for which the bacteriologist can justly claim credit—as well as the protection of domestic animals by inoculation largely practised in France, and the prevention of rabies in the human subject, even though the specific infectious agent has not been demonstrated.

The chief purport of Dr. Sternberg's valuable paper (which, perhaps, it would have been well for me to have read *in toto* in lieu of anything else) was to present certain late discoveries, which suggest the possibility that we are on the eve of a new departure in the specific treatment of infectious diseases. Sternberg has described 475 species of bacteria, of which 158 species are pathogenic, although all are not differentiated by morphologic characteristics, and the latest discoveries have established the fact that the pathogenic action of those bacteria that have been shown to be concerned in the etiology of specific infectious diseases is due to the formation of toxic products during the active development of the bacterial cells—and to isolate these toxines and toxalbumins is now the attempt.

Recent experimenters, significantly prominent among whom were three Japanese biologists, having demonstrated that the blood of an animal having a natural immunity to anthrax, if injected into the body of a susceptible animal protected the latter from anthrax, it was subsequently found that the blood of animals having an artificial immunity to tetanus or to diphtheria, injected into susceptible animals, in like manner protected these against the effects of the injection of virulent cultures of the bacilli of tetanus or of diphtheria; finally, Dr. Rudolf Schwartz, assistant at the surgical clinic at Padua, reported the actual successful treatment of an advanced case of traumatic tetanus, by injections of *tetanus-antitoxine*, obtained by Professor Tizzoni from the blood-serum of a dog that had been rendered immune to tetanus; and three other cases of success with this same treatment elsewhere have since been reported.

Since Behring's experiments, in Sternberg's opinion, suggest the possibility that the potent toxalbumin of the diphtheria-bacillus may be neutralized in the bodies of infected animals, and the Klemperers have shown the probability that the blood-serum of animals having an artificial immunity to cultures of the *micrococcus pneumoniæ crouposæ*, when injected into other susceptible animals, renders them immune, Sternberg indulges the hope that croupous pneumonia in man may be arrested by a similar mode of treatment. He further says, from analogy based upon experimental evidence, that the successful treatment of tuberculosis appears to call for the administration of *anti-tuberculin* rather than for that of the active toxic principle elaborated by the tubercle-bacillus. Animals that have an artificial immunity to rabies as a result of inoculation with an attenuated virus, owe this immunity to the presence of an antitoxine in their blood or tissue-juices; and Tizzoni and Schwartz, in January of this year, state their belief that the antitoxine of rabies may probably be substituted for Pasteur's inoculations with an attenuated virus, not only with the object of preventing the development of rabies in man after the bite of a rabid animal, but also that it may prove to be curative after the symptoms of rabies are developed.

Ehrlich's experiments with pathogenic toxalbumins not produced by bacteria, but of vegetable origin, Sewall's showing that immunity from poisoning by rattlesnake venom may be produced by injections of small doses of its toxic agent, and others, give strong support to the view that all infectious diseases are due to the action of substances resembling the toxalbumins already discovered, and that acquired immunity to any of them is due to the formation of antitoxines in the blood of the immuned animal; but while in many infectious diseases the toxalbumin is produced by a specific microörganism, we have no evidence that that this is the case in the strictly contagious eruptive fevers, and none to justify a generalization that all infectious diseases, as smallpox and scarlet fever, are due to specific microörganisms. Sternberg suggests the possibility that in these diseases the toxalbumin which gives them their specific character is a product of the living cells of the body of the infected individual, and says the inference is justifiable that the blood and tissue-juices of an individual who has recently suffered an attack of smallpox or scarlet fever contains an antitoxine that would neutralize the active poison in the circulation of another person immediately after infection, and he holds the experiment warrantable to ascertain whether a small quantity of blood drawn from the veins of the protected person would suffice to arrest or modify the course of these diseases. The transfusion of a moderate amount of such blood might be curative, or confer immunity in advance of infection, and possibly an antitoxine may be obtained from the blood of vaccinated calves that would have a curative action in smallpox. Dr. Sternberg has himself demonstrated by recent experiments with the blood of vaccinated calves that

there is something in this blood that does neutralize the specific virulence of vaccine virus, both bovine and humanized.

I can hardly close without a passing reference to the malady that is on every tongue and is credited with the virulence of a plague—the influenza—the influence, whose mysterious grip upon the physically strong and robust, as upon the feeble and frail, leaving all alike mentally and bodily prostrated, has been attributed to some occult cause acting upon or through the nervous system. It, too, is now known to have its bacterium—the latest microörganism to be discovered, unless the verification of the Berliner Hospital experiments shall give that distinction to the alleged bacillus of measles. The bacterial proteid of influenza has not yet been isolated, and when it is, and its antitoxine shall be demonstrated and successfully administered with curative results, a new era shall indeed have begun in general therapeutics.

Certainly, when prevention and cure shall thus go hand-in-hand, the high estate of preventive medicine can never more be questioned, nor that the wise physician's higher office shall be to guard this glorious human body—the crowning work of the Divine artificer—against these enemies from without, rather than wait to undo their malefic work. If we cannot construct the simplest living cell, how can we hope to intelligently reconstruct one?

Granted this, when disease does invade the body, whether by neglect or ignorance, or deliberate defiance of Nature's laws, shall we idly contemplate the evil and do nothing to mitigate, if we cannot wholly eradicate it? While the world endures, man's folly, as well as woman's, shall furnish work enough for practitioners of the healing art, both general and special, and to them a word of felicitation on their share in the progress of medicine toward a higher level.

The intelligent general practioner is the intellectual primate in our profession—not a mere man of all work, ready to do any job after a crude fashion, without much understanding of its *rationale*. Nevertheless, however universal may become the requirements and opportunities and results of higher medical education, it can hardly be expected in this land of unlicensed liberty, that the class of medical tradesmen can ever be entirely banished; and it may be necessary to establish distinctions, as in other countries, even if it be to surrender to them the all-comprehensive title "Doctor." Medical Examining and Licensing Boards are the coarse sieves that do the preliminary sifting, but medical associations must, perhaps, become the means of ultimately determining, by rigid requirements of fellowship, which are the men who stand upon the same level, and this the higher one—and this very higher level is what has given necessary occasion to specialism. The expert specialist is the natural aid to the expert general practitioner—his ally, not his opponent and rival, the body of specialists being the planetary attendants upon the central luminary that animates and impels them, and only subordinate in that each revolves without interference in its appointed orbit, the whole making one system. That this dignified and exalted recognition of the correlation and reciprocal dependence of the several parts of our profession is coming to be the general understanding is, I think, our greatest reason for self-satisfaction at this time.

THERAPEUTIC NOTES.

The Alkaloids of Opium.—In observations upon animals and upon man as to the comparative utility of the various alkaloids of opium, Leubuscher (*Deutsche medicin. Wochenschr.*, 1892, No. 9, p. 179) found that, next to morphine, papaverine exerted the most active sedative influence upon the movements of the bowel. Narcotine was below papaverine in activity. Narceine and codeine proved entirely ineffective. Thebaine acted as an intestinal stimulant. The administration of papaverine in doses of from one-sixth to a half grain, subcutaneously or by the stomach, to individuals whose bowels had previously acted normally, was followed by no constant results. In some persons, transient constipation was induced; in others, no apparent influence was exercised upon the bowels. In adults with diarrhea, the results were not more conclusive. In children, however, better results were obtained, even large doses occasioning no disturbance of consciousness or respiration, of circulation or of appetite.—*Wiener medizin. Presse*, 1892, No. 14, p. 550.

Elecampane-root and Helenine in the Treatment of Leucorrhea.—Parisot (*Essai Thérapeutique sur l'Hélénine : son emploi contre la Leucorrhée*) records the conclusions arrived at from the employment of helenine (obtained from elecampane-root) in twenty-seven cases of leucorrhea. The drug was found to be but slightly toxic. Upon mucous surfaces and atonic ulcers it acted as a local stimulant; in excess, it proved to be caustic. In catarrhal endometritis, daily doses of from a third of a grain to a grain of helenine were followed by improvement in the color and consistence of the discharge, and by its ultimate disappearance. The remedy only acted upon the leucorrhea symptomatically. The primary condition must be treated in accordance with the existing conditions.—*Rev. Gén. de Clin. et de Thér.*, 1892, No. 14, p. 214.

The Treatment of Asthma.—At the onset of a paroxysm, by means of a brush an application of a 5 per cent. solution of cocaine hydrochlorate is made to the nasal fossæ as high as possible, or the nares and throat may for four or five minutes be sprayed with the same solution. Should the attack not be aborted, from six to twelve drops of pyridine on a handkerchief should be inhaled. If the attack has reached its acme, a twelfth of a grain of morphine hydrochlorate is administered hypodermatically, and if necessary repeated at an interval of a quarter of an hour. For the constitutional condition, potassium iodide, belladonna, and arsenic are indicated. In case of emphysema, baths of compressed air should be employed.—Dieulafoy, *L'Union Méd.*, No. 48.

For Chlorosis.

℞.—Ferri et ammonii citrat . . . gr. xv.
Aquæ destillat. } . . āā fʒj..—M.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

Address the Editor: GEO. M. GOULD, M.D.,
1004 WALNUT STREET,
PHILADELPHIA.

Subscription Price, Including Postage in North America.

PER ANNUM, IN ADVANCE . . . . . $4.00.
SINGLE COPIES . . . . . 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, JUNE 18, 1892.

THE AMERICAN MEDICAL ASSOCIATION.

AT its Forty-third Annual Meeting, in Detroit, decidedly "REPORTS PROGRESS." The venerable DR. DAVIS frankly said that in all respects it was the best meeting the Association had ever held:

First, because of the unexcelled hospitality of the profession and citizens of Detroit. Never before has a whole people seemed so pleased to open doors and hearts to so many visiting friends. In some respects there was a true embarrassment of riches, and in one unfortunate instance there was a failure in understanding—whose fault now matters not—whereby the notification of a most charming entertainment offered the visiting ladies completely failed to reach them, resulting in a double disappointment to would-be hosts and willing guests. The Reception Committee, with DR. CONNOR (who has the love and honor of all) at its head, must be voted the sincerest thanks of all visitors. And it would also seem invidious not to mention the hospitality of MESSRS. PARKE, DAVIS & CO., whose courtesy and bounty must by no means be viewed as due entirely to commercial enterprise.

But more important still remains the solid value of the scientific work done. Everyone agreed that the section work had never been on a higher plane or more thorough. It was a truly remarkable fact that the echoes of the great political contest synchronously going forward in a neighboring city were hardly heard or thought of by this great body of scientific men gathered for a different and, as we believe, a higher and a purer purpose. No allurement, social or political, held the attention from consideration of medical science and progress.

It is impossible that all of the sections should show an equally high achievement, and while none fell below excellence, some, and notably the sections on ophthalmology, surgery, laryngology, and obstetrics, raised the standard of work to a level that future meetings may look back to as models.

But of yet greater and more far-reaching significance was the business and ethical work done in the general sessions. Indications—nay, proofs—were at last emphatically given that the days of the medical politician are numbered, and that the tremendous majority of the members are tired of him and his ways, that they are heartily sick of commercialism masquerading as medicine, and wish to make an end of the everlasting bow-wow and intemperate wranglings altogether too characteristic of the past general sessions, and not entirely absent from those of this year. By the vote to hand over without question the business interests of the Association to an Executive Committee, the members signified their denunciation of the waste of time, of the too great absorption of interest, and of the unseemliness and dearth of dignity of the unwieldy general session.

One other suggestion should be conveyed to those called upon in future to deliver the general addresses: Make the reading shorter! The rush for the doors when a long address is to be read should teach that condensation would hold a greater number of hearers, and insure better attention. Would it not, indeed, be better to abolish the general addresses altogether, or all but one, or let them be confined to the sections in which they properly belong? Section-work is more important than the general addresses, and the demands on the time of the section-worker are becoming so great that the less important factor should give way. There has often been an element of self-seeking and self-advertising in the address that does not square with the new spirit. Work, and not talk, is manifestly to-day's ideal. The manner in which this will be realized is by emphasizing the value of section-work and limiting the interest in the general session. By the delegation of general business to the newly-formed Executive Com-

mittee, mobocracy, wrangle, and general swash are to be replaced by parliamentary government and civilized methods of conducting business. Henceforth the sections are autonomies and govern the general body.

Office and honors should seek the man, and it should be held a positive disgrace for one to commend himself and "wire-pull" to get himself appointed to office of any kind.

Affairs pertaining to the *Journal* of the Association have reached a critical stage. Simply in the interests of good journalism it may be said that nowadays marked ability—editorial certainly not excepted—must be well remunerated. The official organ of the Association should be placed in a unique position, both of trust and power. This it can never have so long as editorial responsibility is hampered by political chicane, and so long as the editor has not power to select, abridge, or exclude reading-matter according to his judgment. If he have not such power he is ruled from without; if he may not be trusted with such power, he is not fitted for his post. The adoption of the plan of publishing accepted papers in separate volumes by each section would make it no injustice to individual members for the editor to be vested with an authority that alone can give him an opportunity to make the *Journal* a fitting mouthpiece of American medicine.

A profound cause for congratulation is to be found in the unanimous indorsement of DR. COHEN'S resolution, sent up from the Philadelphia County Medical Society and the Pennsylvania State Medical Society. This is a sharp, clear lesson to the concoctors of secret nostrums and those misnamed physicians who have consented to become their sales-agents, and especially to those editors of so-called medical journals who sell professional soul and honor with the sale of their editorially-controlled columns to the proprietors of secret preparations.

It is to be regretted that as a body the American Medical Association did not set the seal of its unlimited condemnation upon the KEELEY craze. We well know that it cannot turn aside from its true work of positive science to silence every despicable cur of quackery that may bark at its heels. But in this instance Keeleyism is a national disgrace, and we have a duty to the community and to the future that must not be shirked. All honor to DR. DEWEY, and especially to DR. MOVER, for plain, true words manfully outspoken at an opportune hour.

There yet remains the unhealed wound, the division of the New York State Medical Society. What should be the final decision of the committee appointed with the evident purpose of promoting "secondary union," it is not fitting at present to say. If peace is to be the outcome, let it be "peace with honor." It is unjust to both sides to look for a compromise of principles that must leave the vital question at issue really undecided.

Divested of all accidentals and non-essentials the question is simply, May a physician in good standing consult with an irregular, especially with a homeopath? The position of THE NEWS has been freely expressed. So long as the irregular limits his therapeutic practice to any special law except the law of the cure of disease, it is simply useless to advise with him; no result can come of it. It is dogmatism and unscience to pretend that disease can be cured by only one law, whether that be allopathic, homeopathic, or what not. The true physician aims to cure by any means whatsoever, and he is not a physician who cares more for the method of cure than he does for the fact of cure. But beyond this, of course, as we all know, is the ethical question involved in consultation with a man who for gain gives lip-service to a therapeutic creed but practises *not* according to his creed. How any committee can make it right to consult with such a hypocrite—allopathic or homeopathic—is beyond the limits of our casuistical understanding.

At the same time we admit that the rights of permanent members of the American Medical Association who retain membership in the New York State Medical Society, but personally respect and obey the law of the American Medical Association, ought not to be abridged. Having become members when their society was in good standing, their personal conduct, not that of their society, should govern their present status.

SOCIETY PROCEEDINGS.

AMERICAN MEDICAL ASSOCIATION.

Forty-third Annual Session, held at Detroit, June 7, 8, 9, and 10, 1892.

(Continued from page 669.)

GENERAL SESSION.

THIRD DAY—JUNE 9TH.

RESOLUTIONS passed by the Pennsylvania State Medical Society denouncing the insertion of patent-medicine advertisements in medical journals, and especially in the

Journal of the American Medical Association, were read by the Secretary. The resolutions also criticised the practice of members of the profession giving certificates of indorsement to proprietary remedies. The reading of the resolutions was greeted with applause and they were heartily indorsed by the convention.

DR. WILLIAM PEPPER, of Philadelphia, was presented by President MARCY, and as President of the coming Pan-American Medical Congress, he briefly addressed the convention on the importance and plans of the Congress. He expressed the hope that the Congress would promote good feeling and aid in the dissemination of medical knowledge over the Western Hemisphere.

A resolution was passed thanking the Hon. John Sherman and members of the Senate Committee on Foreign Relations for securing the passage of a bill favoring the Congress.

President MARCY announced the following Committee on Revision of the Code of Ethics: Dr. H. D. Holton, of Vermont, *Chairman;* Dr. H. D. Didama, of New York; Dr. Dudley S. Reynolds, of Kentucky; Dr. D. A. Nelson, of Illinois; and Dr. Benjamin Lee, of Pennsylvania.

The President announced the following committee to confer with a committee from the New York State Medical Society concerning the relations of the members of that Society with the American Medical Association: Dr. N. S. Davis, of Chicago, *Chairman;* Dr. J. H. Rauch, of Illinois; Dr. W. T. Briggs, of Tennessee; Dr. D. S. Reynolds, of Kentucky; and Dr. W. P. King, of Missouri.

A resolution directing the attention of the Trustees of the *Journal* to the fact that the Code of Ethics prohibits all commendatory mention or advertisement of secret preparations, and instructing the Trustees to respect such prohibition in the future conduct of the *Journal* of the Association, was passed.

The Trustees reported that they had held four meetings during the year, there being an unusual amount of business to attend to. The schedule of rates of advertising in the *Journal* had been increased more than 100 per cent. The board contemplates a number of changes, among them the cessation of paying commissions on subscriptions. The *Journal* has been enlarged, but from the increase in the advertising patronage it is thought a press and a folding machine can be bought, so that the *Journal* will be printed entirely with its own type and machinery. A balance of $1797.43 remained on hand after all indebtedness had been paid.

The Treasurer, DR. RICHARD J. DUNGLISON, of Philadelphia, reported a balance of $3076.48 on hand.

The Librarian, DR. GEORGE W. WEBSTER, of Chicago, reported that he had received during the year 1200 medical journals, pamphlets, etc. He had an offer from the Newberry Library of Chicago to bind and render accessible a large amount of material belonging to the Association and stored away in Washington. The Library offered to hold the books in trust and turn them over to the Association on demand. The Librarian was instructed, by resolution, to enter into a satisfactory arrangement. Members of the Association were requested to donate books and other literary matter to the library of the Association.

The Rush Monument Fund Committee reported $3000 on hand, and made an urgent appeal for more funds.

On motion of DR. REYNOLDS, of Kentucky, the Secretary was instructed to send copies of a resolution endorsing the efforts of the American Medical College Association in advancing medical education, to the medical colleges, journals, and societies.

DR. TONER, of Washington, called the attention of the Association to the fact that the centennial of the discovery of vaccination would occur May 14, 1896, and offered a resolution that a committee of five be appointed to arrange for a proper celebration of the occasion; that one day of the session of 1896 be set aside for the presentation of papers pertaining to the celebration, and that, if possible, the Association meet that year in Washington, so that the exhibits and documents on the subject of vaccination will be available. The resolution was unanimously adopted.

DR. A. L. GIHON, Medical Director United States Navy, delivered the Address on Medicine. (See p. 692.)

FOURTH DAY—JUNE 10TH.

On motion, the Paddock Pure Food bill was tabled.

DR. R. HARVEY REED, of Ohio, as Chairman of the Committee on Incorporation, reported that the committee desired further time, and invited members of the Association in favor of incorporation to appear before the committee and state their reasons. Further time was granted.

A motion to constitute a Section on Benevolence was tabled.

A motion to constitute an Orthopedic Section was laid over for one year, in accordance with the Constitution.

On motion of DR. R. H. REED, a committee of five was appointed by the Chair to audit the accounts of the Rush Monument Committee.

The committee appointed last year to consider the resolutions of the West Virginia State Medical Society concerning railway and contract surgeons reported that it had made an exhaustive study of the subject. As nearly as could be ascertained there are about 6000 railway surgeons in the country, of which 1200 are members of the Association of Railway Surgeons. The committee had found it true that railway surgeons often took charge of cases regardless of ethics or of the rights of the physician first called, or of the family attendant. True, the patient, if conscious, had the right to choose his own attendant, but the railway company said to him, If you do not take our surgeon you must pay the bills. The railway company had no right to force their surgeon on the patient, nor had the patient the right to force his surgeon on the railway company. That many railway surgeons worked for inadequate pay the committee found a fact. The committee considered the evil too strong to attack without vigorous measures, and recommended that the Association discourage it and endeavor to prevent it from growing worse. The report of the committee was received and adopted.

DR. C. A. L. REED, of Cincinnati, offered a resolution amending the Constitution so as to admit to membership physicians of Canada and the British North American provinces. The resolution was laid over for a year.

A motion that after July 1, 1897, no one should be admitted to membership in the Association unless he had studied medicine for four years, was laid over for a year.

The report of the work of the Judicial Council was made by its Chairman, DR. JAMES F. HIBBERD, of Richmond, Ind.

The Nominating Committee recommended the following officers for the ensuing year:

President.—Dr. Hunter McGuire, Richmond, Va.

Vice-Presidents.—Dr. H. O. Walker, Detroit, Mich.; Dr. Hawkins Brown, Hustonville, Ky.; Dr. Henry Jones, Watertown, Conn.; Dr. Jessie Haines, Sacramento, Cal.

Treasurer.—Dr. Richard J. Dunglison, Philadelphia.

Secretary.—Dr. William B. Atkinson, Philadelphia.

Librarian.—Dr. G. W. Webster, Chicago, Ill.

Trustees.—Dr. Alonzo Garcelon, of Maine; Dr. Patterson, of Washington; Dr. Leartus Connor, of Michigan; Dr. Perry Millard, of Minnesota.

Judicial Council.—Dr. Cartilidge, Kentucky; Dr. Didamer, New York; Dr. Roberts, New York; Dr. Morris, Baltimore; Dr. Emmert, Kansas; Dr. Davis, Georgia.

To deliver the Address in Medicine: Dr. Hobart Amory Hare, Philadelphia. In Surgery: Dr. H. H. Mudd, St. Louis. In State Medicine: Dr. Walter Wyman, Washington, D. C.

Dr. Hugh O. E. Wingate, of Milwaukee, was appointed Chairman of the Committee of Arrangements.

Milwaukee, Wis., was selected as the next place of meeting, on the first Tuesday of June, 1893.

The President appointed the following committees:

Memorial: Drs. Toner, Davis, Didama, Hibberd, and Wood.

Rush Auditing Committee: Drs. Shoemaker, Berry, and King.

Committee of Conference with Canadian Profession: Dr. C. A. L. Reed, Cincinnati; Dr. W. E. B. Davis, Rome, Ga.; H. O. Walker, Detroit, Mich.; Dr. J. P. Lindsley, Nashville, Tenn.; Dr. Leartus Connor, Detroit, Mich.

The Address on State Medicine was delivered by Dr. J. P. Lindsley, of Nashville, Tenn. He reviewed the fatal epidemics at New Orleans, and the benefit to the city of the cleaning up given it by the Federal troops during the war. He then spoke of the epidemics from which Tennessee had suffered. The prevention of disease and its cure he found two very different things. The annual meetings of the American Public Health Association and the Ladies' Public Health Association of New York are great aids in the cause, as are also the magazines of the country. Medical science is fast becoming public property. The Federal Government is, strange to say, the most laggard of all civilized nations in protecting its people from disease.

A vote of thanks was tendered Dr. Lindsley for his address.

A vote of thanks was tendered Dr. H. O. Walker, of Detroit, Chairman of the Committee of Arrangements, to the profession of Detroit, and the Michigan State Medical Society, for the right royal entertainment tendered the Association.

SECTION ON SURGERY AND ANATOMY.

THIRD DAY—JUNE 9TH.

Morning Session.

DR. HERMAN MYNTER, of Buffalo, N. Y., read a paper entitled "Is Amputation Ever Indicated in Coxitis?" He stated that primary amputation is being gradually abandoned for excision. He considered only secondary operation, when the caries has recurred and the discharge has increased. The apparent recurrence is probably only a continuance of the original trouble, and unless the whole of the diseased shaft be removed, even if the wound heal, a useless joint will be the result. Two cases were related to show the benefit of removing all of the diseased structure, plugging the acetabulum with iodoform-gauze, and continuing drainage for some weeks by means of a counter-opening posteriorly to the original incision. In both cases a good, firm, movable joint, with one inch and one and a quarter inches of shortening respectively, was the result.

DR. RIDLON stated that unquestionably in the majority of cases the trouble began outside of the joint, in the bone, and the lack of ability to locate the focus of the disease raised the question as to the wisdom of operating or awaiting the results of local treatment. Of course, if the patient is growing worse, he should be operated on. Unless one can be sure that he will be able to remove all the diseased tissue and cure the case without relapse within the time in which wounds usually heal, it is a question whether the operation and the chances of septic infection should be taken. Dr. Ridlon is prejudiced against operation, unless as a life-saving measure.

DR. ANDREWS, of Chicago, thought that in a large proportion of cases, after suppuration has commenced, excision will be the best way out of the difficulty; but this may not be absolutely necessary to life, as has been demonstrated by cases that have done well without excision. Such cases, however, recover more quickly after operation. Dr. Andrews favors increased employment of operative procedures, but there are exceptions to all rules.

DR. MYNTER referred his excellent results to the great care in removing every portion of the diseased tissue. He did not get primary union and did not want to, as he thought the wound did better if packed with idoform-gauze and allowed to granulate.

DR. T. A. MCGRAW, of Detroit, Mich., read a paper on "The Cremasteric Reflex in Varicocele." He stated that the cause of varicocele has never been satisfactorily explained. A peculiar formation of the veins in the vicinity, great muscular action, and excessive venereal excitement are recognized as causes, and yet many men are subject to all of these without having varicocele. Local injuries, rendering the vessels incapable of performing their function in propelling the blood onward to the heart, is undoubtedly a cause. In some persons there is a natural tendency to a varicose state of the veins. These cases may be considered incurable. The assistance given to the general venous circulation by the related muscles is well understood, but the fact that the circulation in the spermatic veins is largely dependent on muscular contraction seems to have been forgotten. Every man would have a varicocele if it were not for this contraction. Among the muscles concerned, the cremaster muscles are the chief. They cannot contract without squeezing the blood out of the veins, and this is their true and only important function. The force acts from below upward, and the contraction proceeds probably from the irritation excited in the veins

by their distention. In later life the walls of the veins become more unyielding and can better afford to be without support. A vigorous, young man, putting all his power into some supreme effort, powerfully contracts his abdominal muscles, and if at the same time the cremaster muscles likewise powerfully contract, the blood, shut off, must either burst the vein or stretch it beyond repair. In the one case an hematocele, and in the other a varicocele will result. The cremaster muscle varies much in different men, and in some cases seems to be wholly absent. Cases of varicocele that are ascribed to excessive venereal excitement are probably due to a paresis of the nerves of the cremaster. Though in a few cases of varicocele the cremasteric reflex is nearly or quite normal, in the majority of cases there is decided disturbance in the mechanism by which it is engendered. Dr. McGraw takes issue with those authorities that ascribe to hernia the power of producing varicocele. The following conclusions were arrived at: 1st. That the pathology of varicocele is variable, cases differing from one another, both as regards cause and pathologic conditions; 2d, in one group of cases the fault lies in the walls of the veins, which have become weakened either by injury or from congenital or acquired disease; and 3d, in another class of cases the primary diseases involve either the cremaster or the nervous mechanism by which it is controlled; these cases are marked by a deficiency in the cremasteric reflex.

DR. MYNTER, of Buffalo, asked if the knowledge that the cremaster muscle may influence the production of varicocele would have any bearing on the treatment.

DR. MCGRAW replied that this would depend upon whether or not the varicocele were due to paralysis; if so, electricity might be used; but if the cremaster is wholly absent, removal of the scrotum would be the best treatment. This support, however, cannot make up altogether for the intermittent support of the cremaster muscle.

DR. DE GARMO, of New York, stated that he could confirm two of the points made. He has very carefully watched the effect of pressure as a cause of varicocele and has seen many cases with hernia, but he does not think that either has anything to do with the production of varicocele, even if bad trusses are worn. He could not recall any case of varicocele coming on late in life, and has never seen a case from strain. He had a case of combined hernia and varicocele, which was operated upon by another gentleman for the latter and the hernia was cured.

DR. MCGRAW concluded by saying that his paper had reference only to the pathology. He had refrained from saying anything about the treatment.

The Secretary, DR. F. W. MANN, read the paper on "Visceral Phlebotomy," by GEORGE HARLEY, of London, Eng. Two illustrative cases were reported. In the first case the liver was punctured to a depth of eight inches in a patient dying from the combined effects of a greatly enlarged, hard, and inflamed liver, ascites and marked anasarca. Recovery followed, with no return of the disease. In the second case, the liver, enlarged and inflamed, and the seat of strumous abscesses, was likewise punctured. A copious hemorrhage took place through the bile-ducts into the intestine. The liver became smaller. A perfect cure resulted. Pulmonary phlebotomy is the most difficult form of visceral phlebotomy, the constant movement of the lungs making it difficult to close the wound; but it has been done with great benefit to the patients. Dr. Harley recommended the performance of visceral phlebotomy on every accessibly situated internal organ in preference to leeching and cupping.

DR. F. J. THORNBURY, of Buffalo, read a paper on "Advances in Aseptic Surgery."

Afternoon Session.

DR. C. E. RUTH, of Muscatine, Ia., read a paper on "Gunshot Wounds of the Cerebrum," in which he reported several cases demonstrating that, contrary to the generally-accepted idea, a bullet in the brain can be probed for and successfully removed, and that, with careful and delicate manipulation, there is no excuse for puncturing the normal brain-tissue in the search for a ball. Several instruments were exhibited that had been made especially for this department of brain-surgery. As a result of operations and experiments in this line of work, the following conclusions were reached: 1st. That a ball can be followed in its course through the brain; 2d, having been followed to its point of impact on the opposite side of the skull, a trephine disc should be removed, drainage be established, and the ball removed, if possible; 3d, that that probe is best that gives the greatest resistance to penetration, with the least possible lateral friction on its shaft by the collapsed canal; 4th, that a hemispherical front porcelain-tip and an aluminium shaft answer the indications for lead-detection (resistance if of proper size, weight, etc.) required in a probe, better than anything else; 5th, that one intending to follow balls through the brain should thoroughly familiarize himself with the resistance that the normal brain offers to penetration by the probes he expects to use, that he may know when he is applying force within safe limits; 6th, that he should frequently grasp and remove balls and pieces of bone with the forceps of his choice, on the cadaver, before attempting it on the living human subject.

DR. EDWARD MARTIN, of Philadelphia, read a paper on "Air in the Veins," based on experimental work on dogs and monkeys. It was found impossible to have an animal aspirate air into the veins. Even by opening the jugular vein of a dog, and creating a vacuum in the chest, it was impossible to have air sucked in, owing to the collapse of the vein; though if the vein be hardened by disease or artificially prevented from collapsing, the entrance of air is possible. Even if a few bubbles were aspirated, it did no harm. In the monkey, however, the result was quite different, the animal dying in thirty or forty minutes when air was aspirated. In the human being, aspiration of air is one of the most dangerous events that can happen. Dr. Martin related that he had once wounded the axillary vein, and two or three times heard a suction-sound. He was convinced that this was due to air in the tissues and not in the vein, as no evil consequences followed. In the principles of treatment, no advance has been made over the suggestions contained in the writings of Senn. When a vein is opened, the treatment is simply mechanical, and consists in controlling the circulation from the wound to the heart.

DR. B. MERRILL RICKETTS, of Cincinnati, presented a report of a "Case of Talipes Equino-varus." A boy, fourteen years old, fairly well nourished from time of birth, presented talipes equino-varus in a most aggravated form.

The foot was turned straight backward, so that the weight of the body came directly upon the astragalus. As a result, the plantar surface of the foot was thrown upward to such a degree that the under surface of the toes was the only part that touched the ground in the erect posture. It was stated that the left foot at birth had been in as bad a condition as was the right, but by manipulation the deformity had been corrected.

Upon examination it was found that the ankle-joint of the left foot would allow of more than a normal extent of motion in all directions.

In the operation antiseptic precautions were taken. A Barton's bandage was applied, to make the operation as bloodless as possible. An incision was made from the lower extremity of the fibula in the direction of the lower extremity of the tibia, exposing the ligaments and tendons of the joint. These tissues were not divided, but crowded aside to facilitate the removal of the astragalus, which was found greatly deformed, having lost its outlines. An attempt was then made to bring the toes forward to their normal position, but not successfully. The little remaining part of the Achillis tendon being very dense, it was necessary to divide all of the tissues posteriorly, before the foot could be brought forward to its normal position. The plantar fascia was so dense that it had to be divided in order that the foot could remain in its normal position. The foot was retained in position by means of straps, which it was found exerted too much pressure, so that they were removed at the expiration of the fourth day.

The temperature remained below 100° after the tenth day; on one occasion having reached 104°. Recovery was thence uninterrupted, the foot keeping its normal position without support. The boy was on crutches at the expiration of four weeks, and left the hospital at the end of ten weeks. A shoe is now worn, and he goes about with the aid of crutches.

DR. RIDLON, of New York, stated that there are certain cases of congenital club-foot that could not be cured without excision of the astragalus, although some claim that all cases can be cured by stretching and dressing, and others claim that all can be cured by tenotomy. He related a case in which both of these methods had been carefully employed without success. Finally, the astragalus was removed and found to be wedge-shaped posteriorly, which accounted for the difficulty in keeping it in place. The result was perfectly satisfactory.

DR. SAYRE, of New York, stated that he would not go so far as to say that all cases of club-foot could be cured without removal of the astragalus, but he had never seen a case that required excision. Even if the astragalus is distorted, the bones are at first soft and malleable, and if the foot is put in the correct position they will be moulded. He has seen advanced cases in persons of from twenty-six to forty-six years of age, who had been without treatment since childhood, and had always found that section of the ligaments and all holding soft tissues, combined with great force in putting the foot in the normal position, had been sufficient. No case should be considered cured until it can be retained in position without apparatus. Something may be said for operation if the patient cannot afford the time for the slower treatment.

DR. B. MERRILL RICKETTS, of Cincinnati, read a second paper, entitled "Amputation of Scrotum and Circumcision." He reported the case of a white American, twenty-two years old, well developed, both mentally and physically, of nervous temperament, without syphilitic taint, or predisposition to tuberculosis, whose scrotum and prepuce were enlarged and much thickened. The parts were covered with papillomatous growths, varying in size from pinheads to that of a large pear, with also an occasional angioma. The right leg was also covered with these growths. A bandage had been worn on the leg for a long time. Upon removal of the bandage the leg would immediately swell to twice its normal size, with a characteristic glistening appearance. It was thought that if these growths were disturbed, or the skin punctured, an exudation of lymph would take place, and from five to thirty ounces escape. This fluid was of the color and consistency of thin cream, slightly tinged with blood. It was bitter, and crystallized on evaporation.

The man gave a history of having, at the age of eighteen months, an abscess in the right groin, from which time his trouble dated. Every year he would have from three to four chills, followed by a rapid rise in temperature, which would range from 103° to 104.2° for from twenty-four to forty-eight hours. These attacks were preceded by enlargement of the limb, loss of appetite, glassy eyes, inactive mind, constipated bowels, and great tenderness in and about the right iliac fossa. The glands in this region were greatly enlarged. Circumcision and scrotomy were advised, and readily assented to. Circumcision was first performed, with the understanding that should it be followed by bad symptoms the scrotum would not be operated on. No unpleasant symptoms appeared, and two months afterward the second operation was performed without any difficulty. During the following year the man had but two or three chills, followed by fever. He gained in flesh, and felt entirely satisfied with the operation. The operation was performed rather as a palliative than as a curative measure.

DR. B. MERRILL RICKETTS, of Cincinnati, also presented a paper entitled "Neurectomy of the Great Sciatic Nerve for Painful Neuroma as the Result of Gunshot Injury." He reported the case of a tinner, twenty-seven years old, who presented a history of excruciating pain for two years, after having been shot through the leg. He had become addicted to the morphine-habit, taking a maximum of fifteen grains daily hypodermatically.

Examination showed that the ball (of thirty-eight caliber) had passed obliquely through the left leg to the inner side, three or four inches above the condyle, anteriorly to the tendon of the biceps, passing upward at an angle of forty-five degrees, and coming out at about the middle of the thigh externally. The patient stated that when shot he perceived the sensation in his toes, and not at the site of injury. He removed his shoe, expecting to find an injury of the foot, but was quite surprised to find the injury higher up on the leg. Within an hour after

the injury the pain was equally distributed over the foot and leg below the knee.

In the operation the necessary aseptic precautions were taken; the man was anesthetized, and a rubber bandage was applied from the toes upward. An incision, four inches long, was made in the median line, encroaching posteriorly on the popliteal space, exposing the nerve, which was found enlarged to three times its normal size for a distance of one and one-half inches. The nerve divided much higher up than usual. This was fortunate, for had the arrangement been normal both branches would have been divided. The internal branch was the injured one. The external branch was adherent to the internal for a distance of three inches. A section was made one and three-quarters inches long, including the entire enlargement. When the section was made the leg was flexed, and retained in this position by means of straps. A drainage-tube was introduced, and the wound was closed by silk sutures. The tube was removed at the end of the third day, and the cutaneous stitches at the end of the fifth day. The temperature rose to 100° on two different occasions, and remained at about 99° during the course of recovery. The pain gradually subsided. The morphine was withdrawn, and small doses of bromide and chloral were given instead. After the twelfth day the man was allowed to be up and around on crutches. He left the hospital on the twenty-second day, remaining free from all pain and the morphine-habit.

DR. GEORGE E. FELL, of Buffalo, N. Y., read a paper entitled "Forced Respiration (Fell Method) per Face-mask and Tracheotomy in Diphtheria." He called attention to an interesting case of diphtheria occurring in a family of four young children, all of whom were taken down with the disease. The first child was given home-treatment and recovered, while the second, under similar treatment, without the knowledge on the part of the parents of the seriousness of the disease, passed to a rapidly fatal condition. Dr. Fell was called and proceeded to perform tracheotomy. The patient, a boy of seven years, becoming unconscious from cyanosis, it was unnecessary to give an anesthetic. Before the operation had proceeded far, the onset of asphyxia was indicated by rapid dilatation of the pupils. Had it not been for the forced-respiration apparatus that had been provided, the patient would have died immediately after the initial incision; it was found necessary before the operation of tracheotomy was completed to apply the forced-respiration apparatus some five or six times after auto-respiration ceased. Subsequently, forced respiration was kept up through the tracheotomy-tube for some time before the patient became conscious. Hydrogen dioxide was freely used in the mouth and nasal cavities with gratifying results, and also to the tracheal incision. Many times, when dyspnea became great, the liquefaction of the membranes in the bronchial incision was brought about by the remedy so as to relieve the patient. In some instances, when this would not relieve the patient, forced respiration through the tracheotomy-tube overcame the cyanosis and enabled the patient to breathe for himself for some period of time. The exudation, however, continuing to interfere with the respiratory process, the patient succumbed some sixty hours after the operation was performed. The case illustrates the value of forced respiration by means of the face-mask in conditions in which membranous exudates interfere with respiration, and in membranous croup and diphtheria; and also the value of hydrogen dioxide in liquefying the exudates in such conditions.

DR. H. O. MARCY, of Boston, by means of stereopticon slides, gave a number of "Illustrations of Methods of Operating in Hernia." These pictures were from the engravings of the old masters, one edition having been engraved as early as 1756. The plates were from Gay, Sir Astley Cooper, Langenbeck, Scarpa, and Bougeray, and the points of interest in each were briefly brought out.

DR. W. H. MYERS, of Fort Wayne, Ind., read a paper entitled "Treatment of Compound Fractures," laying particular emphasis on antiseptic and aseptic treatment. He presented statistics showing the great decrease in mortality since the introduction of these methods. He does not employ drainage. He believes the ideal dressing to be that which affords the most perfect rest; therefore after thorough antiseptic cleansing he closes the wound with protective, applies several thicknesses of bichloride gauze, and then completes the dressing by plaster-of-Paris bandages. These are allowed to remain for fourteen days or longer, unless there are indications to the contrary. Amputation is often too hastily resorted to, and especially is this noticeable along railway lines. The surgeon should remember that upon his decision the future of the patient depends. A case was related in which two and one-half inches of the tibia were carried away. Four pieces of bone were removed and carefully replaced after the wound had been cleansed. An immovable dressing was applied and allowed to remain for twenty-eight days. The patient made an uninterrupted recovery, and his condition was all that could be desired.

DR. RICKETTS, of Cincinnati, stated that he had read two papers in which he took the ground that in cases of fracture the surgeon has a right to make an exploratory incision if there be doubt as to the character of the injury. If, in a case of compound fracture, the dislodged bone can be returned and union be secured, there is no reason why, if there be two or more fragments, the surgeon should not cut down and wire the pieces. In the majority of cases wire should be used to keep the pieces in position.

DR. RIDLON, of New York, stated that he had heard some surgeons say that bones will not unite if the periosteum is not in place. He could not understand why this should be, if, in abdominal surgery, portions of the peritoneum are taken off and nothing is thought of it.

DR. NORTH, of Michigan, related that he had seen a great deal of railroad surgery. He strongly advised against the use of the knife if it can be avoided, even if the products of ulceration flow out of the wound. Even a year afterward an operation can be successfully performed.

DR. RICKETTS, of Cincinnati, added that in operations on the skull the button of bone is returned, without the periosteum, and union takes place.

DR. GRIFFITH stated that he had used decalcified chips of bone, and had bone develop from them, and he did not think the periosteum was necessary.

DR. MCCAUL, of Michigan, related a case of trephin-

ing, in which he returned the button without the periosteum, and the wound is perfectly sealed to-day.

DR. EMMETT, of Iowa, stated that there is no question about bone-grafts growing. He had seen cases in which Senn's decalcified bone-grafts were used with perfect success.

The Chairman, DR. GASTON, stated that his observations in this line confirmed the views to which he had just listened. He related a case of extensive suppuration along the tibia, denuding two-thirds of the anterior part of the bone of its periosteum. Amputation was proposed, but it was decided to wait, and to-day the case promises complete recovery.

DR. EMMETT related a case of which he had read, in which a patient with a seriously injured foot was advised to have it amputated, but refused. Gangrene set in, and the leg had ultimately to be amputated above the knee. The man sued the physician for $5000, claiming that it was the physician's duty to use his own judgment. He won the suit, and the Supreme Court sustained the decision, saying that the physician was liable for damages, as the patient did not know whether the limb should be operated on or not.

DR. NORTH inquired as to the course to pursue if, in spite of every treatment, non-union continues.

DR. DUFFIELD, of Detroit, stated that if the Supreme Court of the State of New York decides that a patient can say he will not have his limb amputated, and then holds the surgeon responsible for not operating, the surgeon occupies a peculiar position. He had always contended that the patient should decide. The best way is to call counsel, tell the patient the decision, and if he refuses to abide by it let him get another surgeon.

DR. RICKETTS, of Cincinnati, replying to Dr. North, stated that mercuric chloride in large doses internally would cause union of the bone.

DR. MYERS stated that he has had good results from sawing off the extremities of the bone and nailing them together. He had seen Mr. Macewen, of Glasgow, after trephining, break up the button into small fragments and replace them.

DR. RIDLON, speaking of non-union, referred to two cases of compound fracture in which non-union persisted, in spite of all the numerous plans tried. His plan was to put the limb in position and hold it there, preventing motion laterally and longitudinally, and then constrict the limb above the point of injury by a band, producing edema about the injured part. The legs were allowed to hang down, and in both cases union was perfectly solid.

DR. MILTON, of New York, related a case of non-union cured by the patient being allowed to use the leg.

DR. GRAVES, of Michigan, thought that cases of so-called non-union were really cases of delayed union.

The CHAIRMAN reported a case of non-union cured by forcibly rubbing the extremities of the bone together so as to excite inflammatory action.

DR. EDMUND ANDREW, of Chicago, read a paper entitled "The Powerful Effect of Sulphonal in Arresting the Cramps of Fractured Limbs and other Reflex Spasms." He stated that he had first observed the remarkable anti-spasmodic power of sulphonal in a case of painful cramps from a recently fractured femur. Fifteen-grain doses arrested the spasms both when the patient was awake and when he was sleeping. In another case, one of slight fracture of the spine, the patient, whenever he fell asleep, was harassed by cramps of the intercostal muscles adjacent to the injured vertebræ. Sulphonal in fifteen-grain doses completely arrested the trouble. As the drug is slow in action, it is best in nocturnal spasm to give it two or three hours before sleeping-time. Eight-grain doses three times a day have given excellent results in nocturnal seminal emissions. Perhaps the remedy would act well in premature ejaculations in copulation. Two cases of obstinate hiccough were arrested by its employment. A gentleman long troubled with nocturnal cramps of the legs and thighs, increasing with age, got relief from fifteen grains taken before retiring. After two months one dose sufficed for nearly a week. In ten weeks he no longer required the remedy. A young man who had sustained a severe contusion of the right sciatic nerve, suffered from a constant painful, jerking motion of the thigh and leg, resembling chorea. Two fifteen-grain doses of sulphonal completely arrested the distressing movements. From the foregoing it seems that the anti-spasmodic power of sulphonal is of more importance than its sleep-producing influence.

DR. BROOKS, of Iowa, stated that he had sustained a fall, resulting in a severe synovitis, which caused sudden spasmodic contractions of the muscles of the leg during sleep. Sulphonal was prescribed and the spasms were relieved from the first.

DR. MURPHY related the case of a pregnant woman who suffered much at night from cramping in the legs. He prescribed sulphonal and nearly always found that only one dose was necessary to obtain relief. He has used the drug in two other cases, with excellent results.

DR. JAMES A. WORK, of Indiana, has a patient to whom he has been giving sulphonal for rheumatism, attended with cramps of the legs at night. The remedy acted admirably, but the question has been asked if there was not danger of the establishment of a habit. It is a relief to know that as the case progresses less of the drug is administered.

DR. J. P. STRITTMATTER, of Philadelphia, stated that he has found the drug useful in the low, nervous form of typhoid fever, accompanied with jactitations. He related a case in which there had been no sleep for six days. Twenty grains of sulphonal were given and the patient slept for twenty-four hours, only being aroused to take food. Recovery was thenceforth uninterrupted.

DR. S. L. MCCURDY, of Dennison, O., read a paper entitled "Amputations in the Light of Mechanical Science *versus* Prothetical Science." He expressed the view, contrary to general teachings, that joint-amputations made better stumps than amputations above the joint. He gave as reasons, 1st, that the broad articular extremities of the bones made the more durable stumps; 2d, the knobs formed by the condyles at the knee and by the malleoli at the ankle, furnish points about which the socket can be adjusted, preventing the objectionable pumping motion of a cone-stump; and 3d, artificial-limb makers can and do make limbs for disarticulations. Dr. McCurdy considers that Syme's operation makes the best and most comfortable stump possible. Sawing off of the condyles and malleoli is a misguided step; every surgeon should do disarticulation if he felt assured the mechanic could fit the stump. Artificial-limb

makers should make their limbs so as to have the bearings upon but four points: 1st, the ankle, as in Syme's; 2d, below the knee, or about the head of the tibia; 3d, the knee; 4th, the perineum.

DR. ANDREWS inquired as to the use of an artificial foot after Pirogoff's operation.

DR. MCCURDY replied that this operation should not be made at any time, but a good foot can be made for this operation.

DR. KING, of Missouri, disagreed with almost every point made in the paper, basing his objections on considerable experience in railroad surgery. He considered the cone-shaped stump the best. The patient is not expected to walk on the end of the stump. He made it a rule, whenever he could, to go above the joint.

DR. CRAIG, of Pennsylvania, stated that he had made a special study of the surgery of the lower extremity, and he agreed with Dr. King. The effect of saving the joint after removing the ball of the foot is to make the man a permanent cripple. Dr. Craig believes that every foot to be removed near the ankle-joint would be better removed half-way between the ankle and knee.

DR. MCCURDY agreed that the proper thing to do, if one has to go above the ankle-joint, is to go several inches above; but he said that he found artificial-limb makers who do make a foot to fit Syme's amputation.

DR. JOHN B. ROBERTS, of Philadelphia, presented a paper on "The Cosmetic Surgery of the Nose." He called attention to the ignorance of the non-professional public on this subject, which leads many sufferers to resign themselves to unsightly deformity. A plea was made that physicians discourage the correction of such disfigurements and undertake operative measures for their relief. Slight operations will often effect an astonishing change in the personal appearance of the patient, and even extensive operations are devoid of danger. No marked scarring occurs if the operations are properly done. Oblique incisions, antiseptic precautions, primary union, and the location of the incisions in grooves of the skin make external wounds unnoticeable. In addition, many of the operations are done within the nose, the interior of which is reached by the nostrils or through the mouth under the upper lip. No cosmetic surgeon will be successful who does not recollect the frequency of tertiary syphilis of the nose. Unless its frequent occurrence is constantly in mind, he may undertake to excise gummata and allow destruction of the nose from syphilitic ulceration. All doubtful cases should be tested with large doses of mercury and potassium iodide. The various deformities of the nose that can be successfully treated, and the means that the surgeon may employ for their correction were described. All sorts of twisted and crooked noses were said to be amenable to properly directed operation. The correction of the sunken and distorted organs due to syphilis was a prominent subject of consideration; and methods of inserting metallic bridges in substitution for the bony bridge were detailed.

DR. ERNEST LAPLACE, of Philadelphia, presented a paper on "Operative Procedures at the Base of the Brain," in the course of which he stated that the base of the brain is contained in three different fossæ, each of which is separate and on a different plane from the others; but each can be reached with the trephine. To open the anterior fossa the trephine must be applied immediately above the supra-orbital arch, at its junction with the temporal ridge.

A set of malleable platinum-wire instruments, flat and wedge-shaped, are used for separation of the dura from the skull, and can be gently pushed over the rugosities of the skull, so as to reach all parts of the floor of the anterior fossa.

For the exploration of the middle fossa the trephine is applied on a line extending from the middle of the zygomatic process to the external angular process of the frontal bone.

The posterior fossa may be reached by applying a trephine immediately above the external occipital crest to the right or the left. This exposes the cerebellum below the lateral sinus. These operations were successfully performed on dogs. The chief advantage resulting from them will be the thorough application of scientific drainage in cerebral injuries, for the brain, being enclosed in a bony box, cannot expand when irritated or inflamed; hence the absolute necessity of a point of least resistance whence drainage can take place. Hemorrhage is to be controlled with iodoform-gauze packing, or by gnawing off the edge of the bone and applying a hemostatic forceps. Strychnine is to be relied upon chiefly to restore physiologic equilibrium. Illustrative of the principles outlined, the case of a boy was reported who ran a fencing-foil under his left eye through the sphenoidal fissure into the brain. Consciousness was lost, and right hemiplegia and aphasia followed. Fifteen days after the accident the middle fossa of the brain was reached by trephining, and the platinum-wire instrument (a miniature egg-beater) insinuated as far as the cavernous groove, a teaspoonful of clotted blood being withdrawn. Improvement soon followed, and the case made a complete recovery. A remarkable feature was the amount of serous oozing from the trephine-opening, giving evidence of the great intra-cranial tension.

SECTION ON PRACTICE OF MEDICINE.

THIRD DAY—JUNE 9TH.

DR. W. W. PENNELL, of Fredericktown, Ohio, read a paper on "The Genesis of Croupous Pneumonia," which will be published in THE MEDICAL NEWS.

The Nominating Committee reported that they had selected the following as members of the Executive Committee of the Section: To serve for one year, DR. H. A. HARE, of Philadelphia; for two years, DR. I. ATKINSON, of Baltimore; for three years, DR. N. S. DAVIS, JR., of Chicago. The report was adopted, and the members named were declared elected.

DR. CHARLES G. STOCKTON, of Buffalo, was elected Chairman, and DR. GEORGE WEBSTER, of Chicago, Secretary of the Section for the ensuing year.

DR. J. M. ANDERS, of Philadelphia, read a paper on "Cardiac Indications and Contra-indications in the Treatment of Acute Lobar Pneumonia." He alluded to the well-known fact that in acute lobar pneumonia the cause of death is usually heart-insufficiency. This failure of heart-power is attributable to the operation of one or all of three etiologic factors. Of these, the effect upon the heart of the ptomaïnes in the blood produced by the growth of the pneumonia-coccus is the most

potent. These toxic substances exercise a more or less pernicious influence in all cases of pneumonia, and in a great many instances are the chief, or even the sole, cause of death. When brought about in this manner, cardiac exhaustion demands the exhibition of salol or other antiseptics, as well as such cardiac stimulants and tonics as alcohol and strychnine. Digitalis is to be recommended only when the pulse becomes very rapid, fulfilling the important indication of facilitating the nutrition of the heart by lengthening the period of the diastole. High temperature should be reduced by the application of cold to the surface, both locally and generally. Such internal antipyretics as phenacetin, antifebrin, and antipyrin are to be eschewed.

The second influential factor in effecting exhaustion of the heart's power is overfilling and consequent dilatation of the right ventricle, associated with congestion and edema of the non-consolidated portions of the lungs. As the right heart is chiefly affected it will require close attention. It was insisted upon that the effect of the toxic matters in the blood on the heart always predisposes to exhaustion of the right ventricle.

The indications, in such instances as these, are to lessen the work of the right heart, on the one hand, and to restore, as far as possible, the heart's power on the other hand. Cupping and leeching are measures designed to remove some of the burden from the right ventricle, and in aggravated forms of collateral fluxion free bleedings from the median basilic vein are to be recommended. Arterial relaxants have recently been highly recommended to accomplish the same object, but with the possible exception of nitroglycerin, which in small doses acts as a cardiac stimulant, they have no legitimate place in the treatment of pneumonia. To support the heart the use of digitalis was advocated, as this drug increases the capacity of the heart for labor. Alcohol in moderate doses is useful, and strychnine in full doses is of the first importance. Inhalations of oxygen are to be employed when cyanosis persists despite the use of the measures mentioned.

The third influential cause of death is the formation of "heart-clot." In lobar pneumonia there is a greatly increased tendency for the blood to coagulate, and cardiac thrombi of large size are of more frequent occurrence than is generally supposed. The formation of such clots is likely to be followed by cardiac exhaustion, cyanosis, and a rapidly downward course to a fatal termination. A feeble right heart and a sluggish pulmonary circulation probably precede and facilitate such formation in many instances. To prevent this unfortunate accident, as well as to aid in resolving the thrombi, the preparations of ammonia, which tend to maintain the fluidity of the blood are to be employed. In addition alcohol, strychnine, and digitalis should be administered. The last, however, should be employed cautiously.

DR. BEATTY, of Kentucky, called attention to the fact that phenacetin is not objectionable as an antipyretic, because it does not affect the heart unfavorably. He thought that venesection is never indicated. He advised the use of ammonium preparations, but thinks that they have no influence upon clots already formed. Digitalis has more value than all other remedies combined, when there is obstruction to the circulation.

DR. TRUAX, of New York, expressed himself strongly in favor of venesection in suitable cases. It is the most valuable agent in overcoming obstruction to the circulation. It will save hundreds of lives.

DR. HERRICK, of Cleveland, expressed his want of agreement with the current theory as to the cause of pneumonia; and stated that upon our belief in the cause will depend our treatment. The antecedents of pneumonia begin in the abdominal cavity—in the organs of digestion and assimilation.

DR. PENNELL, of Fredericktown, Ohio, called attention to the fact that while Dr. Anders believed the cause to be specific, the treatment recommended was non-specific. When the right heart is wearied, he said, stimulation does no good; the heart must first be relieved by venesection.

DR. DIDAMA, of New York, spoke favorably of venesection in certain cases.

DR. MUSSER, of Philadelphia, stated that each case is a study by itself, and may easily require very different treatment than others. The disease is specific and infectious, but there is as yet no specific treatment. The three measures to be employed are cold, bloodletting, and rest. Every case is, however, not suitable for venesection. When in the early stages the respirations become accelerated and the temperature elevated, bloodletting may be indicated, though the physical signs may not indicate extension of disease. Rest is to be secured by careful nursing and the use of opium. Strychnine is at times most valuable. If heart-failure be imminent, nitroglycerin is valuable. Alcohol and ammonia are preferable to digitalis.

DR. W. F. HUTCHINSON, of Providence, R. I., read a paper on "Darwinism and Disease," in which he referred to a number of the remnants of development, such as the coccygeal gland and appendix vermiformis. The different processes of degeneration, he said, are simply vital processes gone wrong. Tumors vary in frequency from lipoma to carcinoma, because that is the order of difficulty of cell-imitation. Hypertrophy and regeneration demand still greater effort on the part of the cell.

DR. E. L. SHURLY, of Detroit, read a paper on "The Analogy between Acute Idiopathic Pleuritis and Acute Articular Rheumatism." He maintained that there is a basis for such an analogy on embryologic grounds. He reviewed the symptoms of the two affections, showing how pleurisy and rheumatism develop under similar circumstances, and yield to the same treatment. In some cases reported in Germany, by Köster, the effusion subsided under treatment with salicylates in from five to seven days. Dr. Shurly referred to cases of pleurisy and acute rheumatism that he has seen develop under similar climatic conditions.

DR. STOCKTON, of Buffalo, referred to a case in which pleurisy, instead of endocarditis or pericarditis, developed in the course of an attack of rheumatism.

DR. ATKINSON, of Baltimore, stated that post-mortem results do not bear out the conclusions announced by Dr. Shurly. Pleurisy *per se* cannot be accounted for on a rheumatic theory. In cases of acute pericarditis there is often found a pleuro-pericardial friction. Possibly, therefore, in cases of supposed pericarditis the lesion may really be one of pleuritis. Doubtless the

association of the two diseases is, nevertheless, more common than has hitherto been supposed.

DR. SHURLY stated that he did not mean to say that all cases of acute idiopathic pleuritis are of rheumatic origin, but he wished simply to call attention to the analogy between the two affections and to their relatively frequent association.

DR. GEORGE E. FELL, of Buffalo, read a paper entitled "Additional Evidences of the Value of Forced Respiration (Fell Method) in Opium-narcosis." He stated that it was now five years since he first saved a life by systematically respiring for a human being by forced respiration, when the methods in vogue at that time were inadequate to accomplish similar results. Since that time, nineteen human lives have been saved by the method, although it has not been generally utilized by the medical profession. Dr. Fell deprecated the statement that any "unskilled person" could perform forced respiration with success, and related an instance in which intelligent physicians, who were not specially acquainted with his apparatus, were unable to use it without instructions. He also stated that the use of the apparatus could be taught to the crews of life-saving stations or to crews on board ships, so that, after proper instruction, it might be utilized in the saving of many lives that would otherwise be lost by drowning. He also refuted the statement as to the similarity of the method first used by him to that used in the laboratories in operations upon animals, and called attention to the fact that there were nine marked points of difference of practical import between the apparatus devised by him for forced respiration upon man and that used upon dogs in vivisection experimentation.

Dr. Fell reported the twentieth case saved, in which a young woman had been rescued by forced respiration after taking twenty grains of morphine; Case 21, in which an old woman died after having taken an excessive dose of gum opium, although forced respiration was kept up for some thirteen or fourteen hours; Case 22, in which a woman had taken forty-four quarter-grain tablets of morphine dissolved in a glass of water, and whose life was saved after some four hours' work by forced respiration; Case 23, in which three ounces of laudanum had been taken by a prisoner with some sweet spirit of niter, life being saved after four hours' forced respiration and the removal of about eight ounces of blood to relieve the intense cerebral congestion that existed; Case 25, in which a gentleman who had been given up by the surgeons at the Fitch Hospital, Buffalo, and who was in a very precarious condition, was saved by the application of forced respiration for about four hours. These cases thus saved, it was claimed, could not have been saved by any other method than the systematic and regular introduction of air into the lungs by forced respiration.

Dr. Fell expressed a desire that reports of cases of forced respiration be sent to him at Buffalo, N. Y., as he desired to make a full report of results at the next meeting in Milwaukee.

The apparatus consists of a double bellows, which keeps up a steady current of air—three or four movements are sufficient for inspiration, and three for expiration. To the bellows is attached rubber tubing. The air is forced into the lungs through a mask, and escapes by a valve connected with the tube.

The paper of DR. M. M. LEAHY, of Chicago, on "Epilepsy," was read by title. It was contended that, although the cause of epilepsy is yet obscure, not less than two-thirds of all epileptics are incurable. In hospital and general practice, both in Europe and in the United States, some measure of success has been obtained from treatment.

If the exciting cause be compression of the brain, or a lesion of the spinal cord, the chances are largely that the former will be followed by softening of the brain or idiocy, and the latter by paralysis, both terminating fatally.

If the patient be the offspring of intemperate, tuberculous, rickety, or syphilitic parents, he may be relieved; the fits may be stopped for months, possibly for years at a time; but the chances are not in favor of a permanent cure.

When, however, the exciting cause is a simple disturbance of some part of the alimentary canal, or of the secretory apparatus, liver or kidneys—an irritation of the pneumogastric nerve—the chances are decidedly in favor of a permanent cure.

The greatest attention should be paid to the idiosyncrasies of patients, no two persons requiring precisely the same medical and hygienic treatment.

The greatest obstacle in the way of permanent relief to those who are curable is an unwillingness to continue treatment sufficiently long. The fits once stopped, both the patient and his friends regard any effort to induce him to continue treatment as a collusion of physician and druggist to defraud him of his money. The fits return, of course, and the physician is held responsible.

Is it Utopian to hope that, at no distant day, it may be possible to convince the State of the necessity of providing ample hospitals where all epileptics may be carefully and scientifically treated, and where all that are curable may be kept until they are cured?

A paper on "Europhen; with Clinical Reference to Europhen and Europhen-aristol," by Dr. JOHN V. SHOEMAKER, of Philadelphia; and another on "A Few Notes on the Mechanical Therapeutics of Osseous and Medullary Lesions of the Spine," by DR. THOMAS H. MANLEY, of New York, were read by title.

SECTION ON OBSTETRICS AND DISEASES OF WOMEN.

THIRD DAY—JUNE 9TH.

Morning Session.

In the discussion of the papers of Dr. Ashton and Dr. McMurtry, DR. G. BETTON MASSEY stated that he had devised a method of electric illumination for the pelvis, by which the presence of pus could be diagnosticated, pus being less translucent than healthy tissue.

DR. JOHNSON ascribed adhesions and intestinal obstruction to bad operating. The pain from such adhesions is often great, leaving the patient worse after operation than she was before. Perfection in diagnosis would avoid delay.

DR. MARTIN advised omental grafts, covering the raw surfaces of stumps, and early bowel-movement, to avoid adhesions.

DR. RICKETTS stated that he had seen good results from strychnine in preventing intestinal paresis.

DR. E. P. DAVIS regarded a knowledge of the behavior of the peritoneum in the presence of substances

used in abdominal surgery of great importance. Experiments have shown that iodoform is least irritating; and next in order is boric acid. The gauze-drain is better than the glass tube; a case was related in which a glass tube, left in the peritoneal cavity, was forced out by the peritoneum. The peritoneum of animals differs from that of the human subject.

In closing, DR. ASHTON expressed the opinion that adhesions are unavoidable. Raw surfaces should not be left. The omental graft and early bowel-movement could not prevent adhesions. Strychnine, in doses of one-fifteenth of a grain, given three times daily, hypodermatically, for several days before and after operation, is of value. The peritoneum of dogs is easily made septic.

DR. MCMURTRY urged early operation in cases of fibroids in which the tumor is soft, grows rapidly, and hemorrhage is excessive.

DR. ERNEST LAPLACE, of Philadelphia, read a paper on "The Microörganisms of the Diseased Endometrium and Surgical Interference." He stated that experiments performed in Koch's laboratory, in Berlin, showed that microörganisms are present in the normal endometrium, as well as in the cervix uteri. In inflammatory conditions the same organisms were detected, but in much larger quantities, not only in the secretions, but also in the mucous membrane proper and in the submucous fibrous tissue. Normally, the microörganisms present seem to do no particular injury, but under the reactionary congestion incident to cold, they develop rapidly, and induce a pathologic condition. The gonococcus of Neisser was found deep in the mucous layer. This evidence points to the necessity of scraping and thorough disinfection for the relief of such a condition, and a subsequent thorough disinfection and sterilization of the parts with the acid sublimate solution 1 : 2000, and then packing with iodoform-gauze. The identity of some of the microörganisms detected could not be recognized; two of them were found to be pathogenic to guinea-pigs.

In the discussion, DR. MASSEY urged the value of electricity in decomposing a mercurial solution applied to the uterus, thus bringing the antiseptic in immediate contact with the tissues.

DR. VANDER VEER urged the importance of thorough dilatation before curetting. He employs the douche-curette, and afterward hot boric acid solution, packing the uterus with iodoform-gauze. In septic cases, if no improvement follows, he would not delay longer than forty-eight hours opening the abdomen.

DR. MORRIS stated that he employs hydrogen dioxide after curetting.

DR. NELSON stated that he dilates thoroughly, curettes, douches the uterus with a hot antiseptic solution, and finally applies iodine.

DR. GORDON stated that he uses the sharp curette, followed by bichloride, 1 : 2000, dilating repeatedly while curetting; he then applies pure carbolic acid. He puts the uterus in a good position to secure drainage.

DR. ASHTON considered disease of the appendages a contra-indication for dilatation and curetting when gross lesions are present and the uterus is fixed; otherwise diseased appendages do not constitute a contra-indication. The sharp curette is used.

DR. LAPTHORN SMITH emphasized the value of the gauze drain.

DR. E. P. DAVIS stated that he had employed injections of creolin and green soap, 10 per cent., with good results in cleansing the vagina before labor. If vaginitis or endocervicitis has existed, one copious bichloride douche should be invariably given after labor.

DR. S. O. GORDON, of Portland, Me., read a paper entitled "Hysterectomy Without Pedicle." He operates by ligating the broad ligament with catgut, severs the ligated tissue, employs the over-and-over stitch down each side; ligates the uterine arteries, and dissects off the bladder and uterine attachment behind. He lifts out the entire uterus and sutures the peritoneum. He reported twelve cases, with a death from secondary hemorrhage two weeks after operation.

DR. EASTMAN presented a record of sixty-five operations performed by his method. He employs his staff to raise the uterus, leaves his silk ligatures long, pulls them down and sews the serous surfaces together. He thinks it exceedingly difficult to cleanse the vagina; he cauterizes the cervix or packs it with gauze. While the Trendelenburg position is useful in some cases, he has noted the following disadvantages: pus and retained secretions in a fibroid uterus may run into the abdomen; in a recent case dropsy of the retinæ followed. In large tumors he applies the elastic ligature, and removes the bulk of the tumor first; then he extirpates the cervix. When skilfully performed, the mortality of total extirpation of the fibroid uterus should not be greater than that of ovariotomy.

DR. VAN DE WARKER would limit total extirpation to selected cases. Many need no operation. Rapidity in operating is essential. Puckering the broad ligament should be avoided, as ligatures are likely to slip. The broad ligaments constitute the only source of serious hemorrhage; if they are secured, the cervix needs no ligature.

DR. MARTIN urged the selection of a method to fit the needs of the case. Total extirpation removes the cervix, which is the center of support for the vagina; hence vaginal fixation of the cervix is best.

DR. NELSON expressed the view that fibroids are sometimes cured by ergot, pregnancy, the menopause, electricity, and oöphorectomy. Hysterectomy requires rapidity of operation; the broad ligament should be ligated in small portions.

DR. JOHNSON stated that he would remove only the diseased portion of the fibroid uterus, leaving the cervix.

DR. BAER stated that he considers fibroids incurable except by operation; patients suffer constantly from them. Operation should be performed in all well-defined cases, if the patient intelligently consents. Total extirpation is to be avoided if possible. The broad ligament should be ligated, and the pedicle dropped. The stump may be left without covering. The cervix should be left, if possible. The stump should not be constricted if dropped.

Afternoon Session.

DR. GEORGE M. EDEBOHLS, of New York, read a paper "On Combined Gynecological Operations." He stated that the tendency of modern gynecology is to progress in a surgical direction. The uncertainties and

unreliability of other methods of treatment, as compared with the results obtained by surgical measures, are proverbial. With the rapid strides forward of surgical gynecology, this contrast is daily becoming more accentuated. Increased confidence in results growing from increased experience and progressive skill will incline the individual operator more and more to trust to surgical resources. Many cases require more than one gynecologic operation to effect a cure. All gynecologic operations required in a given case should at the present day, as a rule, almost without exception, be performed at the same sitting. The patient has a right to expect this from the expert claiming to possess the highest degree of operative skill. That this will be the standard of the near future there seems no doubt.

Success in combined gynecologic operations presupposes first of all perfect asepsis and a not too prolonged anesthesia. The duration of the latter need but very rarely exceed one and a half hours, even in the most difficult cases. Other things necessary are the requisite degree of operative skill and dexterity, sufficient and efficient assistance, a perfect technique in the various operations attempted, and an instrumentarium suitable for rapid work.

Combined gynecologic operations may be divided into two general classes:

1. Combinations into which laparotomy does not enter.
2. Combinations of which laparotomy forms a part.

The expert operator should be able to perform any required combination of operations of the first class within the time limits of safe anesthesia. The same statement holds good of the combinations of operations of the second class into which a *simple* laparotomy enters. When a *difficult* laparotomy forms part of the combination, the patient's interests may occasionally be better served by operating at two sittings.

To cite an example from practice, Dr. Edebohls has a number of times, in cases of complete procidentia uteri performed curettement, amputation of the cervix, anterior colporrhapy, colpo-perineorrhaphy, and ventrofixation of the uterus at one sitting, doing the five operations within seventy-five minutes.

As a result of his experience and success with plastic work he considers total extirpation of the uterus for prolapsus justifiable only under very exceptional conditions.

There is no excuse for a mortality in combined operations of the first class. The mortality of combinations into which laparotomy enters will depend upon that of the intra-abdominal operative interference required.

The paper concluded with a frank recital of failures in combined gynecologic operations.

DR. JOSEPH TABER JOHNSON, of Washington, D. C., read a report of "Five Cases of Ovarian Tumors with Twisted Pedicle; with Remarks." In each case gangrene and septic infection developed, as they did likewise in one case of uterine fibroids with a twisted pedicle. All were incorrectly diagnosticated; all recovered after operation. In one case the movement of a child on the lap of the patient caused the rotation of the tumor.

In the discussion of Dr. Edebohl's paper, DR. CURRIER stated that combined operations are not possible for all operators, and with patients who bear ether badly. In many cases delay is preferable.

DR. MARCY stated that he operates rapidly, and uses animal suture (kangaroo tendon). Recently he removed some silk ligatures that had given rise to the formation of vesical calculi.

DR. EASTMAN stated that if the stumps of the broad ligament are brought down after total extirpation of the prolapsed uterus, prolapse of the vagina will not occur.

DR. NELSON expressed the opinion that abdominal pain arising after sudden exertion in a patient having an ovarian tumor, followed by peritonitis, is a sign of twisted pedicle; an operation should be done at once.

FOURTH DAY—JUNE 10TH.

Morning Session.

DR. A. VANDER VEER, of Albany, N. Y., presented a paper "On the Management of Cancer of the Uterus, Complicated by Pregnancy, with Report of a Case."

He stated that pregnancy and uterine carcinoma are conditions, fortunately, rarely associated. Winckel, Stratz, and Sutgin, in nearly forty-two thousand cases of pregnancies, in three great obstetric clinics, saw but twenty-two cases complicated by carcinoma of the uterus.

Consulting obstetricians see relatively more cases than do general practitioners, and apparently see as diverse results of treatment. The late Dr. Fordyce Barker reported three cases in which living children were delivered at term, the mothers recovering from childbed without serious drawbacks. Other obstetricians of equal skill have seen this complication followed time after time by death of the mother. Puchett saw five of twenty-seven cases die undelivered during labor; nine, shortly after delivery; ten recovered from labor, and in three the results are not stated. Omitting the three cases in which the results are not given, we have a maternal mortality of 58 per cent. plus.

Cohnstein found a maternal mortality of 57 per cent.; Hermann, in one hundred and eighty cases, found a maternal mortality of 40 per cent., 20 per cent. of these dying before delivery took place. To consider the subject more accurately, of nearly three hundred women suffering from this complication, and in labor at end of gestation, 52 per cent. died undelivered or never left their beds. The maternal mortality is not materially lessened by abortion and premature delivery. Sepsis after delivery of the fetus, from absorption of unhealthy and non-cicatrizing granulations, or from retained placenta, is responsible for a large proportion of the deaths; postpartum hemorrhage and rupture of the uterus are responsible for still another proportion. Few that survive the ordeal of delivery live three months.

Are the conditions less favorable for the children? Only 33 per cent. of the foregoing series were born living, and hardly 20 per cent. lived until the mother left childbed.

There is scarcely a condition of disease that presents a darker or sadder image than does this one. The subject, it is to be feared, has not received the attention in text-books and from teachers of obstetrics that its moment deserves. It is necessary to outline the course pursued by carcinoma of the uterus when complicated by pregnancy, in order to form a clear conception of our duty to these cases in the future. The statistics presented show that we cannot afford to wait for emergen-

cies, abortion, septic infection to arise, if we expect to reduce the fearful mortality.

If obstetricians and gynecologists were called upon to state their individual preference for treatment of these cases in two words, it is probable that the larger number would select vaginal hysterectomy, rather than high amputation, total extirpation, or partial excision. Unless exceptional circumstances are present, total extirpation, in operable cases, should be the rule; the operation to be performed at the earliest moment.

So far as treatment goes, carcinoma of the cervix uteri, associated with pregnancy, may be classified in three groups: First, cases in which the disease is confined to the uterine tissue, without infiltration of the vagina, bladder, rectum, or broad ligaments, and the uterus has not reached a size incompatible with vaginal hysterectomy, say up to end of the fourth month of pregnancy; second, cases presenting the features of the first class, except that removal of the uterus by vaginal hysterectomy is precluded, because of the late period of gestation, after the beginning of the fifth month; third, cases at any period of gestation when total extirpation is impracticable.

In the management of the first class, abortion, either accidental or induced, has been shown to be surrounded by many dangers, although it has been successfully employed by a few operators, as a preliminary to vaginal hysterectomy.

In the majority of these cases, high amputation of the cervix brings about abortion, and is even less successful as to final cure than when practised upon the non-puerperal uterus.

Dr. Vander Veer reported the case of a housewife, twenty-seven years old; good family history. She had menstruated at thirteen; had married at fifteen; had three children, aged respectively ten, seven, and five years, with one miscarriage between the second and third children. For a year menstruation had been more profuse and more frequent than previously. The family physician diagnosticated carcinoma of the cervix, an opinion that was concurred in after careful examination. There was also a possibility of the existence of pregnancy. The latter condition was by the patient thought impossible, as none of the usual symptoms of pregnancy had been present. A cauliflower-like excrescence was found protruding very uniformly from the anterior two-thirds of cervix. The growth was not particularly sensitive to the touch, but had a hard, indurated base. The body of the uterus was enlarged to the size of a small orange; the pelvis was apparently healthy; there was no infiltration of the vaginal walls.

Vaginal hysterectomy was performed September 30, 1890. The uterus was found somewhat larger than it was mapped out to be in the previous bimanual examination. The specimen, after removal, showed the cervix to have been completely involved in the growth, the body of the uterus containing a fetus of about two and a half months' development. Microscopic examination of the specimen disclosed a cellular infiltration resembling closely that of scirrhus of the breast. The patient returned to an excellent state of health.

The points of interest in the case are as follows:

There had been irregular menstruation for over a year—hemorrhage, as it were—yet when the disease must have been pretty well advanced, the woman became pregnant. Would this fetus have gone on to full time; could it have been delivered by abdominal section; and what would have been the mother's chances for recovery? The same line of treatment would be applicable to other patients similarly situated, Including this one, there have been sixteen cases of vaginal hysterectomy for carcinoma of the uterus complicated by pregnancy that had advanced not quite to the end of the fourth month, in which the mortality was *nil*.

Briefly the treatment of carcinoma of the uterus may be summarized as follows: In all operable cases, if the pregnancy is not advanced beyond the fourth month, vaginal hysterectomy should be performed at once; in all operable cases between the fourth month and term, as a rule, complete extirpation of the uterus by Freund's method, as modified by Zweifel, should be practised; and in inoperable cases, delivery at term, or supra-vaginal hysterectomy of the pregnant uterus—Porro's operation—should be attempted.

DR. E. P. DAVIS expressed the opinion that in case of Cæsarean section performed for carcinoma, the prognosis for the fetus at from the twenty-sixth to the twenty-eighth week can be rendered favorable by the use of incubation and gavage. If the fetus is at term, the simple Cæsarean section gives better results than the Porro operation. Sepsis may be avoided by packing the cervix and vagina with iodoform-gauze.

DR. ROBERT T. MORRIS, of New York, presented "A Report of Experiments Germane to the Subject of Abdominal Supporters after Laparotomy," recording observations made at various dates after the performance of laparotomy on rabbits, and concludes that the separate structures in an abdominal wound must be sutured separately in order to obtain a well-repaired wound. He found that at the expiration of seven days the peritoneum was so well united as to be as strong as normal peritoneum. The muscular and fibrous structures were practically of normal strength at the expiration of fourteen days, and the skin required four days more for completely firm union.

It is unnecessary to apply abdominal supporters for the purpose of preventing hernia after a patient is up and about, if the surgeon has united the separate structures properly. Dr. Morris stated that he had never had hernia appear after laparotomy in any of his patients, and they did not wear abdominal supporters after they were out of bed, excepting in occasional cases for purposes of comfort. He uses nothing but catgut for sutures and ligatures.

DR. CURRIER stated that he sutures the fascia separately in closing the abdominal wound. He cuts through the rectus muscle, and not through the linea alba. He uses a broad strip of rubber plaster instead of a supporter.

DR. MCKELWAY stated that he found supporters useful in cases in which union was not perfect.

DR. EDWARD W. JENKS, of Detroit, read a paper on "Colpo-perineorrhaphy." In operating he dissects a flap of vaginal tissue up as far as redundancy is observed on the posterior vaginal wall, using sharp-pointed, double-edged scissors. The stitches are introduced one-third of an inch apart; the flap rarely needs trimming; the last stitch purses the flap and completes closure. Dr. Jenks uses silver wire or silkworm-gut, and flat, non-

cutting needles. The flap is lifted, and the needles are brought out in the middle and re-inserted. For hemorrhage silk sutures are passed over the flap. No dressing is required, and few bichloride douches. The external parts are kept clean by means of bichloride solutions.

DR. POTTER stated that he prefers catgut and silkworm-gut.

DR. DOW objects to a purse-string suture, as rectocele is likely to result. He presses back the recto-vaginal septum and does not bury the sutures. He uses a plate and shot in front, and completes the approximation by a superficial catgut stitch.

DR. NEWMAN stated that he had found Tait's operation insufficient in many cases; but more satisfactory in complete laceration.

DR. W. H. MYERS, of Fort Wayne, Ind., read a paper entitled "A Few Considerations on Ovariotomy where Pregnancy is Present: with a Case." The case was that of a primigravida seized with abdominal pain, which obstinately resisted Christian science treatment. Examination revealed the existence of pregnancy complicated by the presence of an ovarian cyst. An operation was successfully performed, the cyst proving to be multilocular. Labor ensued a few days later, and was followed by brief fever. The patient made a good recovery.

DR. POTTER stated that he had performed double ovariotomy in the fourth month of pregnancy; the patient went to term and was delivered spontaneously.

DR. MURPHY related that he had operated successfully on a patient three months pregnant.

DR. E. P. DAVIS expressed the opinion that the drainage practised by Dr. Myers had been unnecessary, and that it is probable that the presence of the tube excited labor and the fever.

DR. MORRIS reported several successful cases of the same kind.

DR. DOW exhibited a double tenaculum for operating on the cervix.

DR. I. S. STONE, of Washington, D. C., presented a paper entitled "My Operative Experience in 'Pus Cases,'" giving the results of observations in a series of twenty-five cases occurring in his service at the Columbia Hospital for Women. Of these, three had died. One died of nephritis (following gonorrhea) that had begun a number of days before the section, and carried off the patient five days afterward. There was no peritonitis, the patient dying of uremia less than five weeks after the first evidence of vaginitis. The second case died of shock, twenty-four hours after section, from inadequate measures for its prevention. The third had serious bowel-injury, without rupture however, but which may have infected the peritoneum. There was some peritonitis, but no fluid in the cavity. The patient died in three days of exhaustion, with distention and obstruction of the bowels. About two-thirds of the cases followed abortion or delivery at term. Septicemia developing four, five, and in some cases even eight months after delivery had given rise to the most serious complications. Intestinal adhesions of longest standing involve great risk to the bowel in their separation. Gonorrhea had caused six large collections of pus, in some cases aggregating more than a pint. These abscesses, it was thought, were of many months' standing, and consent for operation was only given when the patient was *in extremis*.

On motion, a vote of thanks was tendered to the Chairman of the Section, Dr. E. E. Montgomery, for his efficient conduct of the meetings.

The following is the list of officers for the ensuing year:

Chairman.—Dr. John Milton Duff, of Pittsburg, Pa.

Secretary.—Dr. M. B. Ward, of Topeka, Kan.

Executive Committee.—Dr. E. E. Montgomery, of Philadelphia, three years; Dr. Joseph Taber Johnson, of Washington, D. C., two years; Dr. Joseph H. Eastman, of Indianapolis, Ind., one year.

NEWS ITEMS.

The Clinical College of Medicine and Specialty Hospital, of Chicago, has been organized to "supply to students the instruction and facilities for clinical work now obtained only by hospital internes and attendance at post-graduate schools." A suitable lot has been secured, and work upon the buildings is to be begun immediately. The course of study will cover thirty-six months of actual attendance at the College, Dispensary, and Hospital, divided into twelve terms of three months each. The classes attending each term will be limited to six students, and their entire time in the college and hospital will be occupied by practical work and personal instruction in the laboratories, in the clinical rooms of the dispensary, and in the hospital. No didactic lectures will be given. Advanced students will be required to assist in operations and nurse patients in the hospital, so as to thoroughly familiarize themselves with the after-treatment in surgical cases and the various phases of disease to be seen in the medical wards.

The requirements for admission to this college will be of the highest grade. The student must either have received a literary or scientific degree, or pass a thorough examination. Candidates for graduation will be required to present a thesis on original work in some department of medicine or surgery. During the last two terms of the college course every facility will be offered to students in the different laboratories for original research.

Instruction will be given in the following branches (each department to be conducted by a professor, aided by a corps of assistants): Eye and ear; nose and throat; dental and oral surgery; orthopedic surgery; surgical injuries, including fractures; surgery of the head, neck, and thorax; abdominal surgery; rectal surgery; genito-urinary surgery; surgery of the joints, including dislocations; gynecology; physical diagnosis, diseases of the chest and clinical medicine; nervous and mental diseases; diseases of children; dermatology; obstetrics.

The following departments will be taught by demonstrators who will give personal attention to classes of six in their laboratory, practical work, and recitations: Anatomy; physiology; chemistry and toxicology; materia medica and pharmacology; microscopy and histology; pathological histology; general pathology; surgical pathology; pathological anatomy; visceral anatomy; bacteriology; surgical appliances; surgical dressings and asepsis; hygiene and State medicine; medical jurisprudence; therapeutics; massage and

dynamo-therapy; electro-therapy and hydro-therapy; urinalysis; calisthenics.

The Directors are now receiving applications from candidates for professorships and demonstratorships. Further information can be obtained by addressing the Secretary of the Board of Directors, S. A. McWilliams, M.D., 3456 Michigan Avenue, Chicago, Ill., or the President, J. E. Harper, M.D., 1101 Masonic Temple, Chicago, Ill.

The American Climatological Association will hold its ninth annual meeting at Richfield Springs, N. Y., June 23, 24, and 25, 1892. The following papers have been secured:

Address of Welcome, Dr. C. E. Ransome, of Richfield Springs.

Address of the President: "The Element of Change *per se* in the Climatic Treatment of Diseases," by Dr. Willis E. Ford, of Utica.

"The Shurly-Gibbes Treatment of Tuberculosis," by Dr. E. Fletcher Ingals, of Chicago.

"Slow Breathing in Phthisis," by Dr. Carl Ruedi, of Denver.

"Treatment of Phthisis by the Pneumatic Cabinet," by Dr. C. E. Quimby, of New York.

"A Further Report on the Treatment of Phthisis in Colorado," by Dr. S. E. Solly, of Colorado Springs.

"Results of Tuberculin and its Modifications at the Adirondack Cottage Sanitarium," by Dr. E. L. Trudeau, of Saranac Lake.

"Experience with Guaiacol in Treatment of Tuberculosis," by Dr. A. Jacobi, of New York.

"The Use of Tuberculin; a Safe and Important Aid in Selected Cases," by Dr. Charles Denison, of Denver.

"The Hygiene of Bathing," by Dr. F. H. Bosworth, of New York.

"The Classification of Mineral Waters," by Dr. A. N. Bell, of Brooklyn.

"Heart Failure," by Dr. A. L. Loomis, of New York.

"Altitude in Affections of the Heart," by Dr. Frederick I. Knight, of Boston.

"Cardiac Disease Consequent on Epidemic Influenza," by Dr. R. G. Curtin, of Philadelphia.

"Effect of Change of Posture on Heart Murmurs," by Dr. V. Y. Bowditch, of Boston.

Discussion: "The Influence of Bacteriological Investigation on Preventive Medicine."

"Underground Water Currents; Causes and Results of Deflection," by Dr. Leroy J. Brooks, of Norwich, N. Y.

"The Causes of Death in Lobar Pneumonia," by Dr. G. R. Butler, of Brooklyn.

"The Methods of Cooling Water in Hot Climates," by Dr. T. J. Darlington, late of Bisbee, Arizona.

Papers are expected from Drs. James R. Leaming, Beverly Robinson, Clarence C. Rice, John M. Keating, James H. Wroth, and others.

The American Laryngological Association will hold its fourteenth Annual Congress at Boston, June 20, 21, and 22, 1892. The following program has been arranged:

First Day—June 20th.

President's Address, by Dr. S. W. Langmaid.

Papers: "The Present Status of the Treatment of Hay-fever," by Dr. C. E. Sajous. "The Influence of Certain Diathetic Conditions upon the Prognosis in Operations upon the Throat," by Dr. D. Bryson Delavan. "Some Pathological Conditions of the Upper Air-passages Accompanying 'La Grippe' Attacks," by Dr. S. Hartwell Chapman. "Pharyngo-mycosis," by Dr. F. I. Knight. "A Case of Carcinoma at the Base of the Tongue," by Dr. Jonathan Wright. "A Case of Cancer of the Tonsil Treated by Lactic Acid," by Dr. E. Fletcher Ingals. "Report of Some Cases of Membranous Sore-throat," by Dr. Beverley Robinson.

Second Day—June 21st.

"Intubation for Chronic Subchordal Stenosis of the Larynx in a Boy Twelve Years of Age," by Dr. Charles H. Knight. "Rare Forms of Laryngeal Growth," by Dr. Alexander W. MacCoy. "A Case of Tumor of the Larynx," by Dr. H. L. Swain. "Two Cases of Laryngectomy for Malignant Disease," by Dr. J. Solis-Cohen. "The Value of Sprays in the Treatment of Catarrhal Affections of the Upper Air-passages," by Dr. Clarence C. Rice.

Third Day—June 22d.

"Nasal Hydrorrhea," by Dr. C. E. Bean. "An Eligible Method of Repairing a Broken Nose," by Dr. W. H. Daly. "The Correction of Deformity Resulting from Abscess of the Nasal Septum," by Dr. John O. Roe. "The After-results of Nasal Cauterization," by Dr. T. A. DeBlois. "Diseases Incident to the Frontal Sinus," by Dr. D. N. Rankin. "A Case of Suppurating Ethmoiditis," by Dr. J. H. Bryan.

National Association of Railway Surgeons.—Dr. N. Senn, Chairman of the Special Committee on Program for the sixth annual meeting of the National Association of Railway Surgeons, reports the following as one of the topics for consideration: "Injury to the Spinal Cord and its Envelopes Without Fracture of the Spine. 1. History. 2. Experimental Research. 3. Anatomical Landmarks. 4. Spinal Localization. 5. Diagnosis from the Standpoint of the Neurologist. 6. Pathology and Pathological Anatomy. 7. Prognosis. 8. Treatment. 9. Medico-legal Aspects. 10. Statistics of the Amount of Money Paid by the Railroads of the United States during the last Ten Years for Alleged Injuries of the Spine."

Each of these sub-heads is to be considered in a thirty-minute paper, after which the subject will be open to discussion by the entire Association.

Dr. Henry F. Formad, Demonstrator of Pathology and Lecturer on Morbid Anatomy at the University of Pennsylvania, and Pathologist to the Philadelphia Hospital, died June 5, 1892, after a brief illness, at the age of forty-five years. The funeral took place on June 9th.

CORRECTION.

In the tenth and eleventh lines of the second column on page 673 of THE MEDICAL NEWS of June 11, 1892, Dr. Charles Denison is quoted as saying that "in a letter received, Dr. Edes expressed his great faith in the remedy." The name of Dr. Edes was, by mistake, used for that of Professor Koch, of Berlin.

At the top of the second column of page 504 of THE MEDICAL NEWS of April 30, 1892, it is stated that "the price of diuretin (Knoll) is $2.50 per ounce, av." We are informed that since January the price of diuretin (Knoll) has been $1.75 per ounce.

THE MEDICAL NEWS.

A WEEKLY JOURNAL OF MEDICAL SCIENCE.

VOL. LX. SATURDAY, JUNE 25, 1892. No. 26.

ORIGINAL ARTICLES.

THE TREATMENT OF SUPPURATION OF THE KNEE-JOINT, WITH ILLUSTRATIVE CASES.[1]

BY W. T. DODGE, M.D.,

SURGEON TO MERCY HOSPITAL, BIG RAPIDS, MICH.

THIS article is limited to the consideration of the prevention and treatment of suppurative synovitis, and will not include the discussion of epiphyseal osteitis or tuberculous synovitis. The subject of knee-joint diseases, especially the treatment of suppuration, and the prevention of that occurrence after injuries to the joint, is an interesting one to every practitioner, and one that should be thoroughly understood by everybody who practises the healing art. I have no doubt that everyone who has had experience in surgery is sufficiently familiar with the principles of the modern treatment of this affection, but I know that a great many general practitioners, who are thoroughly qualified for the general practice of medicine, make very serious mistakes when suddenly called upon to treat a recent injury of the knee-joint; and many of them are wholly at sea when confronted with a joint full of pus.

I have prepared this paper with the hope of provoking a discussion of this subject that will attract the attention of the general practitioners, who do not see many surgical cases, but who are generally first called to attend instances of simple wounds of the knee, and who may generally prevent the occurrence of suppuration in such cases, if they but apply the principles of aseptic surgery and enjoin absolute rest. As the knee-joint is the largest and most exposed joint in the body, it is very frequently injured, and unless wounds penetrating it are promptly and correctly treated, suppuration is sure to ensue. An incised wound of the joint should be thoroughly cleansed, and closed at once by means of deep catgut sutures. Aseptic dressings should then be applied, and the joint placed at absolute rest for several days. Punctured wounds should be enlarged, thus converting them into incised ones, when they may be treated as such.

CASE I.—Mr. C. L. was admitted into the Mercy Hospital on February 14, 1891, with a cut at the outer and lower angle of the right knee, penetrating the capsule, from which the synovial fluid was freely flowing. The injury had been received on the previous day, and the man had walked considerably subsequently. The joint was much swollen, and he was suffering from a great deal of pain. I washed the wound thoroughly with bichloride solution, and then closed it with deep catgut sutures. The usual bichloride gauze dressing was applied, the joint immobilized by means of a posterior splint, and the patient placed in bed. In three days the wound was found to be healed, and in a week the patient was discharged as cured.

CASE II.—Mr. J., a driver of a delivery wagon, on February 1, 1892, fell on a nail, which penetrated the knee-joint at the outer and lower angle of the patella. He removed the nail, and continued working until the following day, when the great pain and swelling brought him to my office for relief. I introduced a director into the opening made by the nail, and found it to pass directly into the joint. I enlarged the opening freely, and then treated it according to the method described in Case I. The patient had no further pain, and resumed work in one week.

The principles of the treatment of suppurative synovitis are drainage, irrigation, and rest.

The best description of the principles involved in establishing drainage of the knee-joint that I have been able to find is in the *Reference Handbook of the Medical Sciences*, from which I quote: "If the leg be extended and the muscles of the thigh be relaxed, all portions of the joint-cavity are then quite freely communicable with each other. . . . As soon, however, as flexion of the leg is begun, the patella is brought in contact with the articular surface of the femur, and the greater the degree of flexion the firmer will be the apposition of their articular surfaces; so that, when the limb is flexed at a right angle the joint-cavity will be practically, although not completely, divided into two cavities, one behind and below the patella, the other above it. With the limb in this position it is not possible to thoroughly wash out either cavity by way of the other.

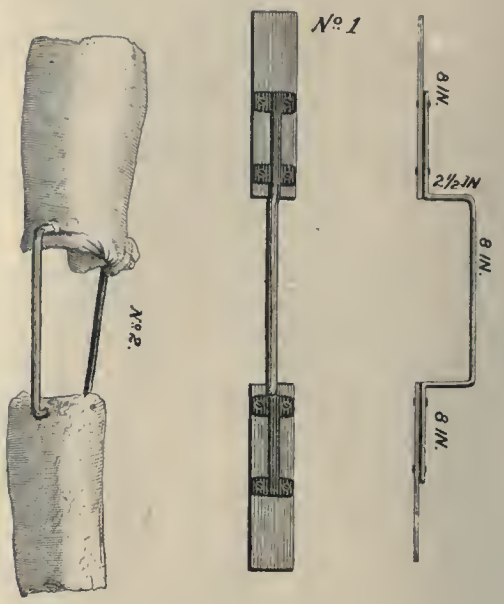
"When the limb is extended the upper synovial prolongation of the joint extends often four or five inches above the patella, beneath the tendons of the quadriceps extensor, and connects with the main joint-cavity by a free opening, which at times is much constricted. As the leg is flexed this pouch is continually drawn down, until, with the limb fully flexed it is located at the upward limit of the

[1] Read before the Michigan State Medical Society, May 5, 1892.

articular cartilage at the lower end of the femur; therefore, when this pouch is to be opened at its uppermost limit the leg must be fully extended. At the posterior aspect of the joint-cavity each condyle of the femur rests in a cup-shaped depression of the ligamentous tissues, and each one should be drained independently. The synovial membrane also surrounds the upper end of the tibia and the lower portions of the outer surfaces of the condyles of the femur, and in the recesses thus formed, unless unusual care be taken, inflammatory products may collect and decompose.

"In order to prepare for the thorough washing out and drainage of the knee-joint, the leg must be fully extended, and through an incision made at one side of the patella the index-finger of the operator should be introduced into the joint-cavity, and pushed upward beneath the patella into the mouth of the submuscular prolongation of the synovial membrane, the neck of which is stretched or divided if it be too narrow to admit the ready entrance of the finger, which is carried beneath the vasti muscles to the uppermost limits of the sac; and at these points the drainage-tubes are carried through to the antero-lateral surfaces of the thigh. The cavity above the patella should be additionally drained by tubes passed into it at either side of the tendon of the quadriceps extensor, close to the upper end of the patella. The remaining part of the cavity is drained through its anterior and posterior portions. The anterior openings are made beneath the ligamentum patellæ, at the apex of that bone. The posterior drainage-tubes are passed between the hamstring tendons and the bones in front, into the posterior condyloid pockets before mentioned."

Irrigation should be thoroughly carried out every day with some antiseptic solution. My preference is for a solution of mercuric chloride of 1 : 2000, but any antiseptic solution will answer. Hydrogen dioxide is a very valuable cleansing agent in this as in all other pus-cavities, and by its use the joint can be rendered free from pus. Rest is procured by some form of apparatus that immobilizes the joint in a straight position and affords opportunity for inspection and treatment. Any one of the several varieties of bracket splints described in the text-books will fulfil these indications very well; but the most simple and inexpensive one that has come under my observation has never heretofore, to my knowledge, been described in print, and was devised by my friend, Dr. H. M. Leach, of Saginaw. The accompanying illustrations give a clear idea of the splints and their method of application to the leg by means of plaster-of-Paris. They can be made in a short time by any blacksmith. They are also very useful in the treatment of compound fractures of the leg. If the fracture is near the ankle, the splints are bent at one end at a right angle and attached to the sides of the foot. It will be seen that when they are in place the limb can be handled, irrigated, and



the dressing applied without causing pain to the patient.

The following cases illustrate the results of the foregoing method of treatment:

CASE III.—A. R., male, aged fourteen years, was admitted into the Mercy Hospital on November 28, 1890. Several weeks previously he had received an injury to his left heel, which resulted in suppuration. I found a bladder of pus hanging from his heel, and learned that he was having rigors and a fever of 105° F. The pus was evacuated and the abscess irrigated, but the rigors continued, and suppuration of the right knee occurred. Two days after his admission, with the assistance of Dr. Burkart, I removed the entire left os calcis, it being completely destroyed by the suppuration, and made free openings into the right knee-joint, irrigated it thoroughly with bichloride solution of 1 : 2000, introduced eight drainage-tubes, and put the leg up in bracket splints. In introducing the drainage-tubes I explored with my finger, and placed the end of a tube in every pocket in which there was any possibility of pus accumulating. The patient had no further rigors, and the temperature came down to 100° F., where it remained several weeks, and then gradually approached the normal. Daily irrigation with a 1 : 2000 bichloride solution was practised, and at the end of three weeks the patient was removed to his home, where the treatment was continued by the family physician, who recently reported to me that both the knee and the ankle had healed perfectly, and that the boy had good use of both limbs, with considerable motion in the diseased knee.

CASE IV.—I saw this patient in January, 1891, in

consultation with Dr. John Snyder, of Mecosta, who has kindly furnished me with the following history of the case. When I saw the patient his physician had established perfect drainage, and I did nothing but approve of his treatment and recommend the application of bracket splints. "Mr. W. H., while chopping, cut into the left knee-joint, just missing the upper outer angle of the patella. He remained in the camp eight days, during which time nearly everything was applied to the wound, including cow manure. He continued getting worse until the ninth day, when he came home and consulted me. He had a temperature of 105° F., with all the terrible depression following a septic inflammation in the knee. The odor of the discharge from the wound was simply indescribable. He had severe pain, especially upon the slightest motion. I made free openings into the joint, introduced three large drainage-tubes, and irrigated with a 1 : 2000 bichloride solution. After this procedure his temperature fell to 101½°, and remained so for three days, when three more drainage-tubes were introduced and the limb put up in bracket splints. The joint was then perfectly drained, and his temperature fell to 99° F., at which point it remained for eight days, when it became normal. The joint was irrigated every other day with the 1 : 2000 bichloride solution. In four weeks the knee was perfectly healed. He can now (March, 1892) walk without a limp, and can bend the joint at an angle of forty-five degrees."

Dr. Snyder deserves much credit for his successful treatment of this serious case, as the difficulties attending the treatment of such a case in a private house many miles in the country are much greater than in a hospital.

CASE V.—H. L., a boy, aged twelve years, on September 1, 1891, received a cut on the left knee with an axe, and was taken immediately to his local physician, who is generally respected as a competent physician, but who has had no experience in surgery. The doctor sewed up the wound without making any special attempt to procure asepsis, and sent the lad home without giving any instructions whatever concerning his future care. The boy continued to move around as usual for several days, when the joint became so much swollen that he was forced to remain quiet. One week after the injury he was admitted into the Mercy Hospital, when I found the joint filled with pus, and the patient suffering from pain, rigors, and a fever of 103°. With Dr. Burkart's assistance, I opened the joint, irrigated, introduced drainage-tubes, and put the leg in bracket splints, as previously described. The improvement was immediate and continuous, and the boy was discharged in six weeks, cured. I examined him in March last, and found him in good health, with a useful leg, the knee-joint being freely movable.

Theodore Meynert, the distinguished alienist and neurologist, died recently at Vienna, at the age of fifty-nine years.

THE VERTIGO OF ARTERIO-SCLEROSIS.[1]

BY ARCHIBALD CHURCH, M.D.,
PROFESSOR OF NEUROLOGY, CHICAGO POLYCLINIC; LECTURER ON INSANITY, ETC., CHICAGO MEDICAL COLLEGE.

THE discussion of a pathologically subjective state is in itself practically impossible, and the difficulty is not lessened when that state is a symptom of many widely-differing conditions, some functional and some grossly organic. To use the term vertigo is therefore undesirable, but for lack of one more definite its employment is a necessity, and in this connection is not open, perhaps, to the emphatic objection that elsewhere obtains. It is in its generic sense that I wish to make use of it.

In a very recent and comprehensive article, Suckling[2] takes up the subject of vertigo, and in a way describes it as the consciousness of disordered equilibration, showing that it may exist from want of harmony in the impressions received from any of the senses, and possibly from the sensibility of the viscera as well; but it is not my present purpose to direct attention to the physiology of equilibration, or to take up the interesting topic of coördination, which is closely associated therewith. Suckling, clinically, classifies the forms of vertigo as aural, ocular, vascular, dyspeptic, nervous, epileptic, toxic, of organic brain-disease, and from reflex irritation, but says nothing specifically of the vertigo of arterio-sclerosis. Most other writers, either on the topic of vertigo or on that of arterio-sclerosis, are equally silent; yet vertigo may be, and often is, as will be urged farther on, a signal symptom of this arterial state, the proper recognition of which may lead to such treatment as will obviate organic disease of the brain, kidneys, liver, and other important structures, and many times definitively prolong life.

It is only of late years that arterial changes have been given the importance in pathology and in clinical medicine that they deserve. The degeneration of senility, the modifications found in gout, rheumatism, chronic metallic poisoning, syphilis, and those associated with alcoholism, chronic nephritis, and many other serious maladies, make it imperative that we recognize at the earliest moment the presence of a change in the artery that may in many instances, in the early stage, be amenable to treatment, but which otherwise soon passes beyond the possibility of medical control. Atheroma is not here synonymous by any means. It is the pre-atheromatous condition with which we have to deal, and it is the vertigo symptomatic of that arterial fibrosis to which attention is directed. As a matter of demonstrable fact, this arterial state is widely and generally disseminated in these cases, but the com-

[1] Read in the Section of Medicine of the American Medical Association, at Detroit, June 7, 8, 9, 10, 1892.

[2] Birmingham Med. Rev., Nov. 1891.

plexion of the disease varies with its local intensity. In some instances a contracted kidney, in others angina pectoris, in others the cerebral symptoms are the prominent feature, and of the brain-symptoms the earliest is vertigo, and the last cerebral hemorrhage or dementia.

When a man, past the prime of life, without any previous serious illness, becomes suddenly faint, has a swimming in the head, a feeling of giddiness, of distinct gyration, of darkness and impending death —one or several of these sensations—he usually at once seeks advice in grave apprehension (sometimes well founded) of approaching cerebral hemorrhage, and usually gets a cholagogue cathartic, or is told that his stomach is wrong, and sometimes is told rightly. But cases are constantly presenting themselves in which such vertiginous attacks are happening at shortening intervals; the patient gives up his tobacco, his spirits, if he is a drinker, cuts down his meat, takes to some of the many waters recommended, has Turkish baths, and gains only moderate relief, or none at all. If he is carefully examined, he will probably present a well-defined tortuous frontal artery, a distinct arcus senilis, a strong, even a clanging, second sound of the heart, sometimes reduplicated, and yield a sphygmogram indicative of increased arterial tension. The pulse may be abnormally slow or arhythmic, the urine scant, and a trace of albumin is not rare. He finds that exertion of a moderate degree precipitates the attack, that he cannot endure a temperature at all above the usual, and often a change of position from recumbency to the upright is the occasion of a "blur" or of giddiness.

The attack itself is, as already indicated, widely variable in different patients. A fulness and throbbing in the head, a feeling of heat in the scalp, and a blur before the eyes are usually mentioned, and at such times marked paleness is noticed, followed, as a rule, by considerable redness of the face. There is a desire to get in the open air, and badly-ventilated or close apartments are unendurable. An habitual smoker will sometimes find tobacco-smoke repugnant. In more severe forms, the patient may stagger, fall, or gradually sink to the ground; he cannot speak for a few seconds, though consciousness is rarely completely lost. The recumbent position is usually sought, or the patient clings to some object, and after a period of from five to twenty minutes the feeling passes away, leaving him rather languid, with an inclination to sleep, and usually mentally depressed and apprehensive. At first, he attributes the attack to anything and everything that in his estimation can cause a departure from health, and usually establishes a close watch upon his diet, habits, and mode of life; is inclined to avoid exercise or exertion of any sort, fearing to precipitate an attack, or to go by himself on the streets—in short, becomes an invalid with hypochondriacal tendencies.

In a remarkable monograph on this subject, Professor J. Grasset,[1] of Montpellier, divides the vertigo of arterio-sclerosis into three forms: (1) Simple vertigo; (2) Vertigo with epileptiform crises; (3) Vertigo with slow pulse and syncopal or epileptiform attacks. Some of the features of the slighter attacks, as already roughly sketched, undoubtedly suggest a similarity to mild epileptic seizures—for instance, the paleness of the face, the oppression and the final confusion, depression and tendency to sleep—but personally I have never encountered well-marked convulsive phenomena reasonably attributable to this cause.

With Huchard,[2] Grasset is in some cases inclined to attribute acquired habitual extreme slowness of the pulse, which, in numerous reported instances, has ranged from twenty to forty per minute, or even less, to the effect upon the medulla of an arterio-sclerosis acting mechanically to lessen the blood-supply to the cardiac centers. As far as I have been able to ascertain, this hypothesis has, as yet, received no positive anatomic or experimental support, though it is seductively reasonable. The bradycardia is almost always marked by syncopal and vertiginous features, and arises in individuals predisposed to or actually the subject of marked arterio-fibrosis.

The diagnosis is often one of extreme difficulty, in spite of a hasty statement to the contrary by a recent American writer. I have known the symptomatic vertigo confused with Ménière's disease by a very competent specialist in nervous diseases; for it may, as in that particular instance, be of a systematized character—that is to say, marked by a sensation of falling in a given direction, or of being rotated in a constant manner to the right or left, and even associated with a suggestive stagger. If to this a little middle-ear catarrh is added, a diagnosis of aural vertigo might be easily reached, but a closer and somewhat wider examination will detect the integrity of the auditory nerve and the presence of the arterial fibrosis, with the underlying predisposition of alcoholic excess, syphilis, gout, rheumatism, chronic lead-poisoning, or other constitutional state of etiologic significance.

In the treatment, the basic element is the object of attack; and whatever this may be, potassium iodide will find an indication in the arterial change, which if recognized in its incipiency can practically be controlled, providing the patient is manageable. It is the sheet-anchor, and from its exhibition in moderate doses of from thirty to ninety grains a

[2] Traité des Maladies du Cœur et des Vaisseaux.

day for a number of months, much benefit and often a substantial cure can be expected.

I am led to emphasize the importance of this vertigo becaue it is a very early symptom of a condition that, neglected, leads to distressing and even fatal results, and which unrecognized is the source of endless anxiety and misery to the patient and of chagrin and disappointment to his medical attendant. If it were desirable, numerous case-records could be cited, but it is hoped that attention once having been called to a proper interpretation of the symptom it may be less frequently mistaken, and I would urge that the condition of the arteries and the heart be made an object of early and thorough investigation in every instance in which obscure vertiginous attacks, or a persistent giddiness, is present.

THE FUNCTION OF THE LACHRYMAL PUNCTA.

BY GEORGE M. GOULD, A.M., M.D.,
OPHTHALMOLOGIST TO THE PHILADELPHIA HOSPITAL.

IN no book on physiology or on the eye have I seen any attempt at an explanation of the function of the puncta; nor have I ever been able to learn from the many ophthalmologists I have questioned that the thought of attributing to them any function whatever had occurred to them. The very name, punctum, shows ignorance of its function, since, far more than a black dot or point, it is a sphincter-guarded mouth, a lachrymos, if a word might be coined. The routine practice of ophthalmic surgeons, of "slitting up the canaliculus," in cases of epiphora and dacryocystitis, confirms the general thoughtlessness as to the utility of the punctum.

Nothing, however, is more certain than that no physical organ comes into existence except in obedience to a stringent necessity; nor does it continue in active function except it subserve a useful end. It should not therefore be destroyed except from imperative necessity. I have elsewhere[1] noted the reckless and stupid haste with which the function of the punctum is forever destroyed by the customary treatment of epiphora, lachrymal conjunctivitis, dacryocystitis, etc.

It has been long known that the punctum is surrounded by a series of muscular fibers that have precisely the action of a sphincter. This may be demonstrated by inserting a bristle or fine probe into the orifice, when the force with which the foreign body is grasped may be distinctly felt. Dust-particles pass *below* the punctum, their gravity aiding to keep them away from the opening of the punctum. The lower punctum being at the very upper border, drains off only the upper and purer part of the little lake of tears, the action of the lids and of the excess of tears washing the foreign bodies easily past the punctum to the inner canthus.

In eyes that are inflamed, the concrete exudate, both in waking and after sleep, is gathered at the inner canthus, having passed by the punctum. The same fact is observed when black dust in the eyes has been excreted by the action of tears and the lids: it is found gathered in a little ball at the extreme inner angle of the lids. By its exquisite mechanism the eye has most dextrously rid itself of the rubbish; and in doing so this has not been dumped into the capillary tubes of the canaliculus or duct. Had this, through a large patulous opening, taken place, the foreign bodies, however tiny, either mechanically by gathering and thus clogging the tiny canal, or by the reaction of the resultant irritation or inflammation, would often have closed the excretory passage-way, producing the well-known symptoms of lachrymal retention, etc.

It would therefore appear that the sensitive sphincter and punctum constitute a willing gateway for the excretion of pure tears, but a careful guard or sifter-out of dust, irritating particles, and such viscid products of inflammation as would in any way produce stenosis of the connecting drainage-system lying beyond and below. The fact would argue for the theory I have advocated[1] as regards the non-action of antiseptics upon the gonococcus in the canaliculus, sac, etc. Not only is pus a foreign body, but probably the irritation of the brush employed in making applications, etc., acts as an excitant to punctum-contraction. It would also and especially emphasize the value of other methods than those of entire destruction of the sphincter punctum, in the treatment of functional or temporary lachrymal obstruction. In these days, morever, of manufacturing and urban life, with an atmosphere increasingly thick with dust, it behooves us to pay particular attention to the preservation of a structure and function so beautifully purposive and so effectively useful to the eye.

CLINICAL MEMORANDUM.

A CASE OF HEREDITARY SYPHILIS.

BY S. M. HASLEA, M.D.,
OF ALBUQUERQUE, N. M.

FOUR years ago Mr. D., a lawyer, died in an Eastern asylum from tertiary syphilis, cerebral symptoms having been especially prominent. For several years previously to his death he had presented symptoms of insanity. Twenty-one years ago he married, his wife, then a young woman, being in the bloom of youth and in full health. At the time of his marriage the man was suf-

[1] "A Method of Infection, Treatment, and Prophylaxis of Purulent Ophthalmia," THE MEDICAL NEWS, June 11, 1892.

fering from what I suppose was the primary stage of secondary syphilis. Soon afterward his wife conceived and aborted at three months, having acquired syphilis from the fetus infected by the father. Later, another child (girl) was born at full term. This child, at the age of twelve years, showed marked symptoms of secondary syphilis, growing worse until the age of fourteen. Five years ago she came under my professional care for general treatment, but at the expiration of six months circumstances caused her to be lost to observation. Two years afterward—that is, three years ago—she returned, perfectly blind in both eyes. Only light-perception remained. Both eyes appeared perfectly opaque, of a milky whiteness. After two years of constant constitutional treatment with mercuric iodide in tonic doses, one-sixth of a grain, with hot-water baths three times a week, she seemed to recover fully from all manifestations of disease; the eyes cleared up perfectly. The girl then passed from under my professional care, apparently healthy in every respect, with not a vestige of syphilitic trouble. At the outset, believing the eye-trouble to have been caused by constitutional syphilis, nothing was done for the eyes in the way of local treatment.

MEDICAL PROGRESS.

The Saliva in Disease.—JAWEIN (*Wiener medizin. Presse*, 1892, Nos. 15 and 16) has made a study of the saliva in various conditions of disease. He found that the quantity is increased in slight febrile affections, while the fermentative activity remains unchanged, the absolute amount of ferment produced being diminished. In severe febrile affections the quantity of saliva is considerably diminished, but the amylolytic activity is increased. The diminution in quantity is greater than the increase in activity, so that there is an absolute diminution in activity. In more severe febrile affections, a minimum quantity of saliva is secreted, the amylolytic activity being likewise diminished, the reduction in both being in direct ratio to the severity of the disease. After a crisis, the quantity and the fermentative activity of the saliva fall below normal. In acute febrile diseases of protracted duration, the quantity of saliva is not rarely normal, the amylolytic activity, however, being subnormal. In even severe cases of pulmonary tuberculosis, neither the quantity of saliva nor its fermentative activity is diminished. A few days before death, the quantity undergoes change, the activity remaining unaltered. In chronic nephritis, the quantity of saliva is diminished, and its amylolytic activity is not rarely below normal, with an attendant diminution in production of ferment. In ascites, the production of ferment is greatly diminished; especially is the quantity of saliva diminished; while the fermentative activity undergoes but little change. In protracted, debilitating affections, such as scorbutus, diabetes, Addison's disease, the production of the salivary ferment is not uncommonly diminished.

The Clinical Examination of Breast-milk.—At the recent meeting of the American Pediatric Society, HOLT detailed a simple method of examining breast-milk for clinical purposes. There are two ingredients in milk that are nearly constant in their proportions: milk-sugar and the inorganic salts. Two others vary widely: fat and the proteids. From a knowledge of the specific gravity and the amount of fat, it thus becomes possible to form an approximate idea respecting the proteids. There was found to be in breast-milk a pretty constant relation between the amount of cream rising upon a given specimen in twenty-four hours and the amount of fat. The ratio was approximately two to one.

An apparatus was shown for taking the specific gravity of a small quantity of milk, and cylindrical tubes graduated in one hundred parts, from which the amount of cream could be read off at the end of twenty-four hours. The clinical significance of these data was shown by the following table, drawn from observations upon upward of three hundred specimens of breast-milk from eighty different women.

Attention was called to the fact that an estimate of the quantity must be made by other means. The specimen for examination should be taken from the middle of the nursing.

HUMAN MILK.

	Specific gravity 70° F.	Cream—24 hrs.	Proteids.
Normal average	1.031	8 per cent.	Normal.
Healthy variations	1.028–1.029	9 per ct. to 12 per ct.	Normal (rich milk).
" "	1.032–1.033	5 per ct. to 6 per ct.	Normal (fair milk).
Unhealthy "	Below 1.028	High (above 10 per ct.)	Normal or slightly below.
" "	" "	Normal (5 per ct. to 10 per ct.)	Low.
" "	" "	Low (below 5 per ct.)	Very low (very poor milk.)
" "	Above 1.033	High	Very high (very rich milk).
" "	" "	Normal	High.
" "	" "	Low	Normal (or nearly so).

The Origin and Seat of Epileptic Disturbance.—As the result of painstaking and long-continued observations and of ingenious deduction, HORSLEY (*British Medical Journal*, No. 1631, p. 693) concludes that, whatever the part first attacked by the epileptogenous agency, the principal seat of disturbance in a general or idiopathic fit is the cerebral hemispheres, and especially their cortical layer. The condition of the cortex during the paroxysm is one of congestion and not of anemia. In all probability the cerebral cortex is actually the point of origin of the disturbance.

Paralysis Agitans in a Young Man.—QUINTARD (*Bull. de la Soc. de Méd. d'Angers*) has reported the case of a youth, sixteen years old, who presented the symptoms of paralysis agitans. Two years previously, following exposure to cold, tremor appeared in the right hand and continued for a month; while within two months the tremor had reappeared, now extending to the arm and shoulder. Soon the characteristic movements also involved the lower extremity upon the same side.—*Journ. de Méd. et de Chir. Prat.*, 1892, lxiii, 5, p. 182.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will upon publication be liberally paid for, or 250 reprints will be furnished instead of payment. When necessary to elucidate the text, illustrations will be provided without cost to the author.

OVARIAN GESTATION.

OVARIAN gestation is a term that is accepted without question. It is applied, however, to a condition that has but a shadowy basis of fact. In the *University Medical Magazine* of March, 1892, there appears an abstract entitled "Ovarian Pregnancy," made from the report of a case by MACKENRODT to the Obstetrical and Gynecological Society of Berlin. The specimen, consisting of tube and ovary, is described as follows: "The tube extends in the normal condition a distance of two and a half centimeters from the uterus, then swells abruptly to the diameter of two thumbs, and regains its normal thickness at the fimbriated extremity. The latter is lost in a tumor the size of a goose-egg. The ovarian tumor is composed of a cyst, the walls of which contain ovarian tissue. The cavity of this cyst is in communication with the lumen of the tube, and is lined by a smooth amniotic layer, and contains chorionic villi."

This is the characteristic description of an ovarian gestation-cyst, based upon the supposed preformed connection between the tube and ovary. For those who can accept the possibility of such a condition the fact of a direct communication between the tube and the cyst, the expanded fimbriæ lining the opening of communication, is enough to account for the impregnation of the ovule in the distended follicle, in which the cyst originates. This would be satisfactory if it could be proved that such a connection between the tube and a follicle exists. Such a plausible hypothesis, however, is not ventured by the more competent observers. WINCKEL, for instance, accounts for the existence of ovarian gestation by the penetration of the wall of the follicle (through a rent) by the spermatozoa, and the impregnation of the ovule within the cavity. An ovarian tumor is thus formed, in which the fetus is included and surrounded by ovarian tissue, the placenta becoming attached to the wall of the follicle, the membrana granulosa being transformed into the decidua, and the ovarian stroma taking the place of the uterine wall.

The most reasonable explanation of the condition, however, is that advanced by SUTTON, in his work on *Surgical Diseases of the Ovaries and Fallopian Tubes*. He does not admit the occurrence of true ovarian gestation, basing his arguments on the following facts:

In the guinea-pig, in the mare, and in the mouse, the ovary rests in a fold of the broad ligament that partly invests the organ. In these mammals this "ovarian sac" is deeper than in the human female; its existence, however, in a developed state in women is proved by the occurrence of ovarian hydrocele, specimens of which are preserved in various museums, one in St. Bartholomew's Hospital being depicted in the work referred to (page 120). The peculiarities of ovarian hydrocele may be summarized thus: "1. The Fallopian tube opens by its abdominal ostium into a sac on the posterior aspect of the broad ligament. 2. The tube is elongated, dilated, and tortuous; the general outline of the parts resembles a retort with a convoluted delivery-tube. 3. In small cysts the ovary will be found projecting on the floor of the sac. In larger specimens it will be incorporated with the wall of the sac, and in very large specimens is unrecognizable."

In the light of these facts we may conclude that in so-called ovarian gestation it is probable that the ostium of the tube opens into an ovarian sac that has become shut in by adhesions or in some other way, the condition being possibly due to a congenital malformation.

The ovule may be discharged into this cavity and become impregnated therein, the fetus developing in the cyst thus formed. SUTTON says, further: "For a long time I made many systematic observa-

tions of the mammals in which this sac is well developed, with the notion that an impregnated ovum might be found in it, for, as far as my investigations have extended into the subject, I am convinced that ovarian gestation has no existence, but that it may have been mistaken for gestation in an ovarian sac, which, of course, is a very different matter." The specimen described by MACKENRODT coincides with the conditions present in ectopic gestation in an ovarian sac, especially as the ovarian tissue found in the cyst wall was confined to a localized area.

INFORMATION WANTED AS TO KEELEYIZED PATIENTS.

WILL asylum-superintendents and physicians generally send to the editor of THE MEDICAL NEWS any exact information that they may have as to cases of relapse to drinking-habits, of insanity, suicide, death, etc., of patients that have passed through the so-called cure of the Keeley Institutes? Correspondents will please give the names of patients, and as exact data as possible. No public use will be made of individual names, either of patients or of physicians (without consent), but in order to render the statistics useful we ask for the most accurate information possible.

THE PITTSBURG MEDICAL REVIEW AND THE ASSOCIATION JOURNAL.

IN congratulating the members of the medical profession of the State of Pennsylvania upon their success in securing the passage of the resolution requiring the purification of the *Journal of the American Medical Association* from the nostrum stain, we are glad to mention the good work done by the *Pittsburg Medical Review*, which has been and is vigorous, earnest, and outspoken for the right.

SOCIETY PROCEEDINGS.

AMERICAN MEDICAL ASSOCIATION.

Forty-third Annual Session, held at Detroit, June 7, 8, 9, and 10, 1892.

(Continued from page 711.)

SECTION ON NEUROLOGY AND MEDICAL JURISPRUDENCE.

FIRST DAY—JUNE 7TH.

The Chairman, DR. HAROLD N. MOYER, of Chicago, made a few remarks concerning the origin and growth of the Section on Neurology and Medical Jurisprudence

MR. HENRY A. CHANEY, of Detroit, read a paper entitled "Responsibility in Will-making."

Reference was made to the earlier interpretations in common law, that inasmuch as mind is one and indivisible, no one faculty could be deranged without invalidating the mind as a whole. Later decisions were more and more lenient, and now there is less and less disposition to interfere with wills made in states of unsoundness. Cases of insanity were reported in which wills had been sustained, notwithstanding the existence of mental unsoundness; others in which they were not sustained. The necessity for more light in will-cases in which a belief in spiritualism is alleged as evidence of incapacity, was pointed out. A plea was made for the determination of some definite degree of dementia to mark the limit of testamentary capacity.

DR. C. G. COMEGYS, of Cincinnati, read a paper entitled "A Healthy Brain is Necessary to a Free Will." He emphasized the dependence of healthy mental action upon the existence of a healthy state of the brain; and the faculty of will, as the governing power, was given the place of preëminence in the mental life. A plea was made for mental hygiene as the means of overcoming many of the vicious tendencies of modern life.

DR. C. H. HUGHES, of St. Louis, followed with a paper entitled "Hysterical Concomitants of Organic Nervous Disease." He pointed out the early prominence of hysterical symptoms in many cases of organic nervous disease, and emphasized the necessity for a due consideration of this fact in diagnosis. Hysterical symptoms are not so much symptoms of the organic malady as signs of a neurosis, to awaken which into activity the organic disease sufficed.

DR. C. K. MILLS, of Philadelphia, then read a paper on "The Pantomimic Disorders of Aphasia," citing numerous cases to show that, along with speech-defects, there were often related defects of pantomime, and these defects were classified after the same manner as those of speech.

DR. C. G. CHADDOCK, of Traverse City, Mich., read a paper entitled "Retinal Excitation of Cortical Origin in Visual Hallucination," in which he attempted to show that the prevailing assumption of a severe "current" from center to periphery in hallucination is unnecessary; and that the element of objectivity in visual hallucination may be as rationally assumed to be afforded by indeterminate stimuli coming from periphery to center.

SECOND DAY—JUNE 8TH.

Morning Session.

DR. A. D. ROCKWELL, of New York, read a paper on "Executions by Electricity." He stated that while not altogether in favor of capital punishment, yet he was firmly of the opinion that if the law must destroy, it should do so decently. As one of the Commission appointed by the State of New York to determine the best method of procedure in carrying out the Act for electric executions, he had found that a strength of 1000 volts was the maximum of current required to instantly destroy any animal, large or small. The recent executions, however, demonstrated that a stronger current was required to extinguish life in a human being than in any domestic animal, however large.

He ascribed this fact to causes both physical and psychic. Because of the fright experienced by the criminal about to undergo the death-penalty, the blood leaves the periphery, thus causing the body to oppose a greatly increased resistance to the passage of the current. In the second place, the victim knows what is coming, and every nerve and muscle is tense with involuntary resistance. In animals these conditions do not prevail, and in accidental killings by electricity it had many times been demonstrated that instant devitalization had taken place by contact with electric potentials less than those employed in judicial executions. When a current of lethal energy (from 1500 to 2000 volts) is employed, it is mathematically impossible that pain should be experienced.

No one that has once witnessed a properly conducted execution by electricity will fail to commend it as a most humane method, as compared with hanging.

Aside from the fact that a human life is being taken, there is little in connection with the execution that is revolting to the senses. After the first convulsive movement, as the current is received, every muscle is simply tense and motionless until the current is broken, when relaxation takes place, and the victim is to all intents dead. The scorching and blistering, about which so much has been said, are superficial, and so slight as to be unworthy of comment.

Dr. Rockwell was of the opinion that a question that could and would be determined related to the possibility of making the current act exclusively on the centers of life and nervous activity, so that they would be instantly devitalized, and at the same time leave no outward manifestation of the terrific power employed.

DR. GEORGE E. FELL, of Buffalo, N. Y., presented a paper entitled "Electrodes and their Application in Electrocution." He stated that he was the first to make demonstrations upon the lower animals directly in connection with this subject. From his investigations he strongly endorses electrocution as the most humane, as the readiest, least troublesome, and least horrible method of inflicting the death-penalty, from the standpoint of suffering on the part of the criminal, and also from the effect upon the officers who must carry out the law. Dr. Fell objects to the application of the electrode to the feet, the thigh, or the forehead, for the reasons that the vital portions of the body are not so positively affected in those locations as they would be in others. In applications to the feet or to the thigh there is an undue amount of resistance obtained through the extent of tissue that the current must traverse. He thinks that for many reasons it were better to apply one electrode to the top of the head, so as more directly to influence the cerebrum and spinal cord, and one to the epigastric region, as close to the apex of the heart as possible, so that the full force of the current would be expended upon the nerve-centers in the brain, spinal cord, and upon the muscular tissue of the heart. His argument is based upon experiments made upon the lower animals, which prove conclusively that the nearer the electrode is placed to the heart, the more suddenly this organ ceases action. He claims that this location of the electrode could be more easily made than that to the thigh; that it would be more positive in result, and could be applied before the culprit left the cell—the connection with the dynamo wires and the saturating fountain syringes being easily and quickly made after the culprit sits in the chair.

Afternoon Session.

DR. W. H. HOWELL, of Ann Arbor, Mich., read a paper entitled "Nerve-regeneration After Suture," in which he gave an account of a research undertaken in connection with Dr. G. C. Huber, upon the general subject of nerve-degeneration and regeneration, which has been awarded the prize of the American Physiological Society. Four main points were taken up for investigation, namely, the possibility of immediate union in a severed nerve without degeneration of the distal extremity; the possibility of union with return of function between the central portion of any one spinal nerve and the distal portion of any other; the histologic changes in the distal extremity of the nerve during degeneration and regeneration; a tabulation and critical *résumé* of the surgical cases of primary and secondary sutures, with especial reference to the evidence from this source as to immediate union.

In the experiments dogs were used. The ulnar nerve was chosen for the operations, which were performed as aseptically as possible. In some cases the nerve was cut and sutured with catgut; in others it was crushed; and in others still it was coagulated over a narrow area by a stream of hot water. Some fifty-eight experiments were performed—the chief results of which are as follows:

However the continuity of the nerve was interrupted, whether by section, with subsequent suture, by crushing or by coagulation, immediate reunion without degeneration of the distal extremity could not be obtained in any case. In every instance the distal extremity underwent complete degeneration, which was studied histologically. When sufficient time was allowed, and the distal extremity remained in connection with the proximal extremity, regeneration ensued. The first return of function in the nerve operated upon (the ulnar, at the elbow) was detected at about the end of the third week (twenty-one days) after the operation. With reference to the possibility of the distal extremity of one nerve uniting with the central extremity of another, with return of function, the nerves operated upon were the ulnar and median. The operation was perfectly successful; after a certain interval, sufficiently long for the processes of degeneration and regeneration to have taken place, the distal piece when laid bare and stimulated directly was found to have recovered its irritability perfectly.

In all of the operations the nerves were preserved and studied histologically, both in sections and in teased preparations. The paper gave a complete description of the progressive changes of degeneration from the beginning of the segmentation of the myelin and axis up to their complete absorption. In regeneration, which starts early in the stage of degeneration, the nuclei of the sheath at first take the most prominent part; they proliferate, migrate, and eventually form a continuous band or fiber of homogeneous protoplasmic material, the "embryonic fiber." The active growth of this embryonic fiber brings it in connection with the old fibers of the central extremity, through the intervening cicatricial tissue. After this connection is established the myelin

arises as isolated drops in the protoplasm of the embryonic fibers by a process of chemical differentiation. The drops afterward unite to form a continuous tube of myelin, and into this the axis of a fiber of the central extremity grows down.

The review of surgical literature corroborates the results of experimental work in showing that immediate union without degeneration is impossible, but that under proper conditions union between the two severed extremities will take place, and be followed by regeneration of the peripheral extremity.

DR. SANGER BROWN, of Chicago, read a paper entitled "Hints Upon the Pathology of So-called Friedreich's Disease, Based Upon the Study of a Series of Twenty-three Cases," in which he pointed out that there has been such a large accumulation of recorded facts that the conclusions previously reached are no longer tenable. Two broad divisions may be made: in one heredity can be demonstrated to play a prominent part; in the other this influence is not apparent. Of the former, the so-called Friedreich's disease may be taken as a type, and of the latter the ordinary form of tabes; and unless it should be demonstrated that heredity plays an important part in the progressive form of spinal muscular atrophy, and in disseminated sclerosis, the pathologic process giving rise to the symptom-complex, commonly described as Friedreich's disease, must, at the present time, be regarded as constituting the sole instance of hereditary degenerative disease of the central nervous system. In this disease, the essential pathologic features are that certain tissues have derived such a deficient vital endowment from the parent that they undergo a more or less premature, rapid, and extensive degeneration; further, the effect of this process is mainly, if not exclusively, confined to the so-called upper nerve-segment and to the conducting filamentary process, and does not involve the body of the cell of this segment.

Dr. G. FRANK LYDSTON, of Chicago, followed with a paper entitled "Reflex Genito-urinary Neuroses." He stated that there is, perhaps, no subject in the whole range of genito-urinary disturbances of greater importance than the varied phenomena involving nervous derangements that are due, directly or indirectly, to pathologic conditions of the various portions of the urethral canal.

When it is considered what a vast amount of labor and talent has been devoted to the study of the reflex neuroses of the female, due wholly or in part to pathologic conditions of the uterus and its appendages, it is surprising that more attention has not been given to analogous conditions in the male, due to disturbances of the generative organs and especially of the urethra.

Quite a close similarity exists between some of the morbid conditions of the prostate gland and those affecting the uterus. Physiologically, the prostate, or at least a portion of it, is the homologue of the uterus, there being the closest resemblance in the muscular structure of the two bodies. If the muscular tissue becomes perverted in growth, we have in the one uterine myoma, and in the other prostatic hypertrophy, the structure of the two morbid processes being strikingly similar. When, as is occasionally the case, the "third lobe" of the prostate becomes so enlarged as to form a distinct tumor, it is generally not unlike a pedunculated fibroid. It will also be found that certain remedies that have a pronounced action upon unstriated muscular fiber have a somewhat similar action upon the prostate and uterus, this being especially true of secale, ustilago maidis, and hamamelis. Certain sedative remedies act very similarly upon irritative affections of the uterus or ovaries, and upon those of the prostate. It will further be found that certain irritations affecting the prostate will produce effects quite like those produced by utero-ovarian irritation in women. False spermatorrhea (spermatophobia), pseudo-impotence, attended with disgust for the sexual act, melancholia, hypochondria, neuralgias, whether of the contiguous or of remote nervous filaments, and nervous inhibition amounting to almost complete paresis, are all possible results of urethral or prostatic irritation. These conditions are all represented by similar disturbances, such as hysteria and allied affections in the female, due to morbid conditions of the generative organs. The analogy between the results of prostatic catarrh and those of cervical catarrh is sometimes especially striking.

DR. L. BREMER, of St. Louis, read a paper entitled "The Reflex Theory of Nervous Disease." He stated that a peculiar antagonism exists among the representatives or followers of the several special branches. The chief interest of their reports generally centers in the observation that by successfully treating a disease of the organs to which *they* pay special attention, symptoms in distant organs that other specialists claim as their domain, have vanished, the additional remark being generally made, that the patient had been treated by a specialist of another order without any benefit. Dr. Bremer stated that the irritable bladder, the irritable urethra, prostate, rectum, or perineum, with distant associated nerve-complication—affections that do not call for operative interference any more than does the irritable breast or the irritable heart, have all more or less unnecessarily been tampered with from ignorance of the fundamental teachings of neurology. Cases of functional, central, and coarse systemic nerve-disease are locally treated as vesical or rectal affections.

Another phase in the evolution of theory and application of the law of reflex action, illustrative of the blending of reality and imagination, of truth and fiction, is the relation of ocular defects with certain neuroses. Since it has become known that visual abnormalities often accompany nervous diseases, oculists have tried to establish a causal connection between eye-affections and neuroses, just as gynecologists, aurists, rhinologists, dentists, etc., have done. The reflex theory here affords a new field for application. Dr. Bremer criticised the harmful and noxious feature of specialism, tending by its luxuriant growth to overshadow, obscure, and dwarf internal medicine, so-called—*i. e.*, that science which alone is capable of rendering the specialist fit for his work, and insuring that success which is not gauged by the amount of money he makes, but by the real and substantial aid that he bestows upon his fellow-men.

THIRD DAY—JUNE 9TH.

Morning Session.

DR. J. G. KIERNAN, of Chicago, read a paper entitled "Premature Paretic Dementia and its Forensic

Relations," in which he stated that many European and some American alienists had drawn the line between insanity attacking an intact organization and that attacking one already disordered by heredity or disease. What is true of insanity is also true of paretic dementia. The organization attacked may already be the victim of a constitutional disease like pulmonary tuberculosis, in which case the emotional exaltation of the *spes phthisica* becomes exaggerated with the emotional state of true paretic dementia, permeated, however, by a suspicional phase. The claim has been made that these are not cases of paretic dementia plus the individual defect, but new types of paretic dementia. Fournier, for example, went so far as to claim that syphilis produced a pseudo-paretic dementia. Dr. Kiernan has already shown that there are exceedingly valid grounds for refusing to admit the existence of such a type.

Regis has gone even further than Fournier, for he claims that "beside the type of paretic dementia which becomes developed in its own time, and which is the true paretic demetia, there are other cases which occur unexpectedly some time before, others after the ordinary period, which may be said to range between the ages of twenty-five and sixty-five years. The first may be designated as premature paretic dementia, the second as late paretic dementia. Cases before the age of twenty-five years are very rare, and only a few cases are recorded in which the onset occurred before the age of twenty. The premature type, unlike the ordinary type, has always a powerful etiological factor, such as heredity, syphilis, traumatism, saturnism, or general or local diathesis. These causes appear to determine in suitable cases an early predisposition and to prematurely place the brain in those conditions in which it is found in mature life. Premature paretic dementia has a slower progress and a longer duration; it is more frequently subject to remissions and is susceptible of a more or less permanent cure." To the designation premature, and to the positiveness of the position here taken, Dr. Kiernan has shown that most decided objections exist. The symptoms that Regis has grouped under this title may appear at any age, and are due to the organism attacked. Whatever be the etiologic factor, the organism attacked tinges the paretic dementia and not the etiologic factor. The normal organism furnishes the typical paretic dementia; the organisms in which a neurosis has been set up by pulmonary tuberculosis, syphilis, gout, rheumatism, traumatism, lead-poisoning, insolation, heredity, ataxia, or other causes, furnish atypical cases of paretic dementia presenting many features in common.

A prominent clinical feature is the temperature. Rottenbiller has found that in paretics the temperature is subnormal, and that extraordinary variations, without apparent cause, are frequent. In one case the temperature rose from 97° F. in the morning to 102.6° F. in the evening, falling again to 88° F. on the next morning. These characteristics are present in the early stages of the disease and in remissions. In these, the asymmetrical axillary temperature, to which attention was called about a decade and a half ago, is peculiarly frequent.

DR. THOMAS H. MANLEY, of New York city, followed with a paper entitled "The Relation of Special Violence to Hernial Protrusions through the Abdominal Walls."

He endeavored to demonstrate that the evolution of abdominal hernia of any type is never solely dependent on traumatic influences.

Taking the ground that the predisposing cause of hernia is always congenital, Dr. Manley maintains that concussive force can never be regarded in any other light than as an incidental event, which may aggravate the condition of an already existing hernia or provoke the full descent of another that has not yet left the cavity of the peritoneum. In all of the numerous post-mortem examinations that he has made, in cases of crushing injuries of the body, in which the solid or hollow viscera of the abdomen have been lacerated or rent, he has never discovered evidences of a recent abdominal protrusion. Hernial disease of the inguinal or crural variety is as common in the unmarried or non-childbearing as it is in those who have gone through the throes of labor and thereby subjected the organs to the violent expulsive efforts of parturition.

While the foregoing applies to violence as a cause of hernia, it must not be forgotten that local injuries, in varying degree, directly applied immediately over an already existing hernia, may be followed by serious consequences; although this must be very rarely the cause.

Dr. Manley related cases that have come under his own observation, in which it was alleged that the hernia had succeeded to injuries, but in which it was demonstrated incontestably that the patients had all had hernia before.

DR. T. D. CROTHERS, of Hartford, Ct., read a paper on "The Law of Periodicity in Inebriety." He contended that the periodicity of the drink-paroxysm is unquestioned evidence pointing to central brain-disease.

Heredity, nutrition, mental exhaustion, and environment, are all common causes or predisposing factors of this disease. Allied diseases, of which epilepsy is common, are associated, and are interchangeable with this and similar affections. The drink-periodicity follows a uniform line of events, ending in about the same way in nearly all cases. Its varieties and symptomatology are practically the same in the regularity of origin, development, and termination. These cases are the most certain and dangerous of all drink-neurotics, and are the least understood. The prognosis is uncertain, and full of dangerous possibilities; the natural tendency is to death. These cases are, however, quite amenable to treatment, if the measures are applied scientifically, and with full knowledge of the causes. Their insanity is more positive than that of other inebriates, but the drink-impulse is often controllable, and frequently disappears with treatment. This class requires the most careful medication and study.

Medico-legally, the most important problems are associated with these drink-paroxysms. Each case requires special study, and is to be judged by the general principles of physiology and psychology.

Such cases of necessity have impaired control of brain and nerve, and cannot be measured by the rules or standards of mental health. These cases should receive careful study and examination.

Tabulated facts, of sufficient number and accuracy, are needed from which to draw accurate conclusions, covering the laws that govern this class of neurotics. When the causes are known, their curability is assured by the application of means known to science.

DR. RICHARD DEWEY, of Kankakee, Ill., read a paper entitled "Insanity Following the Keeley Treatment for Inebriety." He stated that, as Superintendent of the State Insane Hospital at Kankakee, there had come under his observation eight patients committed directly after a residence at Dwight. In the first case, insanity had never occurred until after the Dwight treatment and a cure was effected. In the second case of morphine-habit, insanity developed after the Keeley "home-treatment." The insanity failed to yield to treatment. The third case was one of the alcohol-habit, sent to the Kankakee Insane Asylum after treatment at Dwight. The patient was cured of insanity, but he continued to drink. Case four, addicted to the alcohol, morphine and cocaine habits, was treated at Dwight, relapsed, became wildly insane, recovered mentally, but still drinks. Case five, addicted to the alcohol and morphine habits, was sent to the insane asylum from Dwight, and is still in the asylum. Case six, addicted to the alcohol, morphine and cocaine habits, took the Keeley "home-treatment," and was sent to Kankakee Insane Asylum. He was not insane before going to Dwight, but was received at Kankakee insane and was discharged cured. Case seven, an alcohol case in which insanity developed at Dwight, while under treatment, is still in the insane asylum. Case eight, an alcohol case, in which insanity developed one month after leaving Dwight, was not previously insane, and is still in the insane asylum.

In each of these cases insanity and melancholia directly resulted from the Dwight treatment. There seems to be no doubt that ordinary well-known tonics are combined with some narcotic or mydriatic drug, probably atropine. As to the presence of gold there is great doubt. Moral influences are remarkable; the patients go to Dwight with an earnest expectation of benefit, and are thus placed in the most favorable attitude for beneficial results. Keeley claims 95 per cent, of cures, while the figures of the bichloride of gold clubs are even higher, but both neglect to state what constitutes a cure. Does a cure mean one or five years' of abstinence? And do the figures given embrace all of the cases treated or only those about whom information is forthcoming?

In the first place, drunkenness is not like rheumatism, paralysis, tuberculosis and bodily diseases, whose presence or absence can be demonstrated. The cure of drunkenness is a more difficult matter to ascertain. No one can follow up all of Keeley's patients for months and years to see how they turn out. Patients may be still drinking in the outside world, and deny it, or deceive others. There are many whose paroxysms of drinking are separated by months or even years; and there must be hundreds who drop out of sight, especially if they relapse.

Dr. EUGENE S. TALBOT, of Chicago, followed with a paper entitled "Evidence of the Somatic Origin of Inebriety." He stated that Dr. Langdon Down first called the attention of the profession to the fact that contracted arches and high vaults were common among idiots. There is a larger percentage of deformities among inebriates than among any other defective class. These deformities, however, are not so pronounced as those found among idiots and the criminal classes. The large percentage of deformities and high vaults indicates a strong neurotic tendency early in life, even before the seventh year. Finally, if a child between seven and twelve years of age has arrested development of the superior maxilla, and possesses constitutional irregularities of the teeth and high vault, it can almost invariably be concluded that it will become, not always an idiot, but perhaps a genius in some one direction, or an idiot, or deaf, dumb, blind, insane, criminal, an extreme egotist, excessive tobacco-user, or an inebriate, all of these conditions coming under the head of degenerates, or neurotics. In making a diagnosis of any one of these classes of individuals, the following three conditions of deformities of the jaws should always be taken into account, viz: arrest of development of the superior maxilla, constitutional irregularities of the teeth, and high vaults.

DR. WILLIAM FULLER, of Grand Rapids, Mich., read a paper on "Cerebral Anatomy," which he illustrated by casts.

DR. THOMAS L. WRIGHT, of Bellefontaine, O., presented a paper entitled "Some Characteristics of the Human Mind When It is Placed at a Disadvantage." He stated that without any failure in itself the mind of man may be imposed upon by uncommon and so-called "false" presentations of external nature through the senses. It may also be the victim of misrepresentations arising from certain states of the brain and senses dependent upon disease. Again, it may be constrained and deceived by the action of toxic or other foreign (and perhaps irritant) agents upon the organism, and especially upon the brain and nerves.

The sources of all this mental error and perturbation may be either subjective—from within; or they may be objective, having no relation to the environment.

The traveller in the desert may be honestly misled by *mirages* presenting various deceptive appearances.

The strange condition known as hypnotic—sometimes called mesmeric—and in olden periods esteemed to be enchantment, is an illustration of a state of mind deceived, but powerless, because powerless to choose.

The over-sensitive brain may give birth to such illusions and hallucinations as will vividly deceive the mind and fill it with morbid delusions, beliefs, and purposes.

Toxic agents likewise may produce similar sensitive and mental effects. Alcohol, especially, affecting in a toxic manner the entire organism, may through anesthesia and its many other injurious properties, produce absolute mental and physical degeneration. The intellectual and moral faculties are overwhelmed *en masse*. All is confusion, wreck, incoherence.

In these Instances of mental incompetency, there is, in strict equity, a similarity, and not infrequently an identity in the character of the responsibility for conduct.

Attempts have been made to regulate disorganization, to classify confusion, but the subject of inebriate-responsibility is a difficult one, and it is far from being satisfactorily settled.

DR. THEODORE DILLER, of Pittsburg, reported "A Case of Tumor of the Pons, in Which Tapping of the Lateral Ventricles was Done for the Relief of Intracranial Pressure."

A healthy German, fifty-seven years old, free from syphilis, fell from a gondola car in October, 1890, striking the back of his head. He did not lose consciousness.

Soon afterward, he began to have headache, difficulty and uncertainty in walking, and paresis of the left side of the face, the left arm and the left leg, with difficulty in swallowing and in talking (bulbar symptoms). There was little disturbance of sensation. There were no convulsive seizures or twitchings at any time. There was no vomiting. An advanced degree of optic neuritis was found.

When the scalp was shaved, a distinct elevation of bone, about the size of pea, was noted just to the left of the median line, and immediately over the leg-center. Although the symptoms alone seemed to indicate a bulbar lesion, yet the history of the fall and the presence of a small bony excrescence tended to throw some doubt upon this diagnosis. There was, doubtless, a good deal of intra-cranial pressure. It was determined to trephine on the right side, over the leg-center, just opposite the small bony excrescence, and tap the lateral ventricle if nothing was found at that place.

The internal table of the skull was found healthy. There was no disease of the brain. The bony exostosis appeared to be congenital. The lateral ventricle was tapped, and two or three ounces of fluid removed. A rubber drainage-tube was inserted into the ventricle, and a large amount of fluid escaped up to the time of death of the patient, thirty-six hours later.

The autopsy revealed a tumor, as large as a walnut, on the left side of the pons, pressing upon the pyramidal tracts and olivary body. The growth proved to be sarcomatous.

The following were elected officers of the section for the ensuing year:

Chairman—Charles K. Mills, Philadelphia.

Secretary—J. G. Kiernan, Chicago.

Members of the Executive Committee—O. Everts, Cincinnati, Ohio, three-year term; H. N. Moyer, Chicago. two-year term, and Justin E. Emerson, Detroit, Mich., one-year term.

SECTION OF OPHTHALMOLOGY.

Of the forty-eight papers on the program, about forty were read. The majority related to purely ophthalmologic subjects, and were chiefly of interest to the ophthalmologist. A brief reference to some of the papers of more general interest is given.

The Chairman of the Section, DR. J. L. THOMPSON, of Indianapolis, in his opening address, advocated the preparation of fewer papers for the meetings and the allotment of more time for their proper discussion. He thought that in this way the meetings of the Section would be more productive and more helpful.

DR. B. ALEX. RANDALL, of Philadelphia, read a paper entitled "A Study of the Eyes of Three Hundred and Fifty-seven Boys in the Penn Charter School, of Philadelphia, with Notes on the Examination of School Children." He referred to the importance of such studies and to some of the defects in the examinations heretofore made. To be of value, such examinations should include a study of distant vision, of astigmatism, of muscle-balance, of the punctum proximum of each eye with Jaeger No. 1, the refraction by the direct method, retinoscopy, and if necessary by lenses, and of the color-sense. To these data should be added notes in regard to general health, etc.

DR. GEORGE T. STEVENS, of New York, read a paper on "The Relation of the Motor Muscles of the Eye to Certain Facial Expressions." He stated that years of observation of anomalies of the muscles that govern the movements of the eyeball, and the fact that remarkable changes often follow modification of these muscles, had led him not only to regard with greater care these changes, but to bring to the subject the aid of photography. Photographic portraits of more than two thousand persons had been taken, the records of whose ocular conditions have been carefully and repeatedly made. The facial conditions associated with relative tension of the various muscles were described in detail and illustrated by drawings.

DR. A. J. ERWIN, of Mansfield, Ohio, read a paper on "The Treatment of Incipient Cataract." He reported several cases in which the progress of the condition had been retarded or checked by the use of galvanism and the application of tincture of iodine to the lids. While not condemning operation, he suggested that a trial of the method indicated be made in cases in which the degree of vision retained is equal to the average vision that might be expected after extraction of the cataract.

DR. EUGENE SMITH, of Detroit, read a report of a "New Operation for Trichiasis and Distichiasis." Incisions are made between the faulty and normal hairs, exposing the hair-follicles and destroying the follicles connected with the distorted hairs by means of a fine galvano-cautery. The operation has been performed fifty times with satisfactory results.

DR. GEO. FRIEBIS, of Philadelphia, reported a "Case of Congenital Ectopia Lentis" in a boy seven years of age. In the discussion of the subject several speakers referred to families in which from three to five of the members suffered from the same condition. DR. SMITH, of Detroit, mentioned a case in which the individual had the power of dislocating the lenses at will by throwing the head forward, and replacing them by reversing the movement.

DR. B. L. MILLIKEN, of Cleveland, presented a paper entitled "Injuries to the Lens, with Cases." In the treatment the first requirement is removal of the foreign body, if this is possible, followed by the use of aseptic and antiseptic washes. Atropine, in solution sufficiently strong to dilate the pupil and keep the iris out of harm's way, is of great value. The eye should be kept at rest, as the cataract that follows is doubtless largely due to abusive use of the eye. The alternate use of atropine and eserine is of service in attachment of the iris. In the old, the use of atropine must be carefully watched to avoid the development of glaucomatous symptoms. In several of the cases reported, absorption of the lens followed the formation of the cataract, and useful vision was secured.

DR. CHARLES A. OLIVER, of Philadelphia, reported a similar case.

DR. JULIAN J. CHISOLM, of Baltimore, read a paper on "The Advantages of Optico-ciliary Neurotomy over Enucleation." Neurotomy is advocated if the eye is not deformed in appearance, although it may be sightless and the source of suffering and danger. Dr. Chisolm has performed the operation many times and has never seen any unpleasant consequences. While in a few cases subsequent enucleation became necessary, in the ma-

jority, division of the nerves proved to be all that was needed.

DR. F. C. HOTZ, of Chicago, read a paper on "Thiersch's Skin Grafts in Ophthalmic Surgery," giving the results of experiments in the operation for pterygium. After the pterygium is dissected back toward the caruncle, a graft of skin taken from the forearm is applied to the open space in such a way that one edge of the graft is placed in apposition with the margin of the cornea. In three cases thus treated the result was entirely satisfactory, the graft forming a barrier to the reproduction of the pterygium.

Several cases of "Orbital and Ocular Growths" were reported by DR. J. A. WHITE, of Richmond, Va., and DR. W. M. GRAY, of Washington; by DR. EDWARD JACKSON, of Philadelphia, and by DR. GEORGE E. FROTHINGHAM, of Detroit.

In the discussion that followed, the point was brought out by DR. KNAPP and others, that many of these orbital tumors, although under the microscope presenting the typical appearances of sarcoma, are benign in character and often disappear spontaneously.

DR. H. GRADLE, of Chicago, read a paper on "The Etiological Relations of Nasal Anomalies to Diseases of the Eye," detailing the various ocular affections that might be caused by nasal troubles.

DR. CHARLES H. THOMAS, of Philadelphia, read a paper entitled "An Operation for Stricture of the Lachrymal Duct," advocating stricturotomy for the radical cure. He described a stricturotome, consisting of a combined sound and knife. He reported cases in which the operation had been performed many years ago, and in which there has been no return of the trouble.

DR. LEARTUS CONNOR, of Detroit, read a paper entitled "Heterophoria as a Cause of Rhinitis and Tinnitus Aurium," reporting the case of a young woman who, for eighteen months, had been subject to frequently recurring attacks of rhinitis associated with tinnitus aurium, and in which the trouble was completely relieved by wearing prisms for the correction of heterophoria. The withdrawal of the prisms was always promptly followed by a return of the rhinitis.

DR. SAMUEL D. RISLEY, of Philadelphia, read a paper on "Conservatism in the Treatment of Disease of the Lachrymal Passages." He stated that the canaliculus should not be slit up unless absolutely necessary. Obstruction is often due to a general thickening of the mucous membrane, rather than to a localized stricture, and the treatment should be directed to the removal of the general thickening. It was shown that the lachrymal punctum is provided with a sphincter muscle. Dilatation of the punctum and stretching of this muscle is often sufficient. Probes are sometimes required, and occasionally it may be necessary to slightly nick the punctum.

DR. G. A. ASCHMAN, of Wheeling, read a paper entitled "Closure of the Lachrymal Puncta in Dacryocystitis as a Barrier against Infection of the Wounded Eyeball." A small galvano-cautery is introduced into the canaliculus.

DR. GEORGE M. GOULD, of Philadelphia, read a paper entitled "A Method of Infection, Treatment and Prophylaxis of Purulent Ophthalmia" (THE MEDICAL NEWS, June 11, 1892, p. 657).

The Section elected the following officers for the ensuing year: *Chairman*, Dr. Samuel D. Risley, of Philadelphia; *Secretary*, Dr. H. Gradle, of Chicago.

NEWS ITEMS.

International Dermatologic Congress.—The second Dermatologic Congress will be held in Vienna from the 5th to the 10th of September, 1892.

Many of the most distinguished representatives of Dermatology and Syphilography from all countries have promised to present papers, and the indications are that, from a scientific standpoint, the meeting will be a great success.

The Committee on Organization, through the President, Prof. Kaposi, has extended a cordial invitation to the members of the American Dermatological Association and of the New York Dermatological Society and others interested in dermatology in this country to be present.

The membership fee [five dollars] should be sent with titles of papers intended for presentation to the Secretary for North America, Dr. Prince A. Morrow, 66 West Fortieth Street, New York, or to the Secretary-General of the Congress, Dr. Gustav Riehl, Wien, Bellaria Strasse, 12.

Against Proprietary Medicines.—At the meeting of the Missouri State Medical Association, Dr. L. Bremer, of St. Louis, Mo., introduced the following resolutions, which were unanimously adopted:

Whereas, The evil of prescribing and recommending proprietary medicines is constantly increasing, much to the detriment of the profession and the public, especially the latter, many of whom are led into the drug-habit; therefore,

Be it resolved, by the members of the Missouri State Medical Association, That we condemn the practice on the part of some physicians of giving certificates as to the efficacy or special uses and advantages of proprietary medicines, or what is usually understood by this term.

Resolved, That as a body we recommend to the profession the future discontinuance of such medicines, if now used by them.

Medico-Legal Society of Chicago.—At the annual meeting, held June 4, 1892, the following officers were re-elected: President, Judge Oliver H. Horton; First Vice-President, Daniel R. Brower, M.D.; Second Vice-President, James Burry, M.D.; Treasurer, Joseph Matteson, M.D.; Secretary, Archibald Church, M.D. Drs. J. Eliott Colburn and Harold N. Moyer were unanimously elected to active membership.

BOOKS AND PAMPHLETS RECEIVED.

Medical Society of Franklin County; its History, and Sketches of Early Practitioners of the County. By John Montgomery, M.D. Chambersburg: Published by the Society, 1892.

Medical Society of the State of New York; Report on Capital Punishment. Reprint, 1892.

Uses of Water in Modern Medicine. By Simon Baruch, M.D. Vol. I. Detroit, Mich: George S. Davis, 1892.

Wayside Optics: Studies in a Railway Train. By Casey A. Wood, A.M., M.D. Reprint, 1892.

INDEX.

ABORTION, habitual, asafetida for, 410
Abscess, bilateral lumbar, associated with Pott's disease, 65
cerebral, successful operation for, 352
in the region of the medulla oblongata, two cases of, 300
of the temporal lobe, successful trephining for, 132
of the temporo-sphenoidal lobe and of the middle lobe of the cerebellum, 549
of the tibia of long standing and chronic ostitis, 269
Absorbent gauze, pads of, as a substitute for flat sponges in abdominal surgery, 713
Acne, remedy for, 302
rosacea, 265
Acrania, a case of, 298
Actinomycosis, 99
Adenoid growths, removal of, from the vault of the pharynx, 379
Adenoma, papilliferous fibro-cystic, of aberrant breast nodule, 269
Advertisements, copies of, desired, 328
sneak, 496
Age, at what, may a woman marry? 182
Agraphia, hysterical mutism with, 215

Tocci brothers, of Locana, Italy, the blended, 629
Tolerance, abdominal and uterine, in pregnant women, 468
Tonsillitis, case of, tracheotomy, 550
Tonsils, faucial, removed by the galvano-cautery snare, 321
Toxic effects of impure chloroform, 301
symptoms from sulphonal, 438
Toxicity of the blood in mammifera after removal of supra-renal capsules, 437
of the serum of the blood in puerperal eclampsia, 354
of the urine in diseases of the liver, 187
Trachea, a needle in the, 216
Tracheotomy for obstruction of the pharynx, with removal of mucous polypus from the nose, 72
in a case of tonsillitis, 590
Trade-mark, the value of, 586
Transmissibility of carcinoma, 354
Transmission of tuberculosis by the seminal fluid, 354
Transperitoneal nephrectomy, 493
Traumatic rupture of the intestine successfully treated by laparotomy, 20
Traumatism, extensive trephining for the relief of epilepsy from, 548
three cases of neurotic edema following, 432
Trephining, extensive, for the relief of epilepsy from traumatism, 548
successful, for abscess of the temporal lobe, 132
for basal hemorrhage, 132
Triceps, division of tendon of the, for reduction of complete outward dislocation of the radius and ulna at the elbow, 549
Tubercle-bacilli, pure culture of, from sputum. 658
attenuation of, 353
Tuberculin, an immunity-conferring principle in the blood of animals treated with, 301
and tuberculocidin, combined employment of, 464
as a diagnostic agent in cases of tuberculosis in cattle, 358
in the diagnosis of tuberculosis in cattle, the value of, 415
in the treatment of leprosy, 244
Tuberculin, should it be administered in private practice? 340
the blood during treatment with, 580
the utility of, in experimental tuberculosis of the eye in rabbits, 20
Tuberculocidin, a remedy for tuberculosis, 441
and tuberculin, conjoined employment of, 494
Tuberculosis, pulmonary, camphoric acid for the night-sweats of, 293
congenital, 76
glandular, differentiation of pseudo-leukemia and, 437
in cattle, the value of tuberculin in the diagnosis of, 415
tuberculin as a diagnostic agent in, 358
in the city of Philadelphia, the influence of the doctrine of contagion upon the death-rate from, 539
in the goat, 188
of pericardium, 271
of the kidney, para-peritoneal nephrectomy for, 436
of the larynx, insufflation for, 580
pseudo, 132
pulmonary, potassium cantharidinate in the treatment of, 159
the curability of, 190
the cure of, 272
what relationship has chronic nephritis to, 421
pulmonum, phthisis and, 20
the curability of, 190
the use of gold and manganese in, 128
transmission of, by the seminal fluid, 354
treatment of, by iodoform-inunctions, 288
tuberculocidin, a remedy for, 441
Tuberculous arthritis, secondary miliary, 186
cattle, the disposal of, 357
fistulæ, lactic acid for, 552
kidney, extirpation of a, 76
leptomeningitis, sudden death from, 551
peritonitis from a surgical standpoint, 316
Tubes, Fallopian, can we drain the? 29
Tumenol in dermatologic practice, 438
Tumor, fibroid, of the uterus, 268
in the region of the right crus cerebri, 48
of the mid-brain and left optic thalamus, a case of, 29
of the thymus gland in connection with hemorrhagic purpura, 160
Tumors fibroid, of the uterus, 645
of both ovaries, removal of, 131
Tympanites and pregnancy, 156
Typhoid-bacilli and the bacilli coli communis, the differentiation of, 552
Typhoid fever and diphtheria, are they filth-diseases? 312
bacillus of, and the bacillus coli communis, distinction between, 216
causes of the diminished prevalence of, in Denver, 260
chlorine in, 132
Ehrlich's test of the urine in, 365
facial erysipelas complicating, 205
hemorrhage in, 139
intestinal antisepsis in, by means of bismuth subiodide and salol, 75
the dangers of antipyretics in, 457
the treatment of hemorrhage in, 53
treatment of, by cold baths, 594
Typhus fever in New York, 248

ULCER of the arm, 482
phimosis complicating simple venereal, 487
Ulcers of the leg, moist and painful, 302
Ulna, backward dislocation of, and fracture of the neck of the radius, 18

Umbilical cord, the care of, 41
Ununited fractures, 1
Unusual causes of jaundice, 324
Urates in the urine, forms of disease characterized by the presence of, 281
Urethra, female, malignant disease of, 587
Uric acid and rheumatism, 330, 417
in the urine, forms of disease characterized by the presence of, 281
is it a prime or sole factor in the causation of rheumatism? 111, 185
Urinary fistula following supra-pubic cystotomy, 187
organs, surgical diseases of, 567
ptomaïnes of exophthalmic goiter, 300
Urine, albumin in, an easy method of estimating the percentage of, 52
Ehrlich's test of, in typhoid fever, 365
forms of diseases characterized by the presence of bile, urates, and uric acid in the, 281
hydrogen disulphide in, a case of, 154
incontinence of, prescription for, 244
specimens of, desired, 54
the percentage of albumin in, 85
toxicity of, in diseases of the liver, 187
the reaction of, with ether, 491
Uteri, cervix, a unique case of polypus of the, 239
Uterine and abdominal tolerance in pregnant women, 468
complications of influenza, 324
dilatation and drainage following endometritis, 404
Uterus, fibroid tumor of the, 268
tumors of the 645
gravid, a case of retroversion of, in a primipara, 492
hysterectomy for carcinoma of, 493
removal of, in puerperal peritonitis, 271
the microscope as an aid to diagnosis in diseases of the, 477

VACCINATION, 537
Value of a trade-mark, 386
Valvular lesions of the heart, the treatment of, 135
Vas deferens, inflammation of, without epididymitis, 48
Venereal ulcer, phimosis complicating simple, 487
Vertigo, laryngeal, or laryngeal epilepsy, a case of so-called, 318
of arterio-sclerosis, 715
the clinical and pathologic significance of, 477
Vesiculæ seminales, gonorrhea of the (spermato-cystitis), 508
Viburnum prunifolium; its physiologic action and therapeutic applications, 371
Vice and depravity, surgical instruction for the encouragement of. 383
Virus of hydrophobia, the influence of the gastric juice upon, 466
Visceral hemorrhages in still-born children, 160
Volvulus from violent exercise; laparotomy; death, 103
Vomiting after operations, 332
relief of, 272

WALLIAN, SAMUEL S., M.D., a national system of sanatoria; a plea and a prophecy, 623
in re hydrogen dioxide, 125
Walton, G. M., M.D., and C. F. Carter, M.D., eye-strain and headache, 309
Wanted, a cure, 108
Washed air for hospitals and assembly rooms, 277
Weiland, Carl, M.D., a critical study of the main defects of Javal's ophthalmometer, 626
Whooping-cough, antipyrin in, 48
the vapor of naphthalin in the treatment of, 76
Wilkins, George, M.D., the treatment of typhoid fever by cold baths, 594
Will the general practitioner cease to exist and his place be taken by specialists? 578
Winckel's anterior colporrhaphy, 322
Woman, at what age may she marry? 134
Wood, Dr., a correction from, 641
Word-blindness, 521
Worthington, R. H., M.D., fistula in ano 573
systematic examination for rectal disease, 197
Wright, Jonathan, M.D., a case of primary lupus of the pharynx, 36
Wyeth's method, amputation at the hip-joint by, 349

XERODERMA pigmentosum, two cases, 435

YOUNG, J. K., a case of bilateral lumbar abscess associated with Pott's disease, 65
